ABSTRACT

This paper exhibits a prologue to box tail UAV innovation and an outline of ebb and flow look into endeavors right now. Box tail innovation offers high lifting capacities, diminishing wing vortices and less unpredictable flight controls. Instead of utilizing aileron a lift we are going for elevons. Anyway at the present condition of innovation the plan of half and half box tail presents numerous difficulties and requires imaginative answers for both the airplane arrangement just as vitality stockpiling framework. For this solar panel (sun oriented boards) are implemented to give power. The airplane's shut wing configuration, named a "twofold box tail", is proposed to bring down initiated drag and be slow down safe, alongside limit layer control techniques. The twin level tails articulate, giving synchronous power over roll and pitch.

CHAPTER 1

INTRODUCTION

1.1 History:

In recent years, awareness of the potential of unmanned aerial vehicle(UAVs) for multiple missions has increased the level of research into improving UAV design and technologies. Studies found that electric or fossil fuel powered UAVs have inadequate flying hours for various tasks. Increased focus has been placed recentlyon developing hybrid powered electric UAVs, especially with the combination of solar energy and battery or fuel cells in a battery powered system. The current study of our project considers various power systems and examines the design and development of solar cells in battery powered UAVs. A synthesized UAV mathematical design model suitable for sizing and configuration design of small solar powered and battery powered electric systems was developed to fulfil the previously mentioned requirements.

The design of UAV requires innovative solutions for both the aircraft configuration as well as the propulsion and energy storage systems. To enable a flight endurance, the propulsion system needs to be able to provide the power for the flight day and night , which leads to very heavy fuel load when using a non regenerative system. If a regenerative system is used however, the power train needs doubled.

An unmanned aerial vehicle (UAV) (or uncrewed aerial vehicle, commonly known as a drone) is an aircraft without a human pilot on board and a type of unmanned vehicle. UAVs are a component of an unmanned aircraft system (UAS), which include a UAV, a ground-based controller, and a system of communications between the two. The flight of UAVs may operate with various degrees of autonomy either under remote control by a human operator or autonomously by onboard computers.

Compared to crewed aircraft, UAVs were originally used for missions too "dull, dirty or dangerous" for humans. While they originated mostly in military applications, their use is rapidly expanding to commercial, scientific, recreational, agricultural, and other applications, such as policing and surveillance, product

deliveries, aerial photography, infrastructure inspections, smuggling, and drone racing. Civilian UAVs now vastly outnumber military UAVs, with estimates of over a million sold by 2015. Multiple terms are used for unmanned aerial vehicles, which generally refer to the same concept. The term unmanned aircraft system (UAS) was adopted by the United States Department of Defence (DoD) and the United States Federal aviation administration in 2005 according to their Unmanned Aircraft System Roadmap 2005–2030. The International Civil Aviation Organization (ICAO) and the British Civil Aviation Authority adopted this term, also used in the European Union's Single European Sky(SES) Air Traffic Control (ATC) Research (SESAR Joint Undertaking) roadmap for 2020A box wing configuration assures saving in fuel consumption because of lower induced drag. In a study the box wing configuration has proven to consume 9% less fuel as a result of 14% increase in the glide ratio. Also, because of the improved lift to drag ratio, we can expect lesser noise by the UAV making the surveillance mission without making noise. In practise, this design could potentially have other advantages and disadvantages including altered pilot handling characteristics.

This term emphasizes the importance of elements other than the aircraft. It includes elements such as ground control stations, data links and other support equipment. A similar term is an unmanned-aircraft vehicle system (UAVS), remotely piloted aerial vehicle (RPAV), remotely piloted aircraft system (RPAS).

1.2 UAVs typically fall into one of six functional categories:

- Target and decoy – providing ground and aerial gunnery a target that simulates an enemy aircraft or missile.
- Reconnaissance – providing battlefield intelligence.
- Combat – providing attack capability for high-risk missions Unmanned Combat Aerial vehicle (UCAV)).
- Logistics – delivering cargo.
- Research and development – improve UAV technologies.
- Civil and commercial UAVs – agriculture, aerial photography, data collection.
- Vehicles can be categorized in terms of range/altitude.

- Hand-held 2,000 ft (600 m) altitude, about 2 km range.
- Close 5,000 ft (1,500 m) altitude, up to 10 km range.
- NATO type 10,000 ft (3,000 m) altitude, up to 50 km range.
- Tactical 18,000 ft (5,500 m) altitude, about 160 km range.
- MALE (Medium altitude long endurance) up to 30,000 ft (9,000 m) and range over 200 km.
- HALE (High altitude long endurance) over 30,000 ft (9,100 m) and indefinite range.
- Hypersonic high-speed, supersonic (Mach 1–5) or hypersonic (Mach 5+) 50,000 ft (15,200 m) or suborbital altitude, range over 200 km.
- Orbital low earth orbit (Mach 25+).
- CIS Lunar Earth-Moon transfer.
- Computer Assisted Carrier Guidance System (CACGS) for UAVs.

1.3 Other categories include:

- Hobbyist UAVs – which can be further divided into o Ready-to-fly (RTF)/Commercial-off-the-shelf (COTS) o Bind-and-fly (BNF) – require minimum knowledge to fly the platform o Almost-ready-to-fly (ARF)/Do-it-yourself (DIY) – require significant knowledge to get in the air o Bare frame – requires significant knowledge and your own parts to get it in the air.
- Midsize military and commercial UAVs.
- Large military-specific UAVs.

1.4 Classifications according to aircraft weight are quite simpler:

- Micro Air Vehicle (MAV) – the smallest UAVs that can weigh less than 1g
- Miniature UAV (also called SUAS) – approximately less than 25 kg
- Heavier UAVs
- Stealth combat UAVs.
- Crewed aircraft transformed into uncrewed (and Optionally Piloted UAVS or OPVs)

1.5 Design objective:

This paper exhibits a prologue to box tail UAV innovation and an outline of ebb and flow look into endeavors right now. Box tail innovation offers high lifting capacities, diminishing wing vortices and less unpredictable flight controls. Insteadof utilizing aileron a lift we are going for Elevons. Anyway at the present condition of innovation the plan of half and half box tail presents numerous difficulties and requires imaginative answers for both the airplane arrangement just as vitality stockpiling framework. For this solar panel (sun oriented boards) are implemented to give power. The airplane's shut wing configuration, named a "twofold box tail", is proposed to bring down initiated drag and be slow down safe, alongside limit layer control techniques. The twin level tails articulate, giving synchronous power over roll and pitch.

CHAPTER 2

LITERATURE REVIEW

2.1 Development of design methodology for a small solar powered UAV:

This paper presents preliminary design of a joined wing high altitude long endurance UAV. The wing structural weight will be reduced and also stiffness is added by closed the wing box. The current study considers the pros and cons of various power systems and examines the design and development of solar cells in battery-powered UAVs.

A general analysis work was conducted on the mathematical design model that covers both solar (solar- and battery-powered) and nonsolar (battery-powered) UAV sizing. The simulation was also subject to UAVs that can perform a minimum of 9 hours of flight operation beginning at 12 noon on 22 June 2014 at Cranfield, United Kingdom, with an iteration sizing accuracy of 1cm or 1g.

The relationship between the mass of the payload and battery of both solar and nonsolar UAVs (Figure 7) indicates that the mass of the battery gradually increases with payload. This result can be attributed to the minimum size of the battery pack, which comes in multiples of 150g± 10%. This finding proves another advantage of applying the electric propulsion modeling as part of this design modeling, where sizing small UAVs provides an accurate weight prediction.

2.2 Preliminary design of a joined wing HALE UAV:

HALE UAVs could provide an improved service and/or flexibility over existing systems for a vast number of civil applications, ranging from border patrol and coastal surveillance over monitoring of natural disasters, meteorology and cartography to highly flexible telecommunication relay stations. Airborne platforms that remain a loft for weeks to months at altitudes between 15 and 22 km namely

provide an advantage over satellite systems in terms of reduced costs, increased flexibility and higher precision.

However, at the current state of technology, the design of HALE UAVs poses many challenges and requires innovative solutions for both the aircraft configuration as well as the propulsion and energy storage systems If a regenerative system is used however, the power train needs to be doubled. One system is needed for the daytime and a second one provides the power for the flight throughout the night. As a consequence of this unavoidable redundancy, a low propulsive power is a key driver in the design.

Not only will the Oswald efficiency factor be increased to values in the order of1.2, the wing structural weight will be reduced too, seen the stiffness added by closing the wing box. As the low power requirement, a key driver for HALE UAVs, leads to low cruise speeds and high wing surfaces, the joined-wing potentially offers a significant benefit for this particular application. In a next step, a more detailed assessment of the aerodynamic and structural characteristics of the wing will be made. The refined results will then be used to iterate on the overall design of the UAV.

2.3 Design and optimization of a MALE UAV wingbox structure:

The latest designs and innovations in structures and materials have been critical to the improvement of aircraft performance. Lightweight panels and composite materials have allowed designers to lower aircraft structural weight while still maintaining the required stiffness and integrity associated with metallic structures. Improving the weight of an aircraft plays an important role in reducing operating costs, and improving range and efficiency.

An optimization implies that the design concept will not only meet the set specification, but does so when a target criterion is imposed. In this research project the target was to obtain a minimal structural mass while still maintaining a positive Margin-of-Safety (MOS). This ensured that the lightweight structures would still have the capability to support the aircraft design loads.

The sandwich panel designs demonstrated the lowest wing box mass within the acceptable safety limits. As expected the greatest panel thickness and mass was located at the wing root, which experienced the greatest loading and resultant stress. The use of ply drops allowed for the large reduction in panel height across the span. This allowed for a unique structural solution to be obtained at each of the three wing locations (root, midpoint and tip).

The wingbox was designed to incorporate an I-beam wing spar (figure 13). This beam was able to provide the greatest beam stiffness and strength while still having the lightest weight. Each of the beam dimensions was used as a sizing variable to obtain the lowest possible beam mass.

2.4 Multi-objective optimization of the composite wing box of solar powered HALE UAV:

The main goal of this work is to design the composite wing box of the SHAMPO's configuartion that ensures a high strength to weight ratio, compliance with regulatory requirements and respects the constraints imposed a priori, including maximum wing-tip deflection, mass minimization, buckling and impact threshold limit. As it is worded, the multi-constraints design problem coupled with mass minimization becomes a Multi-objective Optimization problem. To achieve this goals, several different tools, both for design and optimization, have been developed and validated before being used for the final design.

A Genetic Algorithm has been developed to optimize the wing structure of innovative composite aircraft. A set of penalty functions has been activated during the optimization process in order to guarantee adequate stiffness and strength requirements and to avoid local or global buckling. A limit of 3000 με has been considered to cope with static and fatigue behaviour of damaged composite structures. An optimal lay-up configuration has been identified for a solar powered HALE UAV. A maximum deflection of 6.81 m is reached at the ultimate load; the optimized wing box weight is 160 Kg with maximum number of plies of 56 at the root section. The results are in good agreement with those reported in literature for same kind of aircraft.

2.5 Structural and aeroelastic design of a joined wing UAV:

The ability to fly nonstop for extended periods of time at very high altitudes has been an ongoing goal of the aeronautics community. The characteristics of such an aircraft would allow it to perform a varietyof missions for a host of possible users. Potential missions include military reconnaissance, civil border patrol, environmental and weather monitoring, traffic control, and a wide variety of civil communication applications. The aircraft desired would surely be unmanned, and capable of continuous operation for weeks, months, or even years. This type of UAV would be capable of performing many of the tasks that small low earth orbit satellites presently perform, but at a substantially reduced cost.

Results of this study showed the impact of power system component performance and mission conditions on UAV aircraft size. The most significant reduction in aircraft size was found to occur by increasing the energy storage (fuel cells in this case) specific energy, whereas the effects of PV module and power electronics efficiency and mass play a marginal role in comparison. Flight altitude, flight latitude, time of year, and payload mass also play significant roles in determining aircraft size. It was found that an energy storage specific energy of 250- 500 Whr/kg is required to enable most useful missions, and that operation in the winter at northern latitudes may not be possible. Also, it is concluded that PV cells with AM0 efficiencies greater than - 12% , possibly even thin-film PV cells, are suitable for solar-powered UAV use.

Results for the following analysis can be separated into two categories; the first considers the impact of varying the power system components, the second considers the impact of varying mission requirements.

CHAPTER 3

RESEARCH METHODOLOGY

3.1 Types of tail used in UAV:

- Conventional tail
- V- Tail
- T- Tail

3.1.1 Conventional Tail:

The conventional tail design is the most common form. It has one vertical stabilizer placed at the tapered tail section of the fuselage and one horizontal stabilizer divided into two parts, one on each side of the vertical stablilzer. For many airplanes, the conventional arrangement provides adequate stability and control with the lowest structural weight.

Conventional tail configurations are the most common configuration used in UAVs.

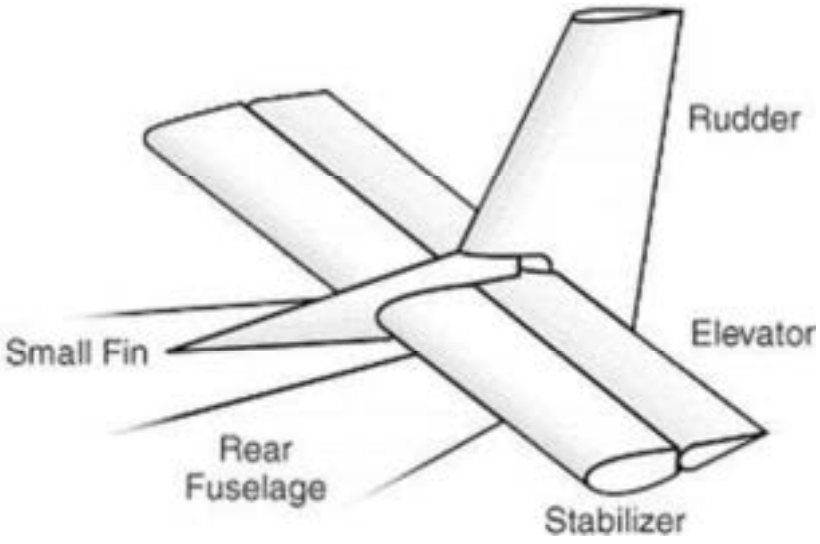

Fig-3.1(Conventional Tail)

3.1.2 V- Tail:

The V-Tail, sometimes called the "butterfly" tail, has had limited application in airplane design, the most significant of which has been by the Beech Company in the Beech-craft Bonanza V-35. Clearly, the usual definition of horizontal and vertical stabilizers has no application to the V tail. The intended advantage of the V-tail design is that two surfaces might serve the same function as the three required in the conventional tail and its variants. Removal of one surface then would reduce the drag of the tail surfaces as well as the weight of the tail region. However, wind tunnel studies by the National Advisory Committee on Aeronautics (NACA) have shown that for the V tail to achieve the same degree of stability as a conventional tail, the area of the V tail would have to be about the same size as that of the conventional tail.

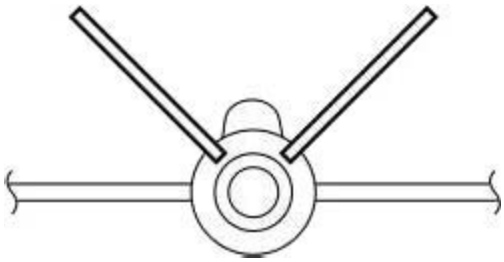

Fig-3.2(V-Tail)

3.1.3 T- Tail:

In the T-tail design, a common variation of the conventional tail, the horizontal stabilizer is positioned at the top of the vertical stabilizer. The horizontal stabilizer is then above the propeller flow, or prop wash, and the wing wake. Because the horizontal stabilizer is more efficient, it can therefore be made both smaller and lighter. The placement of the horizontal stabilizer on top of the vertical stabilizer can also make the vertical stabilizer more aerodynamically efficient. By making the vertical stabilizer more effective, its size may be reduced. However, the horizontal stabilizer in the T-tail layout imposes a bending and twisting load on the vertical stabilizer,

requiring a stronger, and therefore, a heavier, structure. These loads are avoided in the conventional design. There is also the possibility that at the high pitch angle usually associated with landing the airplane, the horizontal stabilizer of the T tail will be immersed in the slower and more turbulent flow of the wing wake. In some cases, it is possible to compromise severely the control function of the horizontal tail. Nevertheless, the T tail is the second-most common tail design after the conventional. Both major American transport plane builders, Boeing and McDonnell-Douglas, use the T-tail design.

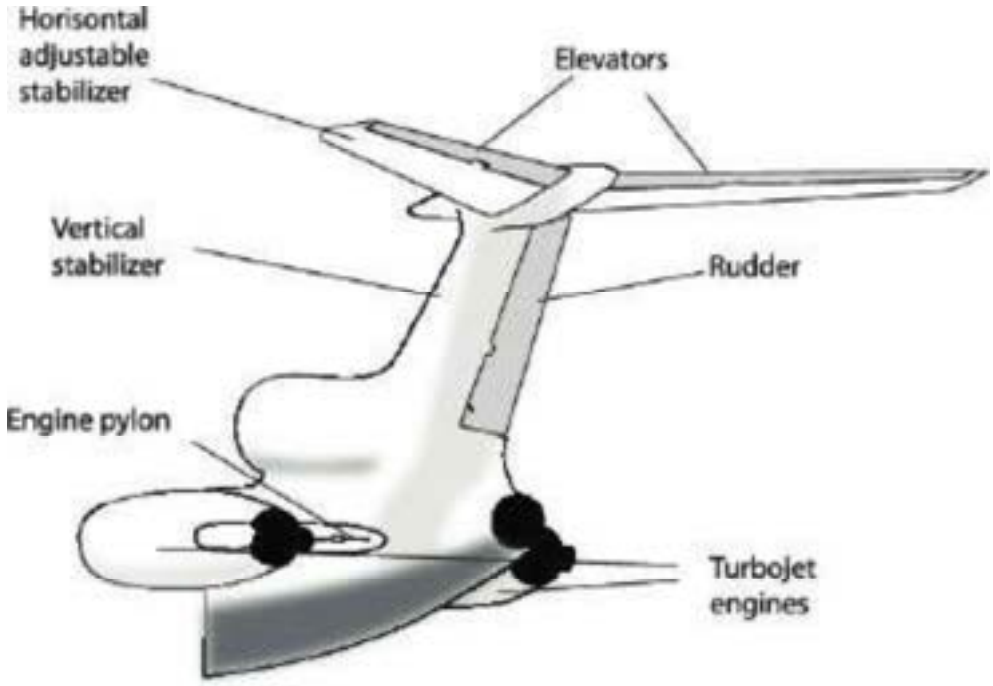

Fig-3.3(T-Tail)

3.2 Boxtail configuration:

The boxtail configuration lowers induced drag (the drag due to lift) to the theoretical limit. Its 3-D span efficiency is 1.46 times that of a normal wing of the same span, in a strong, compact form more capable of higher speeds than a long, glider-style wing. Decreasing the induced drag of an airplane provides benefits in climb, at lower speeds, when racing or maneuvering, at higher weights, and at higher altitudes.

The Synergy configuration eliminates complexity because none of our simple, seamless flight surfaces have any controls or spanwise gaps in them. Two moving surfaces provide a majority of flight control. Like a flying wing, which is a less efficient configuration than DBT, pitch and roll controls are combined. We don't have separate elevators and ailerons; our two elevons are just simple, one-piece airfoils, supported at both ends and rotated for control. (Thanks to its natural turn coordination, Synergy's twin, V-tail-mounted rudders are rarely required in flight, but yes, we have (two) rudders on the full size aircraft!) Reduced complexity translates directly into reduced weight and reduced cost.

Fig-3.4(Boxtail)

Laminar flow and high span efficiency allows a bigger wing in comparison to typical high-performance designs. Providing increased fuel storage and slower landings, the wings can be stronger and stiffer for a given span loading. The twisting tendency of a swept wing is balanced out of the system under G-loading by an always-proportionate, opposing down force from the tails.

Double boxtail configuration creates constructive, beneficial wing- tail interaction, rather than (destructive) "biplane interference", allowing wing and tail to cooperate together for lower drag. In addition, all airfoil surfaces continue the low pressure or high pressure famous interference drag problem common to box wing designs. Every wingtip or stabilizer tip is a drag source on an airplane.

CHAPTER 4

MATERIAL USED

4.1 Material used in boxtail UAV:

- Brushless motor
- Electronic Speed Controller(ESC)
- Servo motor
- Propeller
- Lipo Battery
- Coro Sheet
- Transmitter and Receiver
- Solar panel
- Solar Controller

4.1.1 Brushless motor:

Brushless motors can be constructed in several different physical configurations: In the 'conventional' (also known as in runner) configuration, the permanent magnets are part of the rotor. Three stator windings surround the rotor. In the out runner (or external-rotor) configuration, the radial-relationship between the coils and magnets is reversed; the stator coils form the center (core) of the motor, while the permanent magnets spin within an overhanging rotor which surrounds the core. The flat or axial flux type, used where there are space or shape limitations, uses stator and rotor plates, mounted face to face. Out runners typically have more poles, set up in triplets to maintain the three groups of windings, and have a higher torque at low RPMs. In all brushless motors, the coils are stationary.

Although efficiency is greatly affected by the motor's construction, the Wye winding is normally more efficient. In delta-connected windings, half voltage is applied across the windings adjacent to the driven lead (compared to the winding directly between the driven leads), increasing resistive losses. In addition, windings

can allow high-frequency parasitic electrical currents to circulate entirely within the motor. A Wye-connected winding does not contain a closed loop in which parasitic currents can flow, preventing such losses.

A brushless DC electric motor (BLDC motor or BL motor), also known as electronically commutated motor (ECM or EC motor) and synchronous DC motors, are synchronous motors powered by direct current (DC) electricity via an inverter or switching power supply which produces electricity in the form of alternating current (AC) to drive each phase of the motor via a closed loop controller. The controller provides pulses of current to the motor windings that control the speed and torque of the motor.

The advantages of a brushless motor over brushed motors are high power-to-weight ratio, high speed, electronic control, and low maintenance. Brushless motors find applications in such places as computer peripherals (disk drives, printers), hand-held power tools, and vehicles ranging from model aircraft to automobiles.

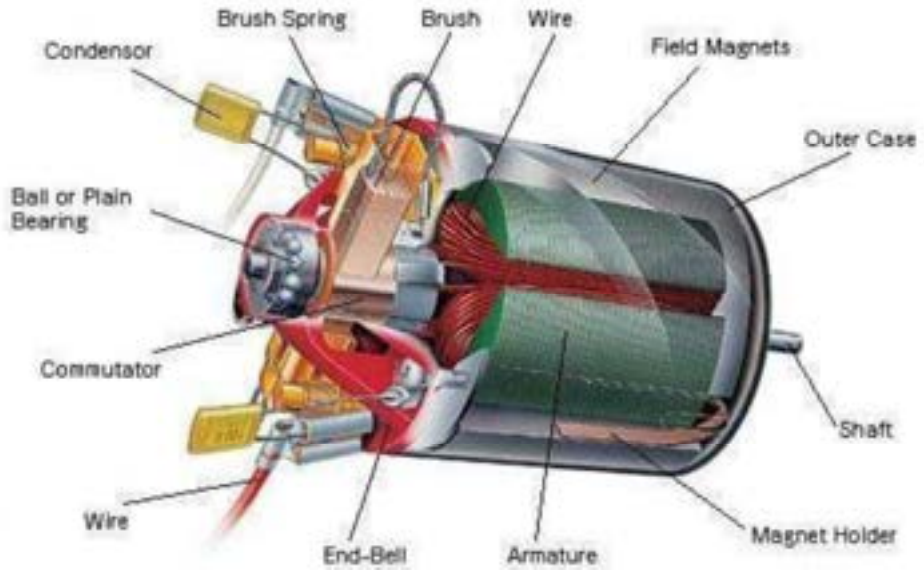

Fig-4.1(Brushless Motor)

4.1.1 Electronic Speed Controller (ESC):

An electronic speed control or ESC is an electronic circuit that controls and regulates the speed of an electric motor. It may also provide reversing of the motor and dynamic braking. Miniature electronic speed controls are used in electrically powered radio controlled models. Full-size electric vehicles also have systems to control the speed of their drive motors.

An electronic speed control follows a speed reference signal (derived from a throttle lever, joystick, or other manual input) and varies the switching rate of a network of field effect transistors (FETs). By adjusting the duty cycle or switching frequency of the transistors, the speed of the motor is changed. The rapid switching of the transistors is what causes the motor itself to emit its characteristic high-pitched whine, especially noticeable at lower speeds.

Different types of speed controls are required for brushed DC motors and brushless DC motors. A brushed motor can have its speed controlled by varying the voltage on its armature. (Industrially, motors with electromagnet field windings instead of permanent magnets can also have their speed controlled by adjusting the strength of the motor field current.) A brushless motor requires a different operating principle. The speed of the motor is varied by adjusting the timing of pulses of current delivered to the several windings of the motor.

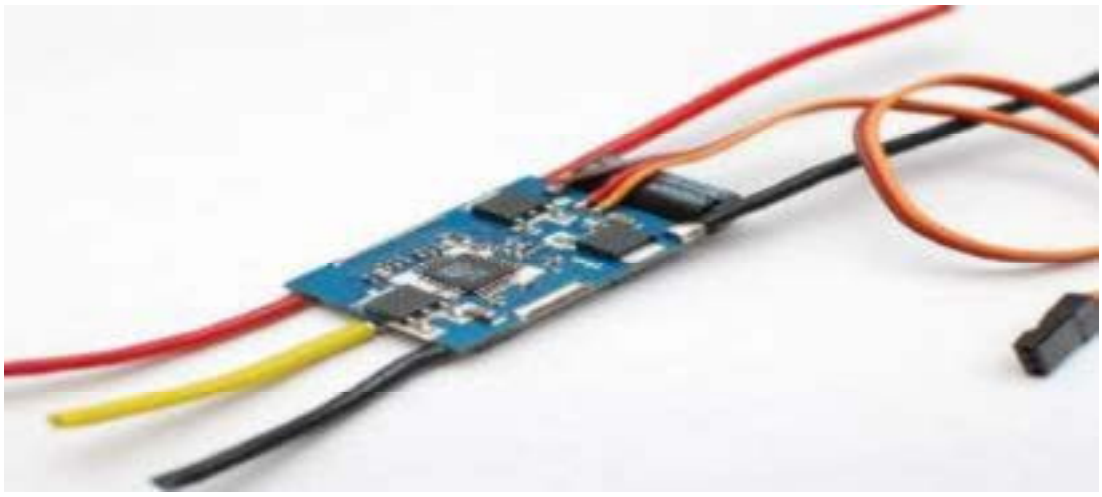

Fig-4.2(ESC)

4.1.2 Servo Motor:

A servomotor is a rotary actuator or linear actuator that allows for precise control of angular or linear position, velocity and acceleration. It consists of a suitable motor coupled to a sensor for position feedback. It also requires a relatively sophisticated controller, often a dedicated module designed specifically for use with servomotors.

The motor is paired with some type of position encoder to provide position and speed feedback. In the simplest case, only the position is measured. The measured position of the output is compared to the command position, the external input to the controller. If the output position differs from that required, an error signal is generated which then causes the motor to rotate in either direction, as needed to bring the output shaft to the appropriate position. As the positions approach, the error signal reduces to zero and the motor stops.

The very simplest servomotors use position-only sensing via a potentiometer and bang-bang control of their motor; the motor always rotates at full speed (or is stopped). This type of servomotor is not widely used in industrial motion control, but it forms the basis of the simple and cheap servos used for radio-controlled models.

Fig-4.3(Servo motor)

Servomotors may use resistive potentiometers as their position encoder. These are only used at the very simplest and cheapest level, and are in close competition with

stepper motors. They suffer from wear and electrical noise in the potentiometer track. Although it would be possible to electrically differentiate their position signal to obtain a speed signal, PID controllers that can make use of such a speed signal generally warrant a more precise encoder.

4.1.3 Propeller:

In aeronautics, a propeller, also called an airscrew, converts rotary motion from an engine or other power source into a swirling slipstream which pushes the propeller forwards or backwards. It comprises a rotating power-driven hub, to which are attached several radial airfoil-section blades such that the whole assembly rotates about a longitudinal axis. The blade pitch may be fixed, manually variable to a few set positions, or of the automatically-variable "constant-speed" type.

Very small pitch and helix angles give a good performance against resistance but provide little thrust, while larger angles have the opposite effect. The best helix angle is when the blade is acting as a wing producing much more lift than drag. However, 'lift-and-drag' is only one way to express the aerodynamic force on the blades. To explain aircraft and engine performance the same force is expressed slightly differently in terms of thrust and torque since the required output of the propeller is thrust. Thrust and torque are the basis of the definition for the efficiency of the propeller as shown below. The advance ratio of a propeller is similar to the angle of attack of a wing.

Fig-4.4(Propeller)

Propellers are similar in aerofoil section to a low-drag wing and as such are poor in operation when at other than their optimum angle of attack. Therefore, most propellers use a variable pitch mechanism to alter the blades' pitch angle as engine speed and aircraft velocity are changed.

4.1.4 Li-Po Battery:

A lithium polymer battery, or more correctly lithium-ion polymer battery (abbreviated as LiPo, LIP, Li-poly, lithium-poly and others), is a rechargeable battery of lithium-ion technology using a polymer electrolyte instead of a liquid electrolyte. High conductivity semisolid (gel) polymers form this electrolyte. These batteries provide higher specific energy than other lithium battery types and are used in applications where weight is a critical feature, like mobile devices and radio-controlled aircraft.

Just as with other lithium-ion cells, LiPos work on the principle of intercalation and de-intercalation of lithium ions from a positive electrode material and a negative electrode material, with the liquid electrolyte providing a conductive medium. To prevent the electrodes from touching each other directly, a micro porous separator is in between which allows only the ions and not the electrode particles to migrate from one side to the other.

Fig-4.5(Lipo Battery)

LiPo batteries are now almost ubiquitous when used to power radio-controlled aircraft, radio-controlled cars and large scale model trains, where the advantages of lower weight and increased capacity and power delivery justify the price. Test reports warn of the risk of fire when the batteries are not used in accordance with the instructions.

4.1.5 Transmitter and Receiver:

In electronics and telecommunications a transmitter or radio transmitter is an electronic device which produces radio waves with an antenna. The transmitter itself generates a radio frequency alternating current, which is applied to the antenna. When excited by this alternating current, the antenna radiates radio waves.

Transmitters are necessary component parts of all electronic devices that communicate by radio, such as radio and television broadcasting stations, cell phones, walkie-talkies, wireless computer networks, Bluetooth enabled devices, garage door openers, two-way radios in aircraft, ships, spacecraft, radar sets and navigational beacons. The term transmitter is usually limited to equipment that generates radio waves for communication purposes; or radiolocation, such as radar and navigational transmitters. Generators of radio waves for heating or industrial purposes, such as microwave ovens or diathermy equipment, are not usually called transmitters, even though they often have similar circuits.

Fig-4.6Transmitter and Receiver)

In radio communications, a radio receiver, also known as a receiver, wireless or simply radio is an electronic device that receives radio waves and converts the information carried by them to a usable form. It is used with an antenna. The antenna intercepts radio waves (electromagnetic waves) and converts them to tiny alternating currents which are applied to the receiver, and the receiver extracts the desired information. The receiver uses electronic filters to separate the desired radio frequency signal from all the other signals picked up by the antenna, an electronic amplifier to increase the power of the signal for further processing, and finally recovers the desired information through demodulation.

4.1.6 Coro Sheet:

Coroplast, or Coro, which is a brand name given to Fluted PolyPropylene sheets, is a lightweight, sturdy, resilient material extensively used in packaging and advertising. Coroplast sheets have parallel hollow flutes which make the material very light and strong. The material usually crushes, instead of breaking upon impact. Coro bonds well with epoxy hot glue, and CyanoAcrylate (CA) Adhesive. These characteristics make it suitable for RC applications. This material is of choice for making S.P.A.D. (Simple Plastic Airplane Designs). The fluted design helps in hinging and folding and curving.

Fig-4.7(Coro sheet)

This material is commonly used to erect commercial, political or other types of signs and for constructing plastic containers and reusable packaging. It is widely used in the signwriting industry for making signs for real estate sales, construction sites and promotions.

The last decade has found its increasing use among guinea pig, rabbit, domesticated hedgehog and other small pet enthusiasts as components of DIY cages. Additionally, it is used by members of the remote-controlled aircraft community to build nearly indestructible SPAD model aircraft.

4.1.7 Solar Panel:

Solar power is the conversion of energy from sunlight into electricity, either directly using photovoltaic (PV), indirectly using concentrated solar power, or a combination. Concentrated solar power systems use lenses or mirrors and solar tracking systems to focus a large area of sunlight into a small beam. Photovoltaic cells convert light into an electric current using the photovoltaic effect.

Photovoltaic were initially solely used as a source of electricity for small and medium-sized applications, from the calculator powered by a single solar cell to remote homes powered by an off-grid rooftop PV system. Commercial concentrated solar power plants were first developed in the 1980s. As the cost of solar electricity has fallen, the number of grid-connected solar PV systems has grown into the millions and utility-scale photovoltaic power stations with hundreds of megawatts are being built. Solar PV is rapidly becoming an inexpensive, low-carbon technology to harness renewable energy from the Sun.

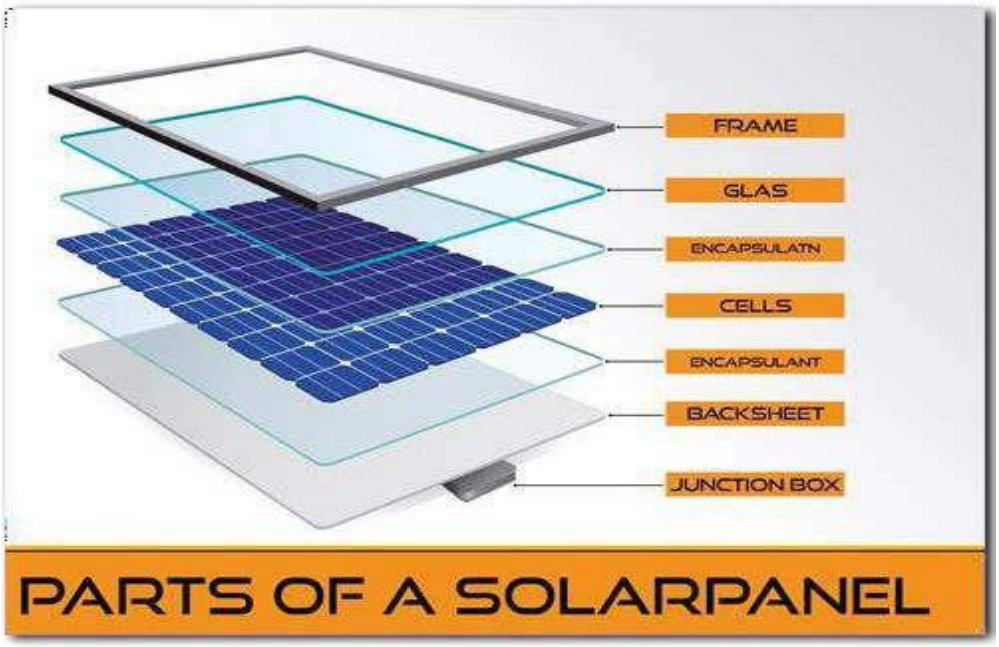

Fig-4.8(solar panel)

Emerging, third generation solar technologies use advanced thin-film cells. They produce a relatively high-efficiency conversion for the low cost compared to other solar technologies. Also, high-cost, high-efficiency, and close-packed rectangular multi-junction (MJ) cells are preferably used in solar panels on spacecraft, as they offer the highest ratio of generated power per kilogram lifted into space. MJ-cells are compound semiconductors and made of gallium arsenide (GaAs) and other semiconductor materials. Another emerging PV technology using MJ-cells is concentrator photovoltaic (CPV).

4.1.8 Solar Controller:

A solar controller is an electronic device that controls the circulating pump in a solar hot water system to harvest as much heat as possible from the solar panels and protect the system from overheating. The basic job of the controller is to turn the circulating pump on when there is heat available in the panels, moving the working fluid through the panels to the heat exchanger at the thermal store. Heat is available whenever the temperature of the solar panel is greater than the temperature of the water

in the heat exchanger. Overheat protection is achieved by turning the pump off when the store reaches its maximum temperature and sometimes cooling the store by turning the pump on when the store is hotter than the panels.

Fig-4.9(Solar controller)

One claimed advantage of PV power is that it reduces the overall carbon emissions associated with operating the system since it avoids the need to supply this energy from fossil sources. However, the energy required to operate the system is very small in comparison to the energy produced by the system and the carbon emissions reduction of adding PV power fractional.

The most practical benefit of a PV powered controller is the resultant simplicity of the overall system. Rather than using complex algorithms based on store and panel temperatures, the pump is driven directly by the PV panel: when the sun shines, the pump runs. In practice this is nearly (90-99%) as efficient a practical control algorithm as most others achieve and has obvious advantages for reduced system complexity.

The benefits of a PV powered solar controller comes at a cost in reduced system performance in the range of 1-10%. This is due to heat losses at times when the panel may be hotter than the water store but there is insufficient sunlight to power the pump.

CHAPTER 5

DESIGN METHODOLOGY

5.1 Design Specification:

1. Length of the UAV	52cm
2. Breadth of the UAV	5cm
3. Wing span	90cm
4. Weight of the UAV	850g
5. Volume of the fuselage	4.5cm
6. Endurance	10-15mins

5.2 Model constructions:

5.2.1 Over View:

To construct the model and also maintaining low weight, coro sheet is used. Firstly the model frame is built. To construct the model frame, airfoil sections are cut from coro sheet and these sections configure overall shape of the plane and then it is covered to complete the model. Electronic instruments are mounted in the central part of the wing .The model has two servo motors that are connected to elevons. This model is a radio control model. The shape of tail portion is closed box model. This model also called as double box tail UAV.

5.2.2 Fuselage and Tail construction:

The fuselage had been designed by using the coro sheet. The sheet had cut in the chosen dimension and the fuselage had been mounted. And tail design also made by the same sheet in the Box tail configuration.

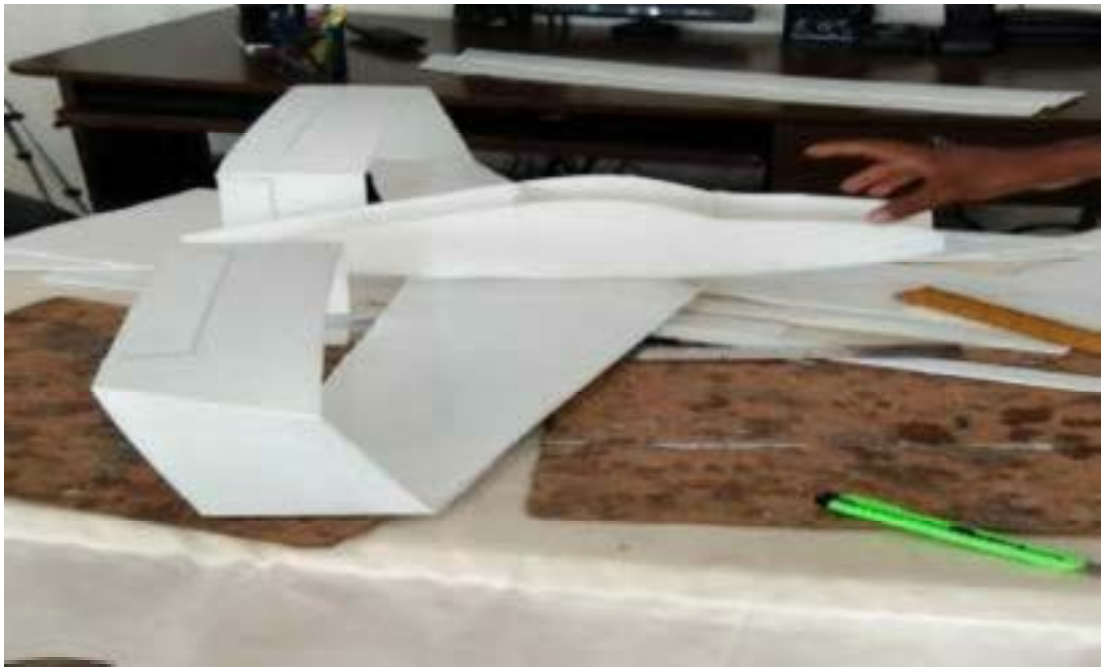

Fig-5.1(Fuselage construction)

Fig-5.2(Fuselage Construction)

5.2.3 Wing Configuration:

In wing design by using the coro sheet. First to making the airfoil by using coro sheet by made the delta wing configuration. An airfoil-shaped body moving through a fluid produces an aerodynamic force. The component of this force perpendicular to the direction of motion is called lift. The component parallel to the direction of motion is called drag. Subsonic flight airfoils have a characteristic shape with a rounded leading edge, followed by a sharp trailing edge, often with a symmetric curvature of upper and lower surfaces. Foils of similar function designed with water as the working fluid are called hydrofoils.

Fig-5.3(Wing Design)

Fig-5.4(Wing Construction)

The delta wing form has unique aerodynamic characteristics and structural advantages. Many design variations have evolved over the years, with and without additional stabilising surfaces. Its long root chord also allows a deeper structure for a given aerofoil section, providing more internal volume for fuel and other storage without a significant increase in drag. However, on supersonic designs the opportunity is often taken to use a thinner aerofoil instead, in order to actually reduce drag.

5.2.4 Electronic instrument mounted in UAV:

Electronic instruments are mounted in the central part of the wing. First the brushless motor to mount most forward or nose portion of the UAV. The lipo battery is mounted on back portion of the UAV. At the top of fuselage the solar panel is fixed at the back portion. The solar controller had mounted on front portion inside the fuselage.

Fig-5.5(Electronic Mounts)

5.2.5 Solar Panel Mounted:

At the top of the fuselage the solar panel is fixed at the back portion. The solar panel to connected by the solar controller. The battery also connected by the solar controller. The solar panel to provide the power source the battery has continuously be charged.

Fig-5.6(Solar panel mount)

5.3 Weight Estimation:

An aircraft's gross weight is limited by several weight restrictions in order to avoid overloading its structure or to avoid unacceptable performance or handling qualities while in operation.

Aircraft gross weight limits are established during an aircraft's design and certification period and are laid down in the aircraft's type certificate and manufacturer specification documents.

An aircraft's structural weight capability is typically a function of when the aircraft was manufactured, and in some cases, old aircraft can have their structural weight capability increased by structural modifications.

Total weight Wt = Wpayload + Wempty

Where,

I. Empty weight is only fixed wing UAV
II. Payload weight is solar panel, solar controller, LED light

Empty weight (W_o) =700gram

Payload weight (W_p) =150gram

Total weight of an UAV (W_t) =150+700

=850gram

5.4 Thrust Estimation:

Thrust is a reaction force described quantitatively by Newton's third law. When a system expels or accelerates mass in one direction, the accelerated mass will cause a force of equal magnitude but opposite direction on that system.

A fixed-wing aircraft generates forward thrust when air is pushed in the direction opposite to flight.

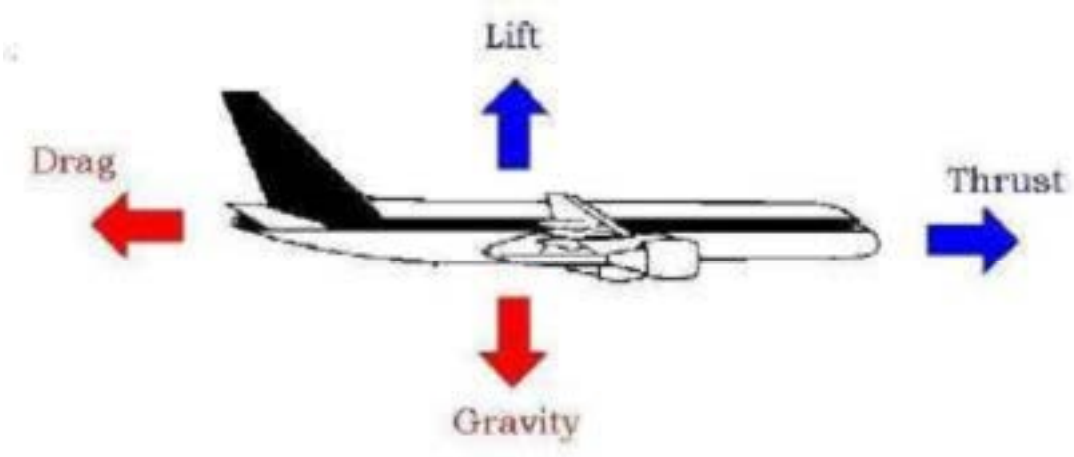

Fig-5.7(Aerodynamic forces)

In our design we are using the 1000kv Brushless motor and propeller size is 10*4.5 inch. It can produce 900 gram thrust, but our design weight only 850 gram. So it can produce high thrust.

To increase high thrust it can reduce motor kv and increase the propeller size.

5.5 Landing gear:

Landing gear is the undercarriage of an aircraft or spacecraft and may be used for either takeoff or landing. For aircraft it is generally needed for both. For aircraft, the landing gear supports the craft when it is not flying, allowing it to take off, land, and taxi without damage. Wheeled landing gear is the most common with skis or floats needed to operate from snow/ice/water and skids for vertical operation on land. Faster aircraft have retractable undercarriages, which fold away during flight to reduce drag.

Conventional landing gear, or tail wheel-type landing gear, is an aircraft undercarriage consisting of two main wheels forward of the centre of gravity and a small wheel or skid to support the tail. The term tail dragger is also used, although some claim it should apply only to those aircraft with a tailskid rather than a wheel.

Tricycle gear is a type of aircraft undercarriage, or landing gear, arranged in a tricycle fashion. The tricycle arrangement has a single nose wheel in the front, and two or more main wheels slightly aft of the center of gravity. Tricycle gear aircraft are the easiest to take-off, land and taxi, and consequently the configuration is the most widely used on aircraft.

In our design we are using tricycle landing gear arrangement.Tricycle gear aircraft are much less liable to 'nose over' as can happen if a taildragger hits a bump or has the brakes heavily applied. In a nose-over, the aircraft's tail rises and the propeller strikes the ground, causing damage.

Fig-5.8(Landing gear design)

CHAPTER 7

TESTING AND RESULT

7.1 Testing and Result:

Result of tests as follow: In the first test, model showed good maneuverability and acceptable stability properties of box tail UAV. Consequently, two side box tail configuration model the maximum speed was about 1.5m/s, and flying time was 15 minutes.

In the second test, the maximum speed was about 1m/s, and flying time was 10 minutes. The UAV showed a better stability with proper maneuverability.

CHAPTER 8

CONCLUSION

The goal was to design a Unmanned Aerial Vehical in boxtail configuration powered with solar panel. Consequently, two box shaped tail model were fabricated, both boxtail are fixed to make delta wing by using rods. To compute aerodynamic properties it is assumed that lift distribution is ideal.

In this box tail elevons are used as control surface to control the UAV. And also winglets are used to reduce wingtip vortices. Flight test proven that the stability properties become high when winglets should be used.

This design gives high performance and stability by using that delta wing. The small solar panel are used for this UAV which produces only less power. That we also using lipo battery to produce high power. The box tail was designed to give better performance which achieved a good stability and maneuvetability.

ABSTRACT

The propeller is the primary component of flying vehicles powered by electric motors, internal combustion engines, and turboprops for producing thrust. A propeller thrust is produced in the engine by effective spinning of the propeller through air for cost-effective and environmental friendly flight. Natural flyers like birds as well as aquatic animals like humpback whales effectively use its wings and flippers with its surface features for capturing its prey and escaping from their enemies. As part of this work, corrugations are established in the leading edges or in the suction surfaces of the propeller to modify the flow field prevailing over there. Because of the flow field, the surface corrugations or leading edge corrugations energize the boundary layer in the surfaces of the propeller by counter-rotating vortices which, in turn, delays the separation of the boundary layer from the surface. The performance parameters of the propeller such as thrust, torque, propeller efficiency, power consumption etc., are measured using propeller test rig. Depending on the location of surface or leading corrugations, the variations in the performance of the propeller are investigated for further optimization on the selection of better propeller to the applications of UAVs operating at low Reynolds No.

CHAPTER 1
INTRODUCTION

An Unmanned Aerial Vehicles capable of Vertical Take-Off and Landing (VTOL UAVs), are increasingly deployed for various applications such as surveillance, autonomous parcel delivery, oil and gas spill detection and firefighting. The development of Unmanned Aerial Vehicles (UAV) for civil and military applications has increased significantly over the last decade. More industries such as agricultural, educations, communications, and energy sector are becoming more courageous to venture into the utilizations of UAV to carry our various missions. As the advancement of technologies, the implementation of UAV may contribute to increase in productivity as well as reducing the risk, allowing replacement of manned mission. This is because UAVs are cost and maintenance friendly. Hence, it is very important to have high-performance UAV design so that it could deliver the mission efficiently.

An unmanned aerial vehicle (UAV) is an aircraft without a human pilot on board and a type of unmanned vehicle. UAVs are a component of an unmanned aircraft system (UAS); which include a UAV, a ground-based controller, and a system of communications between the two. The flight of UAVs may operate with various degrees of autonomy: either under remote control by a human operator or autonomously by onboard computers. Compared to crewed aircraft, UAVs were originally used for missions too "dull, dirty or dangerous" for humans. While they originated mostly in military applications, their use is rapidly expanding to commercial, scientific, recreational, agricultural, and other applications, such as policing and surveillance, product deliveries, aerial photography, infrastructure inspections, smuggling, and drone racing. Civilian UAVs now vastly outnumber military UAVs, with estimates of over a million sold by 2015.The term drone, more widely used by the public, was coined in reference to the early remotely-flown target aircraft used for practice firing of a battleship's guns, and the term was first used with the 1920s Fairey Queen and 1930's de Havilland Queen Bee target aircraft. These two were followed in service by the similarly-named Airspeed Queen Wasp and Miles Queen Martinet, before ultimate replacement by the GAF Jindivik.

The term unmanned aircraft system (UAS) was adopted by the United States Department of Defences (DoD) and the United States Federal Aviation Administration in 2005 according to their Unmanned Aircraft System Roadmap 2005–2030. The International Civil Aviation Organization (ICAO) and the British Civil Aviation Authority adopted this term, also used in the European Union's Single-European-Sky (SES) Air-Traffic-Management (ATM) Research (SESAR Joint Undertaking) roadmap for 2020. This term emphasizes the importance of elements other than the aircraft. It includes elements such as ground control stations, data links and other support equipment. A similar term is an unmanned-aircraft vehicle system (UAVS), remotely piloted aerial vehicle (RPAV), remotely piloted aircraft system (RPAS).

The performance of a UAV is significantly influenced by the efficiency of the propeller. Thus, it is very important to investigate the propeller performance to ensure that the design led to a reliable UAV performance. Generally, propeller used for UAVs operates at a very low Reynolds number, measured at the 75% chord of the propeller. Currently, most small UAVs use off-shelf propeller blade due to its availability and economical advantage. The process of selecting the best propeller may be tedious, as it need to be tested to fit the specification and requirements of the UAV. In addition, the selection for propeller blade are concentrated to conventional blade design. Unconventional blade designs such as slotted, serrated, tubercle and adaptive structure are less likely to be implemented as it need to be designed and fabricated independently based on the requirements of the flight. Slotted blade designs are proposed in this study to engaged novel blade design implementations for UAV.

Figure 1.1: DJI Mavic 2 pro drone

1.1 History:

The earliest recorded use of an unmanned aerial vehicle for war fighting occurred on July 1849, serving as a balloon carrier in the first offensive use of air power in naval aviation. Austrian forces besieging Venice attempted to launch some 200 incendiary balloons at the besieged city. The balloons were launched mainly from land; however, some were also launched from the Austrian ship SMS Volcano. At least one bomb fell in the city; however, due to the wind changing after launch, most of the balloons missed their target, and some drifted back over Austrian lines and the launching ship Volcano. UAV innovations started in the early 1900s and originally focused on providing practice targets for training military personnel. UAV development continued during World War I, when the Dayton-Wright Airplane Company invented a pilotless aerial torpedo that would explode at a present time.

The earliest attempt at a powered UAV was A. M. Low's "Aerial Target" in 1916. Nikola Tesla described a fleet of uncrewed aerial combat vehicles in 1915. Advances followed during and after World War I, including the Hewitt-Sperry Automatic Airplane. This development also inspired the development of the Kettering Bug by Charles Kettering from Dayton, Ohio. This was initially meant as an uncrewed plane that would carry an explosive payload to a predetermined target.

The first scaled remote piloted vehicle was developed by film star and model-airplane enthusiast Reginald Denny in 1935. More emerged during World War II – used both to train antiaircraft gunners and to fly attack missions. Nazi Germany produced and used various UAV aircraft during the war. Jet engines entered service after World War II in vehicles such as the Australian GAF Jindivik, and Teledyne Ryan Firebee I of 1951, while companies like Beechcraft offered their Model 1001 for the U.S. Navy in 1955. Nevertheless, they were little more than remote-controlled airplanes until the Vietnam War.In 1959, the U.S. Air Force, concerned about losing pilots over hostile territory, began planning for the use of uncrewed aircraft. Planning intensified after the Soviet Union shot down a U-2 in 1960. Within days, a highly classified UAV program started under the code name of "Red Wagon".

The August 1964 clash in the Tonkin Gulf between naval units of the U.S. and North Vietnamese Navy initiated America's highly classified UAVs into their first combat missions of the Vietnam War. During the War of Attrition (1967–1970) the first

tactical UAVs installed with reconnaissance cameras were first tested by the Israeli intelligence, successfully bringing photos from across the Suez Canal. This was the first time that tactical UAVs, which could be launched and landed on any short runway, were developed and tested in battle.

Figure 1.2: Quadcopter

In the 1973 Yom Kippur War, Israel used UAVs as decoys to spur opposing forces into wasting expensive anti-aircraft missiles. After the 1973 Yom Kippur war, a few key people from the team that developed this early UAV joined a small startup company that aimed to develop UAVs into a commercial product, eventually purchased by Tadiran and leading to the development of the first Israeli UAV. In 1973, the U.S. military officially confirmed that they had been using UAVs in Southeast Asia (Vietnam). Over 5,000 U.S. airmen had been killed and over 1,000 more were missing or captured. During the 1973 Yom Kippur War, Soviet-supplied surface-to-air missile batteries in Egypt and Syria caused heavy damage to Israeli fighter jets. As a result, Israel developed the first UAV with real-time surveillance.

The images and radar decoys provided by these UAVs helped Israel to completely neutralize the Syrian air defenses at the start of the 1982 Lebanon War, resulting in no

pilots downed. The first time UAVs were used as proof-of-concept of super-agility post-stall controlled flight in combat-flight simulations involved tailless, stealth technology-based, three-dimensional thrust vectoring flight control, jet-steering UAVs in Israel in 1987. With the maturing and miniaturization of applicable technologies in the 1980s and 1990s, interest in UAVs grew within the higher echelons of the U.S. military.

In the 1990s, the U.S. DoD gave a contract to AAI Corporation along with Israeli company Malat. Many of these UAVs saw service in the 1991 Gulf War. UAVs demonstrated the possibility of cheaper, more capable fighting machines, deployable without risk to aircrews. Initial generations primarily involved surveillance aircraft, but some carried armaments, such as the General Atomics MQ-1 Predator, that launched AGM-114 Hellfire air-to-ground missiles.

Figure 1.3: A General Atomics MQ-9 Reaper, a hunter-killer surveillance UAV

1.2 Classifications:

UAVs typically fall into one of six functional categories:

1. Target and decoy
2. Reconnaissance
3. Combat
4. Logistics

5. Research and Development
6. Civil and Commercial UAVs

Vehicles can be categorized in terms of range/altitude. The following has been advanced as relevant at industry events such as ParcAberporth Unmanned Systems forum:

- Close 5,000 ft (1,500 m) altitude, up to 10 km range
- Tactical 18,000 ft (5,500 m) altitude, about 160 km range
- MALE (medium altitude, long endurance) up to 30,000 ft (9,000 m) and range over 200 km
- HALE (high altitude, long endurance) over 30,000 ft (9,100 m) and indefinite range
- CIS Lunar Earth-Moon transfer
- Computer Assisted Carrier Guidance System (CACGS) for UAVs

Drones can be classified on a different basis – say based on usage like Drones for Photography, Drones for aerial Mapping, Drones for Surveillance etc. However, the best classification of Drones can be made on the basis of aerial platforms. Based on the type of aerial platform used, there are 4 major types of drones.

1. Multi Rotor Drones
2. Fixed Wing Drones
3. Single Rotor Helicopter
4. Fixed Wing Hybrid VTOL

1.3 Components of an UAV:

Crewed and uncrewed aircraft of the same type generally have recognizably similar physical components. The main exceptions are the cockpit and environmental control system or life support systems. Some UAVs carry payloads (such as a camera) that weigh considerably less than an adult human, and as a result can be considerably smaller. Though they carry heavy payloads, weaponized military UAVs are lighter than their crewed counterparts with comparable armaments. Small civilian UAVs have no lifecritical systems, and can thus be built out of lighter but less sturdy materials and shapes, and can use less robustly tested electronic control systems.

For small UAVs, the quadcopter design has become popular, though this layout is rarely used for crewed aircraft. Miniaturization means that less powerful propulsion technologies can be used that are not feasible for crewed aircraft, such as small electric motors and batteries. Control systems for UAVs are often different than crewed craft. For remote human control, a camera and video link almost always replace the cockpit windows; radio transmitted digital commands replace physical cockpit controls.

A drone or UAV consists of the following essential parts:

1. Frame
2. Motors
3. ESC (electronic speed controller)
4. Propeller
5. Battery
6. Flight Controller
7. RC Receiver

Although slotted design has been implemented for several other applications, none has been developed for low Reynolds number small scale UAV propeller. Thus, this study aims to provide an extensive research on novel slotted designs for small scale propeller blade operating at low Reynolds number, typically less than 100,000. The Reynolds number is measured based on the velocity and chord at 75% span blade station. The objective of this work is to design and study the performance of slotted trailing edge propeller blade operating with Reynolds number less than 100,000. The flow simulations are performed through three-dimensional computational fluid dynamic software (FLUENT) to determine the thrust coefficient, power coefficient and overall efficiency measured in advancing flow conditions.

The analyses were done with both experimental and numerical, in which the experimental data collected are used to validate numerical data. The result shows that the slotted blade design manage to improve the overall performance of the blade, compared to straight and tubercle design. In addition, the result shows that slotted design performed better at low wind speed condition. The size and shape of the propellers used vary just as much as the type of UAV flown. These UAV's are fairly inexpensive and use small motors and propellers with diameters less than 10 in. to provide thrust.

Many of the UAV propellers are operates at higher power consumption. For increasing propeller performance thrust is an important factor while analyzing the

performance of UAV. In order to increase the performance of these propeller we create a corrugated surface in leading edge of a propeller. A corrugated surface of a propeller increases the performance of a UAV with low power consumption. The main objective of our project is to reduce the power consumption of working propeller and produce high thrust and efficiency of UAV while flying. From the development of corrugations in the leading edge we minimize the power consumption and energy losses.

The propeller and propulsion system configuration present losses due to interference with the multi-rotor arms and mutual interference between propellers. In this we are focusses on the effects of propeller configuration on the propulsion system efficiency of the UAV's. The testing choices that are often made during the process of a UAV discussed in this paper, and investigated by a set of experiments.

The influence of shape and thickness of the propeller arm is discussed as a part of our experiment. The various performances are experimented with different parameters and found a small influence on the performance of the UAV. Finally, the mutual influence of propellers in coaxial and overlapping setups is presented. The propeller characteristics obtained from the static tests are used for estimation of UAV performance. These characteristics are presented in terms of certain parameters.

The propeller performance is expressed using non-dimensional coefficients like power coefficient, thrust coefficient, torque coefficient, advance ratio and efficiency of the propeller. The overall propeller thrust, propeller efficiency, rpm and torque will be obtained by integrating the individual element performance from root to tip. The recent measurements of corrugated surface propeller is effective than older model propeller in aerodynamic performances of an UAV's and other applications.

1.4 SUMMARY:

From this chapter we conclude that the performance or uav propeller is differd with the flow pattern. The propeller of an uav will difine the performance of an uav.

CHAPTER 2
LITERATURE REVIEW

2.1 Propeller Aerodynamic Analysis:

A propeller system with increased propulsive thrust, with a sufficiently high level of aerodynamic efficiency for a selected radio-controlled aircraft model. All these improvements to the design of the propeller will be achieved by means of a thorough analysis of the effects of varying the different elements and their geometries, together with experimentation of different sizes and types of propellers. If changes were to be made to the propeller systems to such an extent whereby its propulsive thrust can be further improved for low speed propeller aircrafts, in addition to its already known advantage of being fuel efficient at these low speeds, large costs can be saved, in the manufacturing of the propulsion system itself, on its maintenance, and also on running the flights of the aircrafts especially in a world of soaring fuel prices and ever increasing material costs, as a result or mere consequence of exploiting the earth's natural resources near its limited capacity.

The focus of this report is mainly to analyse and design a propeller system with increased propulsive thrust, without too much of a significant loss in efficiency, for a selected radio-controlled aircraft model. With the known details of the radio-controlled aircraft, a propeller will be designed for maximum performance under optimum conditions. Propeller efficiency, thrust and torque produced will be the primary guidelines along which the propeller design will be achieved.

The main tools being used for the design of the propeller and its dimensions are softwares such as 'Javafoil', 'JavaProp', 'X-foil' and 'GUI Software'. Hand calculations and analytical methods are then carried out to verify the results obtained from the softwares, before an actual propeller is printed from the new "Best" propeller design.The propellers are scanned using a prototype model and further developed by CAD drawing to obtain the geometry of a propeller. The values of thrust, torque and propeller efficiency were measured using GUI software. With that results the propeller is designed by manipulating each individual variables that makes up the geometry. The performance of both propellers are compared using GUI Software again, and then verified with Excel Spreadsheet calculations as well thrust measurement experiments.

The software and analytical thrust values are both within 10% range of the experimental value. However, the software figures for tend to be slightly lower than the experimental, whereas the analytical figures tend to be slightly higher. The torque figures have quite a significant difference between the software and analytical methods, being closer to 20%. This may be attributed to the fact that no comparison is made to an experimental value for torque, which otherwise most likely fall in between the software and analytical values and would make the percentage difference closer to those of the thrust produced, if not similar.

2.2 Review on Tubercles Design:

The design of propellers in aeronautics is still earning high interest. This has led to the application of biomimetic for improving aerodynamic performance. One such design is the usage of tubercles in either leading or trailing edge of airfoils. So the usage of tubercles has so far been in the design of wing or wind-turbines. Recent studies have aimed to study tubercles for the design of a propeller. The studies have so far gained reputations in improving the aerodynamic performance on a few but not all of the airfoil shapes. Similar results have been identified for propeller designs with improvement in thrust at low torque. We have so far led research works on developing new propeller designs with the aim to improve the thrust and torque performance of propeller. Tubercles are sinusoidal wavy formations on the leading edge (LE) that takes the form throughout the surface from leading to trailing edge (TE).

The implementation of tubercles on modern airfoil surfaces originated from the works of Fish humpback whales are found to provide improved aerodynamics with reduced drag while diving and catching prey. The tubercle design has so far been adapted to many but not limited to design of aircraft, marine propeller as well as wind turbine blades.The studies on tubercles so far have been on non-thrust generating designs of fixed aircraft wing and wind turbine and very few studies exist that have been implemented directly on wither aircraft or marine propellers the non-thrust generating platform try to improve lift and stall angle whereas propellers with tubercles have been studied to improve thrust generation.

Tubercles are implemented on LE of the airfoil. The wavelength, amplitude, airfoil, propeller diameter and blade number are fixed for a single design. The analysis is performed numerically in CFD for different advance ratios. The amount of performance in

thrust and torque and aerodynamic efficiency improvements are predicted and compared with a baseline propeller. The sizes of the oblate spheroid are varied as well as the spacing between them and tested for 9 different cases in total. The widths are assumed to be 5, 6.25 and 8 percent of propeller radius. The tubercle intervals are assumed to be 7.14, 8.33, and 10 percent of the effective propeller radius. The height of the spheroid tubercle is assumed to be 2/3 of widths. All the 9 cases were tested for similar Reynolds number (RN) of 5x104. The model with tubercles is assumed to be similar to that of the humpback whale flipper's cross-section resembling a NACA 634-021 airfoil. Both models are identical with one a scaled up version of the other and having similar NACA 0021 cross-sections. The models are compared to a straight-edged model of similar sizes. The study was performed for flow conditions of 1.2x105 and 1.5x106 RN.

The design of aircraft wing or turbine blades, the maximum lift co-efficient (CLmax) and CD achieved in simulation or experiments is provided. The performance of NACA 634-021 airfoil sections. The results of the studies indicate positive maximum increment of CL of 4.8% and 25% respectively compared to baseline. Similarly, the CD has 10.9% and 20% decrement were obtained for RN of 5x104. The performance of NACA 0020 CLmax of 0.93 and 0.88 is achieved for scalloped and smooth flipper and the AOA 12º the models have to develop higher CD at 34% and 69%. The performance of NACA 0014 airfoil RN 1.2x10 Both CL and CD have shown a large decrement compared to baseline. A pressure co-efficient (CP) of 0.39 is achieved marginally higher over straight edged.

The NACA 0020 and NACA 0021 sectional models, the lift and drag performance are found to be inferior compared to baseline straight-edged models. Only for NACA 634-021 airfoil sectional designs, a relatively higher lift and lower drag values have been achieved. This does not preclude the fact that for a propeller, the results showed only a marginal change in CT over baseline in all test cases. The results primarily present a not-so-highly optimistic case for tubercled propellers.

2.3 Performance Data at Low Reynolds Numbers:

The propeller performance for full-scale airplanes has been well documented since the pioneering days of aviation, data on propellers at low Reynolds numbers has been scarce. Many UAVs use propellers that must operate in the low Reynolds number range of

50,000 to 100,000 based on the propeller chord at the 75% propeller-blade station. Tests were performed at the University of Illinois at Urbana-Champaign (UIUC) to quantify the propeller efficiency at these conditions. During the tests, the propeller speed (RPM) was fixed while changing the wind-tunnel speed to sweep over a range of advance ratios until reaching the windmill state (zero thrust).

The experimental setup for this research covers six various sections and the measurements were conducted separately for each parameters.

1. Thrust and Torque Measurements
2. Propeller Speed Measurement
3. Freestream Flow Speed Measurement
4. Motor, Speed Controller and Propellers

From the above measurements all signals were acquired using a National Instruments NI PCI-6031E 16-bit analog-to-digital data acquisition board driven by custom software developed using Lab view, which is a C-based software suite from National Instruments, for creating Graphical User Interfaces (GUIs). The propeller speed measurement required a high data acquisition rate to ensure that the signal from the photo reflector was accurately recorded. Due to limitations on the data acquisition board, this prohibited acquiring all of the data simultaneously. Thus, the propeller speed was first acquired at the higher data acquisition rate, then the remaining quantities (thrust, torque, dynamic pressure, atmospheric pressure, and temperature) were acquired simultaneously immediately thereafter at a reduced rate.

The experimental procedure included setting up the experimental hardware and data acquisition system, calibration and calibration checks of the various instruments, and acquiring the performance data. Acquiring the performance data included obtaining the static performance data as well as obtaining the remaining performance data in one of two test modes. The two possible test modes allowed the experimenter to sweep the advance ratio range by varying either the freestream velocity or propeller speed, while holding the other constant.The propellers tested here are limited to non-folding, two-bladed propellers, a wide range of propeller styles were tested nonetheless. The majority of the propellers tested had diameters ranging from 9 in. to 11 in., though a few larger sizes were tested. For this series of tests, all of the propellers were tested without any alterations.

For this research almost 79 propellers were tested and nearly all fit in the 9- to 11-in. diameter range. Thrust and torque were measured over a range of propeller advance ratios for discrete propeller speeds (RPM's) – typically four different values of RPM to examine low Reynolds number effects. Also static thrust was measured over a range of propeller speeds from nominally 1,500 to 7,500 RPM depending on the propeller diameter. The results showed significant Reynolds number effects with degradation in performance with lower.

2.4 Aerodynamic Characterization of Leading Edge Protrusions:

The relatively large tubercles or protruding bumps on the leading edge of the hump- back whale fin create counter-rotating chord wise vortices. At high Reynolds numbers, these vortices have been shown to delay stall with minimal effect on drag. The range of Reynolds numbers that these types of vortices form is unknown, and so an investigation of the potential for an increased envelope of operation for small aircraft propellers was done. Because of the inherent restrictions on propeller chord length and wind speeds due to rotational speed, which in turn limits the Reynolds number, it is unlikely that the type of modification tested in beneficial for small aircraft propellers typical of unmanned aerial vehicles.

Design of Experiments:

1. Propeller Type Selection
2. Propeller Aerodynamic Design
3. Leading Edge Protrusion Size and Spacing

The size of the propeller and a 5.5 inch diameter and 4 inch pitch propeller was chosen, typical of small aircraft. This propeller had a calculated Reynolds number range of 2.9_104 to 5.3_104 with the variation due to the dynamic wind tunnel speed. The simple design used for full scale wood propellers was chosen. The points of each cross section were then imported into a CAD modelling program, and surface modelling was used to construct the propeller. Three sizes and three spacing's were chosen, resulting in nine test propellers.The height was defined as 2/3 the width, similar to the humpback whale tubercle sizing. The ranges of widths were sized at 5, 6.25, and 8 percent of the effective propeller

radius, or distance from root to tip. The spacing's between protrusions were defined as 7.14, 8.33, and 10 percent of the effective propeller radius, which was 2.5 inches.

The first was efficiency versus advance ratio, which gave insight into the efficiency effects over a wide range of angles of attack represented by the advance ratio. The second was coefficient of thrust versus advance ratio, which gave insight into the thrust effects over a wide range of angles of attack. This induced a small change in the Reynolds number which changed the 8,000 RPM case from 2.9×104 to 3.0×104 and changed the 14,000 RPM case from 4.9×104 to 5.3×104. The record data points consisting of 10 seconds of raw sensor voltages at 400 hertz. To hold the propeller rotational speed (n) constant, a 10 bit micro controller running a PID (proportional-integral-derivative) control algorithm. The result was a constant RPM with a 5 second or less response regardless of load until the maximum system capacity.

The base propeller tested, it has been the leading edge protrusions of the size, spacing, and type in this only contributed to degraded performance. In the case of the small protrusion size and slowest RPM, there were negligible negative effects with little or no positive effects at any of the advance ratios tested. It is possible that testing at higher Reynolds numbers will produce positive results. Where there is an increased chord length or velocity due to rotation, such as a larger aircraft propeller, may see positive results. Larger propellers, or create a validated CFD model and experiment with varying propeller sizes and leading edge geometries. Alternate geometry with the same propeller size and operating conditions may also yield different results.

2.5 SUMMARY:

From this literature survey we conclud that the performance of curregauted propeller in the low renolds number will create high thrust over the surface of the propellers. The analysis of propeller performance in static propeller testing is done based on the survey.

CHAPTER 3

METHODOLOGY

The theory behind this setup, which was experimentally verified, is that the airflow upstream of the propeller is slower than the airflow downstream. The airflow around the propeller has a cone shape. The area of the air affected upstream of the propeller is larger and, due to the conservation of mass, it is also slower. Since drag losses are proportional to the square of the velocity, an obstacle upstream will has a smaller effect on the thrust than an obstacle downstream. The air moving slower causes less drag losses due to the testing equipment, which is why we recommend testing in the configuration of the image above. Testing with the thrust in the other direction can create results 3-20% different due to the airflow interaction with the fixture. In the configuration presented in the image above, the thrust will be positive by default. You can always reverse the reading by activating the reverse thrust checkbox of our software in the "Utilities" tab if you prefer not to have to do that operation in your spreadsheet editor after. Note that your quadcopter arm or airframe will also have an impact on the thrust in flight.

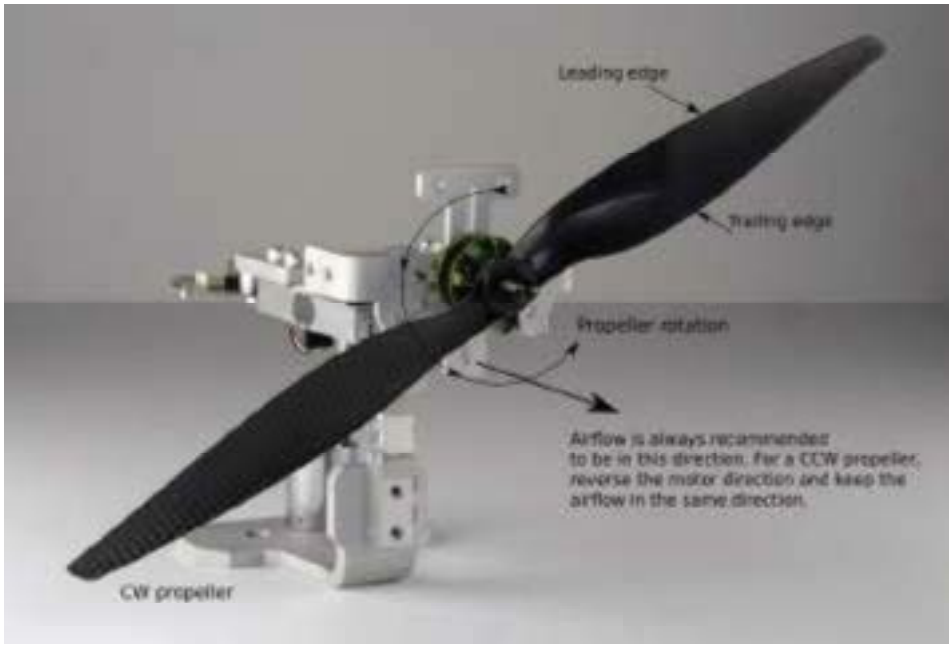

Figure 3.1: Static propeller test

When testing in a wind tunnel, you also have to run a test with the propeller removed from the test fixture to characterize the drag of the measuring instrument. Most of the studies on tubercles so far have been on non-thrust generating designs of fixed aircraft wing and wind turbine and very few studies exist that have been implemented directly on wither aircraft or drone propellers. Studies on non-thrust generating platform try to improve lift and stall angle whereas propellers with tubercles have been studied to improve thrust generation .To hold the propeller rotational speed (n) constant, a 10 bit micro controller running a PID (proportional-integral-derivative) control algorithm was used.

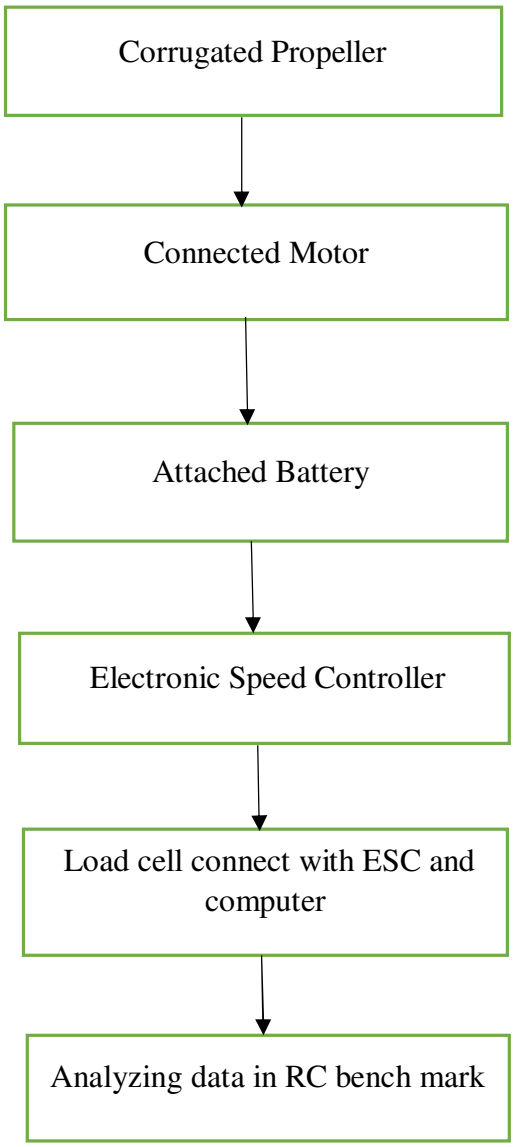

Figure 3.2 Flow chart for static propeller test

The PID algorithm was defined by the open source PID library from Adriano. The micro-controller was set up to measure the motor RPM from the voltage pulses coming from the three leads of the brushless motor using an Eagle tree rpm sensor. Pulses were counted, polled, and reset at a set interval. Using a strobe tachometer, the relation between the rpm and the number of pulses per interval was found to be linear and the relation was implemented into the PID controller. The proportional, derivatives, and integral gains were chosen to give an adequate response time without oscillation. The result was a constant RPM with a 5 second or less response regardless of load until the maximum system capacity.

3.1 Static test:

Static testing is a software testing method that involves examination of the program's code and its associated documentation but does not require the program be executed. It is primarily checking of the code and/or manually reviewing the code or document to find errors.

This type of testing used to find

Motor efficiency

Thrust efficiency

Power efficiency

Propeller vibration

3.1.1 Motor efficiency:

Electric motor efficiency is the ratio between power output (mechanical) and power input (electrical). Mechanical power output is calculated based on the torque and speed required (i.e. power required to move the object attached to the motor), and electrical power input is calculated based on voltage and current supplied to the motor. Mechanical power output is always lower than the electrical power input, as energy is lost during conversion (electrical to mechanical) in various forms, such as heat and friction. Design of an electric motor aims to minimize these losses to improve efficiency.

$$\text{Motor efficiency} = \frac{output\ power}{input\ power} \times 100$$

The brushless motor and system used a 200-W motor with ratio that was capable of driving the propeller to a maximum speed of 7,500 RPM. For simplicity in the laboratory, a variable voltage switch mode power supply, made by BK Precision, is used to power the motor. The model used, the BK1692, can be set to an output voltage of 3 V to 15 V with a maximum current of 40 A. Given the brushless motor designed to work with a speed controller, a method was needed to send the appropriate signal to the speed controller. To set the rotational speed, a device called the Servo EF, made by Vexa Control, was used. This device is designed to be used for testing R/C servos by allowing the operator to adjust the pulse-width of the signal being sent to the server.

3.1.2 Thrust efficiency:

It is defined as the ratio of useful power output to the rate of energy input. For flight, propulsive efficiency is expressed as: thrust flight speed. Kinetic energy increase of fluid.The thrust produced by a right-handed propeller. The thrust measurement was obtained outside the static test through a pendulum T-shaped structure that pivoted about two flexural pivots while being constrained by a load cell outside of the stand. The Interface model SM-10 load cell was used, having a maximum capacity of 2 kg. To ensure that the Freestream flow did not produce a drag force on the beam located the stand, the torque produced by the propeller was measured using the reaction torque transducers made by Transducer Techniques.

3.1.3 Power efficiency:

Power efficiency is defined as the ratio of the output power divided by the input power: $\eta = 100\% \cdot P_{out} / P_{in}$. η is the efficiency in percent (%). P_{in} is the input power consumption in watts (W). P_{out} is the output power or actual work in watts (W).

$$\eta_p = \frac{P_{out}}{P_{in}} = \frac{T \times V}{E \times I}$$

Where:

η_p = Propulsive efficiency

T = Thrust

V = Flight velocity (knots)

a = Velocity increment at the propeller disc (knots)

To measure the propeller rotation speed, to count the number of revolutions the output shaft made in a fixed time interval. Which has a transistor output and allows the sensor to be placed up to 0.5 in. From the reflective surface. When combined with a simple circuit of resistors and a 9-V battery, the output voltage was near 2 V when aimed at a reflective surface and near 0 V when aimed at a non-reflective surface. The circuit had a response time around 5 μsec. The output voltages and response time of the circuit proved to be more than sufficient for measuring the rotational speed of the propellers, which never exceeded 7,000 RPM in these tests.

3.1.4 Propeller Torque:

Torque effect is the influence of engine torque on aircraft movement and control. It is generally exhibited as a left turning tendency in piston single engine propeller driven aircraft. The torque produced by the propeller was measured using the reaction torque transducers made by Transducer Techniques. These devices are simply force transducers housed and calibrated so that, when placed appropriately, a torque can be measured. The rig was designed with the torque transducer placed between the motor housing and support arm of the thrust mechanism, as is shown in one of two torque transducers was used depending on the expected maximum torque.

3.2 SUMMARY:

Static propeller test rig is mainly used to find propeller's thrust, torque, efficiuency and other characteristics with various rotational speeds. In this setup we simply change the rpm of the propeller to find the results.

CHAPTER 4
MATERIAL USED AND CHARACTERISATION

The materials used in our project are explain in detail in this chapter. The selection of various materials are listed and its characteristics are listed in this chapter.

4.1 Brushless motor:

A brushless DC electric motor (BLDC motor or BL motor), also known as electronically commutated motor (ECM or EC motor) and synchronous DC motors, are synchronous motors powered by direct current (DC) electricity via an inverter or switching power supply which produces electricity in the form of alternating current (AC) to drive each phase of the motor via a closed loop controller. The controller provides pulses of current to the motor windings that control the speed and torque of the motor. The construction of a brushless motor system is typically similar to a permanent magnet synchronous motor (PMSM), but can also be a switched reluctance motor, or an induction (asynchronous) motor.

The advantages of a brushless motor over brushed motors are high power-to-weight ratio, high speed, electronic control, and low maintenance. Brushless motors find applications in such places as computer peripherals (disk drives, printers), hand-held power tools, and vehicles ranging from model aircraft to automobiles.

Figure 4.1: Brushless motor

The simplest type of motor is the brushed DC motor. In this type of motor, electrical current is passed through coils that are arranged within a fixed magnetic field. The current generates magnetic fields in the coils; this causes the coil assembly to rotate, as each coil is pushed away from the like pole and pulled toward the unlike pole of the fixed field. To maintain rotation, it is necessary to continually reverse the current so that coil polarities will continually flip, causing the coils to continue "chasing" the unlike fixed poles. Power to the coils is supplied through fixed conductive brushes that make contact with a rotating commutator; it is the rotation of the commutator that causes the reversal of the current through the coils. The commutator and brushes are the key components distinguishing the brushed DC motor from other motor types. Illustrates the general principle of the brushed motor.

4.2 ESC:

The Drone Electronic Speed Controller (ESC) on a drone is a hard-working, powerful component. The ESC connects the flight controller and the motor. Given that each brushless motor requires an ESC, a quadcopter will require 4 ESCs. The ESC takes the signal from the flight controller and power from the battery and makes the brushless motor spin. Although it sounds simple, it is anything but! Although some micro drones use brushed motors, the mini quads used in racing and freestyle rely on brushless motors. Like the name implies, a brushless motor lacks contacts, or "brushes" inside the motor. The brush acts as what is called a commutator, which uses physical contact of the motor's windings to spin the motor. Because they lack the brush, brushless motors use a different way to turn direct current (DC), the one-way flow of electrons, into a type of alternating current (AC).

An electronic speed control follows a speed reference signal (derived from a throttle lever, joystick, or other manual input) and varies the switching rate of a network of field effect transistors (FETs) by adjusting the duty cycle or switching frequency of the transistors, the speed of the motor is changed. The rapid switching of the transistors is what causes the motor itself to emit its characteristic high-pitched whine, especially noticeable at lower speeds.

Figure 4.2: ESC 30 amp

Different types of speed controls are required for brushed DC motors and brushless DC motors. A brushed motor can have its speed controlled by varying the voltage on its armature. (Industrially, motors with electromagnet field windings instead of permanent magnets can also have their speed controlled by adjusting the strength of the motor field current.) A brushless motor requires a different operating principle. The speed of the motor is varied by adjusting the timing of pulses of current delivered to the several windings of the motor. Brushless ESC systems basically create three-phase AC power, like a VFD variable frequency drive, to run brushless motors. Brushless motors are popular with radio controlled airplane hobbyists because of their efficiency, power, longevity and light weight in comparison to traditional brushed motors. Brushless DC motor controllers are much more complicated than brushed motor controllers.

The correct phase varies with the motor rotation, which is to be taken into account by the ESC: Usually, back EMF from the motor is used to detect this rotation, but variations exist that use magnetic (Hall effect) or optical detectors. Computer-programmable speed controls generally have user-specified options which allow setting low voltage cut-off limits, timing, acceleration, braking and direction of rotation. Reversing the motor's direction may also be accomplished by switching any two of the three leads from the ESC to the motor.

4.3 Gas and glow propellers:

Gas and glow props are designed to withstand the power surges of an internal combustion engine, and are stronger, heavier, and designed for (usually) larger diameter shaft mounts. Electric props are lighter, and props designated for Slow Fly use tend to have wider blades for greater efficiency at lower RPM APC propellers are made from composite materials using long glass fibers or long carbon fibers with a Nylon matrix. Three types of APC propellers were tested, namely the Slow Flyer, Sport, and Thin Electric propellers. Both the Slow Flyer and Thin Electric propellers are designed to be used solely with electric motors. The Sport propellers are designed to handle the increased torque produced by gas powered engines. The airfoil profiles on the Slow Flyer propellers are quite thin with a sharp leading edge, where the remaining two have thicker airfoil sections with rounded leading edges. All of the APC propellers show some variation in the performance curves that is consistent with the overall trends. The Slow Flyers show the least variation in efficiency and the differences are larger near peak.

Figure 4.3: Gas and glow propeller

APC preserves a close rapport with the competitive aviation community to benefit from the technical interchange that is so important to improving designs. There is continuous evolution in aircraft design and engine performance. Consequently, propeller designs must continuously evolve to keep pace with changing technologies. APC excels at providing the model aviation community the right propellers for a wide range of applications.

The molding compound used in APC propellers is manufactured using a pultrusion process. This method causes the fiberglass "fibers" to be oriented axially in 1/2 inch long pellets. This long fiber compound allows a higher fiber (60%) to resin (nylon binder) density than short or chopped fiber compounds. Reground material is never used for APC propellers. Viscous (skinning) effects during injection molding cause these long fibers to remain dominantly oriented in the propeller span-wise axis.

4.4 Load cell:

A load cell is a type of transducer, specifically a force transducer. It converts a force such as tension, compression, pressure, or torque into an electrical signal that can be measured and standardized. As the force applied to the load cell increases, the electrical signal changes proportionally.

Figure 4.4: 2kg load cell

A strain gauge is constructed of very fine wire, or foil, set up in a grid pattern and attached to a flexible backing. When the shape of the strain gauge is altered, a change in its electrical resistance occurs. The wire or foil in the strain gauge is arranged in a way that, when force is applied in one direction, a linear change in resistance results. Tension force stretches a strain gauge, causing it to get thinner and longer, resulting in an increase in resistance. Compression force does the opposite. The strain gauge compresses, becomes thicker and shorter, and resistance decreases. The strain gauge is attached to a flexible backing enabling it to be easily applied to a load cell, mirroring the minute changes to be measured. Strain gauge load cells are the kind most often found in industrial settings.

It is ideal as it is highly accurate, versatile, and cost-effective. Structurally, a load cell has a metal body to which strain gauges have been secured. The body is usually made of aluminium, alloy steel, or stainless steel which makes it very sturdy but also minimally elastic. This elasticity gives rise to the term "spring element", referring to the body of the load cell. When force is exerted on the load cell, the spring element is slightly deformed, and unless overloaded, always returns to its original shape. As the spring element deforms, the strain gauges also change shape. The resulting alteration to the resistance in the strain gauges can be measured as voltage. The change in voltage is proportional to the amount of force applied to the cell, thus the amount of force can be calculated from the load cell's output.

4.5 Battery:

A lithium polymer battery, or more correctly lithium-ion polymer battery (abbreviated as LiPo, LIP, Li-poly, lithium-poly and others), is a rechargeable battery of lithium-ion technology using a polymer electrolyte instead of a liquid electrolyte. High conductivity semisolid (gel) polymers form this electrolyte. These batteries provide higher specific energy than other lithium battery types and are used in applications where weight is a critical feature, like mobile devices and radio-controlled aircraft. Just as with other lithium-ion cells, LiPos work on the principle of intercalation and de-intercalation of lithium ions from a positive electrode material and a negative electrode material, with the liquid electrolyte providing a conductive medium. To prevent the electrodes from touching each other directly, a microporous separator is in between which allows only the ions and not the electrode particles to migrate from one side to the other.

The lithium battery packs used to power quadcopters have two common chemistries: Lithium polymer (LiPO) and lithium polymer high voltage (LiHV). The primary difference between the two is that a LiPO cell has a fully charged voltage of 4.2V compared to a LiHV cell which has a voltage of 4.35V at full charge. A LiPO has a resting or nominal voltage of 3.7V versus a LiHV which has a storage voltage of 3.8V. In regards to the performance of the two packs, a LiHV battery will initially provide more power but abruptly drops in voltage when discharged whereas a LiPO has a more linear discharge making it easier to qualitatively gauge the remaining flight time.

Figure 4.5: lithium polymer Battery

LiPO packs are the most commonly used across all sizes of quadcopters however LiHV packs are quite popular for use on "Tiny Whoop" micro drones because the extra voltage moderately improves the quadcopters performance. Battery voltage is the potential energy difference between the positive and negative terminals. A higher FPV Drone Battery voltage allows the pack to provide more power to the quadcopter without increasing the current or amp draw. A standard lithium polymer cell has a nominal (storage) voltage of 3.7V hence to increase the power that a single LiPO pack can deliver, these cells are grouped together in series (meaning the ground/negative lead from the first cell is connected to the positive lead of the next cell, forming a chain of individual cells) to increase the overall battery pack voltage.

LiPO packs are commonly sold in 1S, 2S, 3S, 4S, 5S or 6S configurations where the digit followed by the 'S' stands for number of cells in that specific pack. The more cells that are grouped together, the more voltage the overall battery pack will have. The battery pack voltage is important as it impacts the maximum motor speed of a quadcopter. This is explained further here [insert hyperlink to the article on motors/ section on KV] but simply, more battery voltage allows the motors to spin with greater speed (RPM). For this reason, 4S LiPO's are the most commonly used for racing quadcopters as they provide a balance between speed and weight.

It is important to note that the quadcopter applications listed in the following table are only typical examples from the many different battery-quadcopter combinations in existence. Exotic setups such as 5S 150mm racing quadcopters or 2S micro brushed quadcopters do exist however they are just quite uncommon.

4.6 Static propeller stand:

The theory behind this setup, which was experimentally verified, is that the airflow upstream of the propeller is slower than the airflow downstream. The airflow around the propeller has a cone shape. The area of the air affected upstream of the propeller is larger and, due to the conservation of mass, it is also slower. Since drag losses are proportional to the square of the velocity, an obstacle upstream will has a smaller effect on the thrust than an obstacle downstream. The air moving slower causes less drag losses due to the testing equipment, which is why we recommend testing in the configuration of the image above. Testing with the thrust in the other direction can create results 3-20% different due to the airflow interaction with the fixture.

In the configuration presented in the image above, the thrust will be positive by default. You can always reverse the reading by activating the reverse thrust checkbox of our software in the "Utilities" tab if you prefer not to have to do that operation in your spreadsheet editor after. Note that your quadcopter arm or airframe will also have an impact on the thrust in flight. When testing in a wind tunnel, you also have to run a test with the propeller removed from the test fixture to characterize the drag of the measuring instrument, which you will subtract from your test results.

Figure 4.6: Static propeller stand

4.7 SUMMARY:

The materials discussed in this chapter are used in our projet for their better experience and working profiles besd on the characteristics. The major material in this chapter is static propeller stand that mainly used to find the results.

CHAPTER 5

RESULT AND DISCUSSION

The experiments have been performed for investigating the static performance of the gas and glow (APC brand) propeller with and without heading edge modifications. The performance parameters such as thrust, torque and propeller efficiency have been measured in the propeller test rig for different type propellers with constant diameter and varying pitch vice versa. By inspiring the maneuvers done by humpback whales, the leading edge flippers like structures are incorporated in the hub or in the tip to study its capability in increasing thrust and propeller efficiency without increasing the torque. Illustrates the variation of thrust, torque and propeller efficiency with rotated speed of the propeller with and without leading edge modifications with increase in rotational speed of the propeller, the thrust, and torque increases for all the propeller combinations studied here. At the same time, the propeller efficiency initially shows a drastic increase for increase in rotational speed is in line with the similar variation reported in the literatures.

By introducing a leading edge flippers near the tip of the propeller the thrust and propeller efficiency shows lower magnitude but torque does not show any change in magnitude than the propeller without any leading edge flipper. At the same time, the thrust and propeller efficiency has higher magnitude without increasing the torque required for running the propeller while introducing flippers near the hub of the propellers. However, while increasing the number of flippers near the hub of the propeller, the thrust and propeller efficiency has lower magnitude than the propeller without any leading edge flippers. The increment in performance of the propeller has been mainly attributed to the counter rotating vortices formed due to the leading edge flippers lower the speed near the hub of the propeller are effective in harnessing effect of counter rotating vortices. At the same, the blade speed is very high at the tip which in turn creating instability within counter rotating vortices. This results in reducing the magnitude of the performance parameters. The experimental testing of the propeller performance study proves the performance of the propeller can be increased by introducing leading edge flipper near the hub of the propeller.

5.1 Data and result for 7×4 propeller testing

5.1.1Table: 7×4 propeller testing

S.NO	Acceleration (g)	Torque (nm)	Thrust (kgf)	Voltage (V)	Current (A)	Motor optical speed (RPM)

The increasing number of flippers near the hub of the propeller, the thrust and propeller efficiency has lower magnitude than the propeller without any leading edge flippers. The increment in performance of the propeller has been mainly attributed to the counter rotating vortices formed due to the leading edge flippers lower the speed near the hub of the propeller are effective in harnessing effect of counter rotating vortices. At the same, the blade speed is very high at the tip which in turn creating instability within counter rotating vortices. This results in reducing the magnitude of the performance parameters. The experimental testing of the propeller performance study proves the performance of the propeller can be increased by introducing leading edge flipper near the hub of the propeller.

5.3 SUMMARY:

The results of our propeller test is consolidated in this chapter with various propeller speeds. The performance of propeller like thrust, torque, and efficiency are collected and graphs were ploted based on the result values.

CHAPTER 6
CONCLUSION

The development and validation of a propeller, suitable to test a wide range of low Reynolds number propellers up to a diameter of about 7×4 and 7×9. The surface corrugations in the leading edge of a propeller will increases the performance of an UAV with normal power consumption. Furthermore, the performance of gas and glow propellers was measured over a range of different rotational speeds. It was shown that as the increases of performance with the increase of propeller rpm, the propellers performance is significantly affected by increasing their thrust coefficient and efficiency. While increasing the number of flippers near the hub of the propeller, the thrust and propeller efficiency has lower magnitude than the propeller without any leading edge flippers.

The increment in performance of the propeller has been mainly attributed to the counter rotating vortices formed due to the leading edge flippers lower the speed near the hub of the propeller are effective in harnessing effect of counter rotating vortices. At the same, the blade speed is very high at the tip which in turn creating instability within counter rotating vortices. This results in reducing the magnitude of the performance parameters. The experimental testing of the propeller performance study proves the performance of the propeller can be increased by introducing leading edge flipper near the hub of the propeller.

The tests done in this study operating low Reynolds number. The inherent propeller size and operating conditions in this study gave a Reynolds number of about high, an order of magnitude lower.

The leading edge corrugation in the tests done in this report seem to only contribute to vibration and drag. It is possible that testing at higher Reynolds numbers will produce positive results.

EXPERIMENTAL INVESTIGATION OF PROPELLER EFFICIENCY WITH PROPELLER SURFACE CORRUGATIONS

G.Sasi[1], S.Azhagarasan[2], S.Gowtham Prabhu[3], K.Pavithra[4]

[1] Assistant professor, [2,3,4] Student, Final year B.E, Department of Aeronautical Engineering, Paavai Engineering College, Namakkal

Abstract: The propeller is the primary component of flying vehicles powered by electric motors, internal combustion engines, and turboprops for producing thrust. A propeller thrust is produced in the engine by effective spinning of the propeller through air for cost-effective and environmental friendly flight. Natural flyers like birds as well as aquatic animals like humpback whales effectively use its wings and flippers with its surface features for capturing its prey and escaping from their enemies. As part of this work, corrugations are established in the leading edges or in the suction surfaces of the propeller to modify the flow field prevailing over there. Because of the flow field, the surface corrugations or leading edge corrugations energize the boundary layer in the surfaces of the propeller by counter-rotating vortices which, in turn, delays the separation of the boundary layer from the surface. The performance parameters of the propeller such as thrust, torque, propeller efficiency, power consumption etc., are measured using propeller test rig. Depending on the location of surface or leading corrugations, the variations in the performance of the propeller are investigated for further optimization on the selection of better propeller to the applications of UAVs operating at low Reynolds No.

Introduction: An Unmanned Aerial Vehicles capable of Vertical Take-Off and Landing (VTOL UAVs), are increasingly deployed for various applications such as surveillance, autonomous parcel delivery, oil and gas spill detection and firefighting. The development of Unmanned Aerial Vehicles (UAV) for civil and military applications has increased significantly over the last decade. More industries such as agricultural, educations, communications, and energy sector are becoming more courageous to venture into the utilizations of UAV to carry our various missions. As the advancement of technologies, the implementation of UAV may contribute to increase in productivity as well as reducing the risk, allowing replacement of manned mission [1-3]. This is because UAVs are cost and maintenance friendly. Hence, it is very important to have high-performance UAV design so that it could deliver the mission efficiently.

An unmanned aerial vehicle (UAV) is an aircraft without a human pilot on board and a type of unmanned vehicle. UAVs are a component of an unmanned aircraft system (UAS); which include a UAV, a ground-based controller, and a system of communications between the two. The flight of UAVs may operate with various degrees of autonomy: either under remote control by a human operator or autonomously by onboard computers. Compared to crewed aircraft, UAVs were originally used for missions too "dull, dirty or dangerous" for humans [4-7]. While they originated mostly in

ABSTRACT

The selection of aero-engine that can meet the design specifications of aircraft is the primary step to the overall design program of an aircraft. Global aviation traffic is expected to increase at an annual rate of 5% for the foreseeable future. However, the engine emissions such as CO, CO_2, UHC, and NO_X have greater adverse impact on the earth atmosphere and human health in addition to its performance degradation. Proper design of the aero-engine to the design requirements of the particular aircraft is essential for meeting the highly competitive airline market. Turbojet is an air-breathing engine which works under the basis of Brayton Cycle. The efficiency and thrust produced by the engine depend on the individual performance of the turbojet components such as Intake, Compressor, Combustion Chamber, Turbine, and Propelling Nozzle in addition to its various operating atmospheric conditions. Here, program has been developed to do a conceptual design of the aero-engine and also performance analysis chart will be developed for the aero-engine to meet the design requirements of the aircraft.

CHAPTER – I

INTRODUCTION

Since the introduction of the first operational jet engine, engine development has been on larger engines to meet the increasing demands of thrust , SFC, specific thrust etc., Now a days there are numerous ideas to design an engine to increase the performance but before starting the process we are undergoing the conceptual design to analyse the performance characteristic to check the design satisfies our mission requirements. Conceptual design is the first step of the multiphase process involved in creating a new product. The conceptual design phase is immediately followed by the schematic design phase. In this process we are using multiple input parameter like operating altitude, Mach.No& component efficiency like compressor ratio, turbine inlet temperature and mechanical transmission efficiency. To determine the compressor stagnation properties from compressor pressure ratio, work done on the compressor and isentropic efficiency of compressor and also find the turbine outlet stagnation condition by equating the work done on the compressor with work done by the turbine through mechanical transmission efficiency and turbine inlet temperature. The compressor exit stagnation condition, turbine inlet temperature and stagnation pressure loss in the combustor using to estimation of fuel-air through energy balance analysis. The above condition will then form the basis for the conceptual design of the component. Our motivation is to provide performance analysis data sheet using MATLAB for the various mission requirement which is used to find whether the engine design was efficient or not.

1.1 CLASSIFICATION OF ENGINE

The turbojet is an airbreathing jet engine, typically used in aircraft. It consists of a gas turbine with a propelling nozzle. The gas turbine has an air inlet, a compressor, a combustion chamber, and a turbine (that drives the compressor). The compressed air from the compressor is heated by the fuel in the combustion chamber and then allowed to expand through the turbine. The turbine exhaust is then expanded in the propelling nozzle where it is accelerated to high speed to provide thrust. Two engineers, Frank Whittle in the United Kingdom and Hans von Ohain in Germany, developed the concept independently into practical engines during the late 1930s.

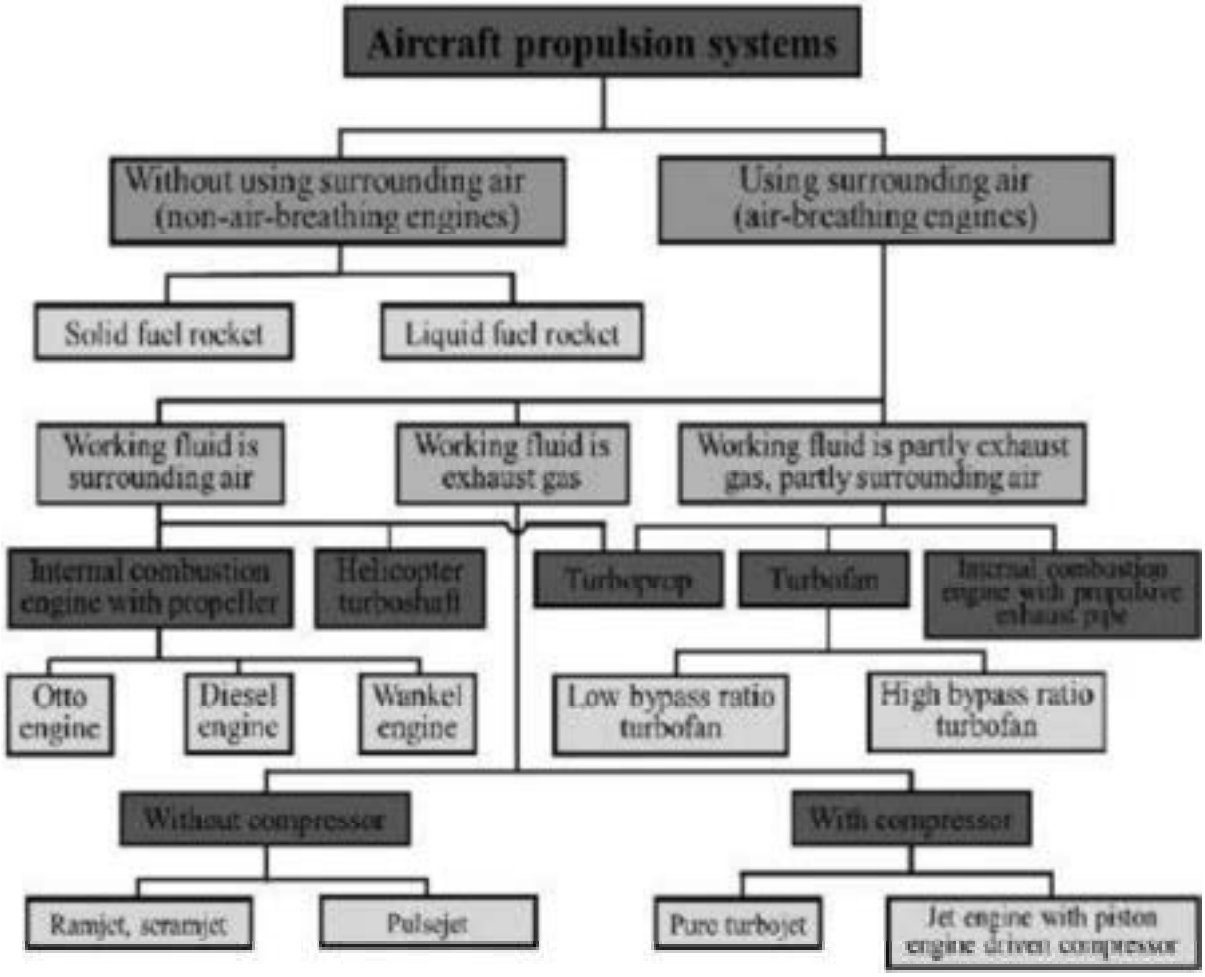

Figure.no: 1.1 Classification of jet engine

The turbojet is an airbreathing jet engine, typically used in aircraft. It consists of a gas turbine with a propelling nozzle. The gas turbine has an air inlet, a compressor, a combustion chamber, and a turbine (that drives the compressor). The compressed air from the compressor is heated by the fuel in the combustion chamber and then allowed to expand through the turbine. The turbine exhaust is then expanded in the propelling nozzle where it is accelerated to high speed to provide thrust. Two engineers, Frank Whittle in the United Kingdom and Hans von Ohain in Germany, developed the concept independently into practical engines during the late 1930s.

While the turbojet was the first form of gas turbine powerplant for aviation, it has largely been replaced in use by other developments of the original concept. In operation, turbojets typically generate thrust by accelerating a relatively smallamount of air to very high supersonic speeds, whereas turbofans accelerate a larger amount of air to lower transonic speeds. Turbojets have been replaced in slower aircraft by turboprops because they have better specific fuel consumption. At medium speeds, where the propeller is no longer efficient, turboprops have

been replaced by turbofans. The turbofan is quieter and has better range-specific fuel consumption than the turbojet. Turbojets can be highly efficient for supersonic aircraft.

Turbojets have poor efficiency at low vehicle speeds, which limits their usefulness in vehicles other than aircraft. Turbojet engines have been used in isolated cases to power vehicles other than aircraft, typically for attempts on land speed records. Where vehicles are 'turbine powered' this is more commonly by use of a turboshaft engine, a development of the gas turbine engine where an additional turbine is used to drive a rotating output shaft. These are common in helicopters and hovercraft. Turbojets were used on Concorde and the longer-range versions of the TU-144 which were required to spend a long period travelling supersonically. Turbojets are still common in medium range cruise missiles, due to their high exhaust speed, small frontal area, and relative simplicity. They are also still used on some supersonic fighters such as the MiG-25, but most spend little time travelling supersonically, and so employ turbofans and use afterburners to raise exhaust speed for supersonic sprints.

1.2 DESIGN

1.2.1 AIR INTAKE

An intake, or tube, is needed in front of the compressor to help direct the incoming air smoothly into the moving compressor blades. Older engines had stationary vanes in front of the moving blades. These vanes also helped to direct the air onto the blades. The air flowing into a turbojet engine is always subsonic, regardless of the speed of the aircraft itself.

The intake has to supply air to the engine with an acceptably small variation in pressure (known as distortion) and having lost as little energy as possible on the way (known as pressure recovery). The ram pressure rise in the intake is the inlet's contribution to the propulsion system's overall pressure ratio and thermal efficiency.

The intake gains prominence at high speeds when it transmits more thrust to the airframe than the engine does. Well-known examples are the Concorde and Lockheed SR-71 Blackbird propulsion systems where the intake and engine contributions to the total powerplant were 63%/8%at Mach 2 and 54%/17%at Mach 3+. Intakes have ranged from "zero-length" on the Pratt & Whitney TF33 installation in the Lockheed C-141 Star lifter, to the twin, 65 feet-long, intakes on the North American XB-70 Valkyrie, each feeding three engines with an intake airflow of about 800 lb/sec.

1.2.2 COMPRESSOR

The compressor is driven by the turbine. It rotates at high speed, adding energy to the airflow and at the same time squeezing (compressing) it into a smaller space. Compressing the air increases its pressure and temperature. The smaller the compressor, the faster it turns. At the large end of the range, the GE-90-115 fan rotates at about 2,500 RPM, while a small helicopter engine compressor rotates around 50,000 RPM.

Turbojets supply bleed air from the compressor to the aircraft for the environmental control system, anti-icing, and fuel tank pressurization, for example. The engine itself needs air at various pressures and flow rates to keep it running. This air comes from the compressor, and without it, the turbines would overheat, the lubricating oil would leak from the bearing cavities, the rotor thrust bearings would skid or be overloaded, and ice would form on the nose cone. The air from the compressor, called secondary air, is used for turbine cooling, bearing cavity sealing, anti-icing, and ensuring that the rotor axial load on its thrust bearing will not wear it out prematurely. Supplying bleed air to the aircraft decreases the efficiency of the engine because it has been compressed, but then does not contribute to producing thrust. Bleed air for aircraft services is no longer needed on the turbofan-powered Boeing 787.

Compressor types used in turbojets were typically axial or centrifugal. Early turbojet compressors had low pressure ratios up to about 5:1. Aerodynamic improvements including splitting the compressor into two separately rotating parts, incorporating variable blade angles for entry guide vanes and stators, and bleeding air from the compressor enabled later turbojets to have overall pressure ratios of 15:1 or more. For comparison, modern civil turbofan engines have overall pressure ratios of 44:1 or more. After leaving the compressor, the air enters the combustion chamber. There are three basic categories of gas turbine engine compressor.

1. Axial compressor
2. Centrifugal compressor
3. Mixed- flow compressor

1.2.2.1 WORKING PRINCIPLE OF COMPRESSOR

The basic working principle of an air compressor is to compress atmospheric air which is the used as per the requirements. In the process, atmospheric air is drawn in through an intake valve; more and more air is pulled inside a limited space mechanically by means of piston, impeller, or vane.

1.2.2.2 AXIAL COMPRESSOR

Axial compressors are used in medium to large thrust gas turbine engines, because the alternative centrifugal units would be too heavy and too large in the cross-sectional area. At smaller sizes, the axial blading at the rear of the compressor losses its robustness and is difficult to manufactured accurately. Consequently, manufacturers tend to replace the rear stages with a centrifugal unit. The compression system is then said to be axial centrifugal. In case of power generation axial compressors are used in turbines which have capacity to generate more than 5MW.

ADVANTAGES :

- The ability to handle large volumes of airflow and a high-pressure ratio.
- Small frontal area for given airflow.

- Straight-through flow, allowing high ram efficiency

DISADVANTAGES:

- More susceptible to foreign object damage.
- Expensive to manufacture.
- Very heavy in comparison to the centrifugal compressor with the same compression ratio.

1.2.2.3 CENTRIFUGAL COMPRESSOR:

At even smaller sizes particularly in turboprop by turboshaft applications, the compression system is either a single centrifugal or has two centrifugal units connected in series (i.e. double- centrifugal).It basically consists of an impeller(rotor), a diffuser(stator), and a compressor manifold. The two main elements are impeller and diffuser. The impeller function is to pick up and accelerate the air outwardly to the diffuser. The double impeller is to two impellers are the duct and ducting arrangements. Double entry types have a smaller diameter, but are usually operated at a higher rotational speed to ensure sufficient airflow. A single-entry impeller permits ensure convenient ducting directly to the impeller eye as opposed to the more complicated ducting necessary to reach the rear side of the double entry type.

ADVANTAGES:

- Light weight.
- High pressure rise per stage.
- Simplicity of manufacture, thus low cost.
- Low weight.

DISADVANTAGES:

- Large frontal area for given airflow.
- More than two stages are not practical, because of losses in turns between stages.

1.2.2.4 MIXED-FLOW COMPRESSOR:

In the future, mixed flow compressor may feature at the small end of the market, particularly in turbofans where the relatively large diameter across the diffuser of a centrifugal compressor is significant disadvantages.

1.2.2.5 STAGED COMPRESSION:

TWO STAGE:

At high overall pressure ratios, the compression system is usually split into two units; a low pressure (LP) compressor mounted on one shaft followed by a high pressure (HP) compressor mounted on the HP shaft and driven by its own (HP) turbine. On civil turbofan the first stage of the LP compressor is often a single stage fan. if the compressor if the HP compressor pressure ratio exceeds about 4.5:1, then the unit will probably have variable geometry(i.e, variable stators)on the first few stages, to meet the surge line on the compressor map more shallow, to accommodate the shallow working line.

THREE STAGES:

On their large civil turbofans, Rolls Royce split the compression system into three: a fan, an intermediate compressor, and HP compressor each unit being driven by its own turbine unit the RB199 military turbofan also has this arrangement.

1.2.3 COMBUSTION CHAMBER

The burning process in the combustor is significantly different from that in a piston engine. In a piston engine, the burning gases are confined to a small volume, and as the fuel burns, the pressure increases. In a turbojet, the air and fuel mixture burn in the combustor and pass through to the turbine in a continuous flowing process with no pressure build-up. Instead, a small pressure loss occurs in the combustor.

The fuel-air mixture can only burn in slow-moving air, so an area of reverse flow is maintained by the fuel nozzles for the approximately stoichiometric burning in the primary zone. Further compressed air is introduced which completes the combustion process and reduces the temperature of the combustion products to a level which the turbine can accept. Less than 25% of the air is typically used for combustion, as an overall lean mixture is required to keep within the turbine temperature limits.

1.2.3.1 CAN

Can combustors are self-contained cylindrical combustion chambers. Each "can" has its own fuel injector, igniter, liner, and casing. The primary air from the compressor is guided into each individual can, where it is decelerated, mixed with fuel, and then ignited. The secondary air also comes from the compressor, where it is fed outside of the liner (inside of which is where the combustion is taking place). The secondary air is then fed, usually through slits in the liner, into the combustion zone to cool the liner via thin film cooling.

In most applications, multiple cans are arranged around the central axis of the engine, and their shared exhaust is fed to the turbine(s). Can type combustors were most widely used in early gas turbine engines, owing to their ease of design and testing (one can test a single can, rather than have to test the whole system). Can type combustors are easy to maintain, as only

a single can needs to be removed, rather than the whole combustion section. Most modern gas turbine

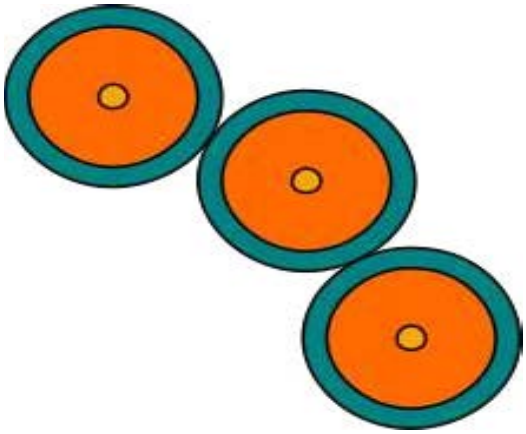

Figure.no: 1.2 Can type combustion chamber

engines (particularly for aircraft applications) do not use can combustors, as they often weigh more than alternatives. Additionally, the pressure drop across the can is generally higher than other combustors (on the order of 7%). Most modern engines that use can combustors are turbo-shafts featuring centrifugal compressors.

1.2.3.2 CANNULAR

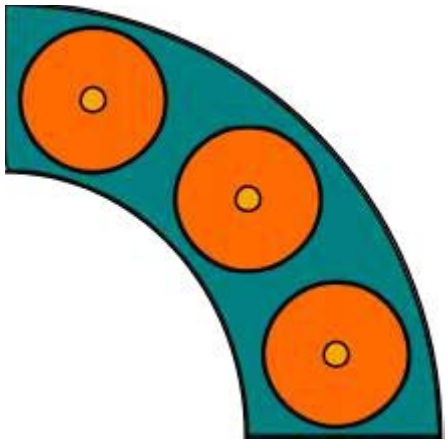

Figure.no: 1.3 Cannular type combustion chamber

Cannular combustor for a gas turbine engine, viewing axis on, through the exhaust

The next type of combustor is the cannular combustor; the term is a portmanteau of "can annular". Like the can type combustor, can annular combustors have discrete combustion zones contained in separate liners with their own fuel injectors. Unlike the can combustor, all the combustion zones share a common ring (annulus) casing. Each combustion zone no longer has to serve as a pressure vessel. The combustion zones can also "communicate" with each other via liner holes or connecting tubes that allow some air to flow circumferentially. The exit flow from the cannular combustor generally has a more uniform temperature profile,

which is better for the turbine section. It also eliminates the need for each chamber to have its own igniter. Once the fire is lit in one or two cans, it can easily spread to and ignite the others. This type of combustor is also lighter than the can type, and has a lower pressure drop (on the order of 6%). However, a cannular combustor can be more difficult to maintain than a can combustor. Examples of gas turbine engines utilizing a cannular combustor include the General Electric J79 turbojet and the Pratt & Whitney JT8D and Rolls-Royce Tay turbofans.

1.2.3.3 ANNULAR

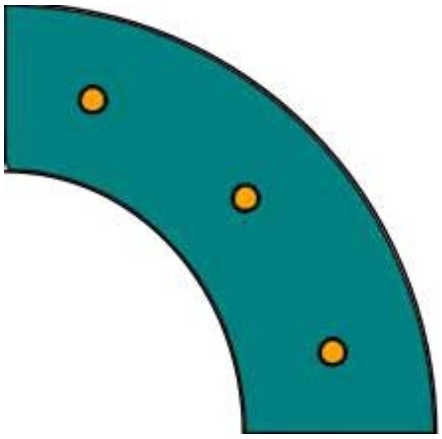

Figure.no: 1.4 Annular type combustion chamber

Annular combustor for a gas turbine engine, viewed axis on looking through the exhaust. The small orange circles are the fuel injection nozzles.

The final, and most commonly used type of combustor is the fully annular combustor. Annular combustors do away with the separate combustion zones and simply have a continuous liner and casing in a ring (the annulus). There are many advantages to annular combustors, including more uniform combustion, shorter size (therefore lighter), and less surface area. Additionally, annular combustors tend to have very uniform exit temperatures. They also have the lowest pressure drop of the three designs (on the order of 5%). The annular design is also simpler, although testing generally requires a full size test rig. An engine that uses an annular combustor is the CFM International CFM56. Almost all of the modern gas turbine engines use annular combustors; likewise, most combustor research and development focuses on improving this type.

1.2.3.4 DOUBLE ANNULAR COMBUSTOR

One variation on the standard annular combustor is the double annular combustor (DAC). Like an annular combustor, the DAC is a continuous ring without separate combustion zones around the radius. The difference is that the combustor has two combustion zones around the ring; a pilot zone and a main zone. The pilot zone acts like that of a single annular combustor, and is the only zone operating at low power levels. At high power levels, the main zone is used as well, increasing air and mass flow through the combustor. GE's implementation of

this type of combustor focuses on reducing NOx and CO2 emissions. A good diagram of a DAC is available from Purdue. Extending the same principles as the double annular combustor, triple annular and "multiple annular" combustors have been proposed and even patented.

1.2.4 EMISSION

One of the driving factors in modern gas turbine design is reducing emissions, and the combustor is the primary contributor to a gas turbine's emissions. Generally speaking, there are five major types of emissions from gas turbine engines: smoke, carbon dioxide (CO_2), carbon monoxide (CO), unburned hydrocarbons (UHC), and nitrogen oxides (NO_x).

Smoke is primarily mitigated by more evenly mixing the fuel with air. As discussed in the fuel injector section above, modern fuel injectors (such as airblast fuel injectors) evenly atomize the fuel and eliminate local pockets of high fuel concentration. Most modern engines use these types of fuel injectors and are essentially smokeless.

Carbon dioxide is a product of the combustion process, and it is primarily mitigated by reducing fuel usage. On average, 1 kg of jet fuel burned produces 3.2 kg of CO_2. Carbon dioxide emissions will continue to drop as manufacturers make gas turbine engines more efficient.

Unburned hydrocarbon (UHC) and carbon monoxide (CO) emissions are highly related. UHCs are essentially fuel that was not completely combusted, and UHCs are mostly produced at low power levels (where the engine is not burning all the fuel). Much of the UHC content reacts and forms CO within the combustor, which is why the two types of emissions are heavily related. As a result of this close relation, a combustor that is well optimized for CO emissions is inherently well optimized for UHC emissions, so most design work focuses on CO emissions.

Carbon monoxide is an intermediate product of combustion, and it is eliminated by oxidation. CO and OH react to form CO_2 and H. This process, which consumes the CO, requires a relatively long time ("relatively" is used because the combustion process happens incredibly quickly), high temperatures, and high pressures. This fact means that a low CO combustor has a long residence time (essentially the amount of time the gases are in the combustion chamber).[35]

Like CO, Nitrogen oxides (NO_x) are produced in the combustion zone. However, unlike CO, it is most produced during the conditions that CO is most consumed (high temperature, high pressure, long residence time). This means that, in general, reducing CO emissions results in an increase in NO_x and vice versa. This fact means that most successful emission reductions require the combination of several methods.

1.2.5 TURBINE

Hot gases leaving the combustor expand through the turbine. Typical materials for turbines include inconel and Nimonic. The hottest turbine vanes and blades in an engine have internal cooling passages. Air from the compressor is passed through these to keep the metal temperature within limits. The remaining stages do not need cooling.

In the first stage, the turbine is largely an impulse turbine (similar to a Pelton wheel) and rotates because of the impact of the hot gas stream. Later stages are convergent ducts that accelerate the gas. Energy is transferred into the shaft through momentum exchange in the opposite way to energy transfer in the compressor. The power developed by the turbine drives the compressor and accessories, like fuel, oil, and hydraulic pumps that are driven by the accessory gearbox.

1.2.5.1 STEAM TURBINES

Steam turbine are used for the generation of electricity in thermal power plants, such as plants using coal, fuel oil or nuclear fuel. They were once used to directly drive mechanical devices such as ships' propellers but most such applications now use reduction gears or an intermediate electrical step, where the turbine is used to generate electricity, which then powers an electric motor connected to the mechanical load. Turbo electric ship machinery was particularly popular in the period immediately before and during World War II, primarily due to a lack of sufficient gear-cutting facilities in US and UK shipyards.

1.2.5.2 GAS TURBINES

Gas turbine are sometimes referred to as turbine engines. Such engines usually feature an inlet, fan, compressor, combustor and nozzle (possibly other assemblies) in addition to one or more turbines.

1.2.5.3 TRANSONIC TURBINE

The gas flow in most turbines employed in gas turbine engines remains subsonic throughout the expansion process. In a transonic turbine the gas flow becomes supersonic as it exits the nozzle guide vanes, although the downstream velocities normally become subsonic. Transonic turbines operate at a higher pressure ratio than normal but are usually less efficient and uncommon.

1.2.5.4 CONTRA-ROTATING TURBINES

With axial turbines, some efficiency advantage can be obtained if a downstream turbine rotates in the opposite direction to an upstream unit. However, the complication can be counter-productive. A contra-rotating steam turbine, usually known as the Ljungström

turbine, was originally invented by Swedish Engineer Fredrik Ljungström (1875–1964) in Stockholm, and in partnership with his brother BirgerLjungström he obtained a patent in 1894. The design is essentially a multi-stage radial turbine offering great efficiency, four times as large heat drop per stage as in the reaction (Parsons) turbine, extremely compact design and the type met particular success in back pressure power plants. However, contrary to other designs, large steam volumes are handled with difficulty and only a combination with axial flow turbines (DUREX) admits the turbine to be built for power greater than ca 50 MW. In marine applications only about 50 turbo-electric units were during 1917-19, and during 1920-22 a few turbo-mechanic not very successful units were sold. Only a few turbo-electric marine plants were still in use in the late 1960s while most land plants remain in use 2010.

1.2.5.5 STATORLESS TURBINE

Multi-stage turbines have a set of static (meaning stationary) inlet guide vanes that direct the gas flow onto the rotating rotor blades. In a stator-less turbine the gas flow exiting an upstream rotor impinges onto a downstream rotor without an intermediate set of stator vanes (that rearrange the pressure/velocity energy levels of the flow) being encountered.

1.2.5.6 CERAMIC TURBINE

Conventional high-pressure turbine blades (and vanes) are made from nickel based alloys and often use intricate internal air-cooling passages to prevent the metal from overheating. In recent years, experimental ceramic blades have been manufactured and tested in gas turbines, with a view to increasing rotor inlet temperatures and/or, possibly, eliminating air cooling. Ceramic blades are more brittle than their metallic counterparts, and carry a greater risk of catastrophic blade failure. This has tended to limit their use in jet engines and gas turbines to the stator (stationary) blades.

1.2.5.7 SHROUDED TURBINE

Many turbine rotor blades have shrouding at the top, which interlocks with that of adjacent blades, to increase damping and thereby reduce blade flutter. In large land-based electricity generation steam turbines, the shrouding is often complemented, especially in the long blades of a low-pressure turbine, with lacing wires. These wires pass through holes drilled in the blades at suitable distances from the blade root and are usually brazed to the blades at the point where they pass through. Lacing wires reduce blade flutter in the central part of the blades. The introduction of lacing wires substantially reduces the instances of blade failure in large or low-pressure turbines.

1.2.5.8 SHROUDLESS TURBINE

Modern practice is, wherever possible, to eliminate the rotor shrouding, thus reducing the centrifugal load on the blade and the cooling requirements.

Bladeless turbine uses the boundary layer effect and not a fluid impinging upon the blades as in a conventional turbine.

1.2.5.9 WATER TURBINES

- Pelton turbine, a type of impulse water turbine.
- Francis turbine, a type of widely used water turbine.
- Kaplan turbine, a variation of the Francis Turbine.
- Turgo turbine, a modified form of the Pelton wheel.
- Cross-flow turbine, also known as Banki-Michell turbine, or Ossberger turbine.

1.2.6 NOZZLE

A propelling nozzle is a nozzle that converts the internal energy of a working gas into propulsive force; it is the nozzle, which forms a jet, that separates a gas turbine, being gas generator, from a jet engine.

After the turbine, the gases expand through the exhaust nozzle producing a high velocity jet. In a convergent nozzle, the ducting narrows progressively to a throat. The nozzle pressure ratio on a turbojet is high enough at higher thrust settings to cause the nozzle to choke.

If, however, a convergent-divergent de Laval nozzle is fitted, the divergent (increasing flow area) section allows the gases to reach supersonic velocity within the divergent section. Additional thrust is generated by the higher resulting exhaust velocity. Types are

- Convergent nozzle
- Divergent nozzle
- Convergent-divergent nozzle

1.2.6.1 CONVERGENT NOZZLE:

Convergent nozzles are used on many jet engines. If the nozzle pressure ratio is above the critical value convergent nozzle will choke, resulting in some of the expansion to atmospheric pressure taking place downstream of the throat (i.e., smallest flow area), in the jet wake. Although jet momentum still produces much of the gross thrust, the imbalance between the throat static pressure and atmospheric pressure still generates some (pressure) thrust.

1.2.6.2 DIVERGENT NOZZLE:

The supersonic speed of the air flowing into a scramjet allows the use of a simple divergent nozzle.

1.2.6.3 CONVERGENT-DIVERGENT (C-D) NOZZLE:

Engines capable of supersonic flight have convergent-divergent exhaust duct features to generate supersonic flow. Rocket engines the extreme case owe their distinctive shape to the very high area ratios of their nozzles.

When the pressure ratio across a convergent nozzle exceeds a critical value, the flow chokes, and thus the pressure of the exhaust exiting the engine exceeds the pressure of the surrounding air and cannot decrease via the conventional Venturi effect. This reduces the thrust producing efficiency of the nozzle by causing much of the expansion to take place downstream of the nozzle itself. Consequently, rocket engines and jet engines for supersonic flight incorporate a C-D nozzle which permits further expansion against the inside of the nozzle. However, unlike the fixed convergent-divergent nozzle used on a conventional rocket motor, those on turbojet engines must have heavy and expensive variable geometry to cope with the great variation in nozzle pressure ratio that occurs with speeds from subsonic to over Mach 3.

1.2.7 THRUST AUGMENTATION

Thrust was most commonly increased in turbojets with water/methanol injection or afterburning. Some engines used both at the same time.

Liquid injection was tested on the Power Jets W.1 in 1941 initially using ammonia before changing to water and then water-methanol. A system to trial the technique in the Gloster E.28/39 was devised but never fitted.

1.2.7.1 AFTERBURNER

An afterburner or "reheat jet pipe" is a combustion chamber added to reheat the turbine exhaust gases. The fuel consumption is very high, typically four times that of the main engine. Afterburners are used almost exclusively on supersonic aircraft, most being military aircraft. Two supersonic airliners, Concorde and the Tu-144, also used afterburners as does Scaled Composites White Knight, a carrier aircraft for the experimental SpaceShipOne suborbital spacecraft.

Reheat was flight-trialled in 1944 on the W.2/700 engines in a Gloster Meteor I

1.2.8 CYCLE IMPROVEMENTS

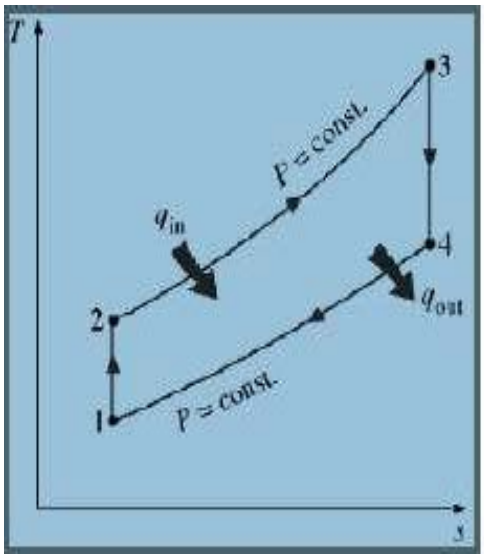
The operation of a turbojet is modelled approximately by the Brayton cycle.

The efficiency of a gas turbine is increased by raising the overall pressure ratio, requiring higher-temperature compressor materials, and raising the turbine entry temperature, requiring

better turbine materials and/or improved vane/blade cooling. It is also increased by reducing the losses as the flow progresses from the intake to the propelling nozzle. These losses are quantified by compressor and turbine efficiencies and ducting pressure losses. When used in a turbojet application, where the output from the gas turbine is used in a propelling nozzle, raising the turbine temperature increases the jet velocity. At normal subsonic speeds this reduces the propulsive efficiency, giving an overall loss, as reflected by the higher fuel consumption, or SFC. However, for supersonic aircraft this can be beneficial, and is part of the reason why the Concorde employed turbojets. Turbojet systems are complex systems therefore to secure optimal function of such system, there is a call for the newer models being developed to advance its control systems to implement the newest knowledge from the areas of automation, so increase its safety and effectiveness.

1.3 THERMODYNAMIC CYCLE

Thermodynamic working cycle for the jet engine is based on Brayton cycle. It is an open cycle (but usually represented as closed for thermodynamic analysis) designed for a piston engine and it is basis for the gas turbine engine cycle. T-s diagram of ideal Brayton cycle is shown here in Figure 4 with processes associated.



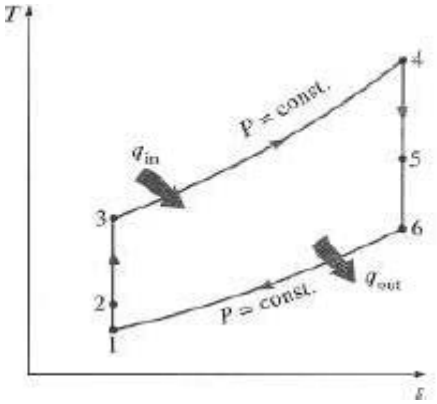
1-2, isentropic compression
2-3, constant pressure combustion
3-4, isentropic expansion
4-1, constant pressure heat release

Figure.no: 1.5 T-s Diagram for the ideal closed Brayton cycle

1.4 IDEAL TURBOJET CYCLE

Temperature-entropy (T-s) diagram of the ideal jet engine cycle is shown in Figure 5. The pressure of the air rises slightly as it is decelerated in the diffuser. Then, air is compressed by

the compressor. It is mixed with fuel in the combustion chamber, where the mixture is burned at constant pressure. The high-pressure and high-temperature combustion gases partially expand in the turbine, producing enough power to drive the compressor and other auxiliary equipment. Finally, the gases expand in a nozzle to the ambient pressure and leave the aircraft at a high velocity



1-2, inlet flow decelerates in diffuser
2-3, flow is compressed in compressor
3-4, mixing and combustion in burner
4-5, flow is expanded in turbine
5-6, outlet flow accelerates in nozzle

Figure.no: 1.6 T-s Diagram for the ideal turbojet cycle

1.5 WORK DONE

For the ideal jet engine, work done on the turbine is assumed to be equal to the compressor work and the processes in the diffuser, the compressor, the turbine and the nozzle are assumed to be isentropic. So the net work done in a turbojet engine is zero. However, for the actual cycle analysis, the irreversibility associated with in the compressor, turbine, nozzle and diffuser should be considered. Therefore, in a steady state operation of the jet engine, the turbine and the compressor work should be equal. Any difference in these parameters runs engine into the transient mode of operation.

1.6 PERFORMANCE PARAMETERS

The performance parameters for an aero-engine are defined in this section. Each parameter has its formula.

1.6.1 SPECIFIC THRUST

This is the amount of output thrust per unit of mass flow entering the engine. It is particularly important to maximize specific thrust in applications where engine weight or volume is crucial for aircraft that fly at high Mach numbers where the drag per unit frontal area is high.

1.6.2 SPECIFIC FUEL CONSUMPTION

This is the mass of fuel burnt per unit time per unit of output power or thrust. It is important to minimize SFC for applications where the weight and/or cost of the fuel are significant. When specifying the SFC values, it is important to state whether the lower or higher calorific value of the fuel is used.

1.6.3 THERMAL EFFICIENCY

Thermal efficiency for jet engines is defined as the rate of addition of kinetic energy to the air divided by the rate of fuel energy supplied, usually expressed as a percentage. The energy in the jet is proportional to the difference in the squares of jet and flight velocities. Generally thermal efficiency increases as pressure ratio and SOT increase together, as these results in a higher jet velocity for a given energy input.

$$\eta_{th} = \frac{\text{increase in kinetic energy}}{\text{heat energy added}}$$

1.6.4 PROPULSIVE EFFICIENCY

Propulsive efficiency for jet engines is defined as the useful propulsive power produced by the engine divided by the rate of kinetic energy addition to the air, again usually expressed as a percentage. The net thrust is proportional to the difference in the jet and flight velocities. Since power is force times velocity, propulsive power is proportional to the flight speed times the difference in the jet and flight velocities. From the formula, propulsive efficiency is improved by low jet velocities, due to lower energy wastage as jet kinetic energy. This requires high pressure ratio and low SOT. However, low jet velocities produce lower thrust output, hence to achieve high propulsive efficiency, as well as a required thrust, high engine mass flow must be coupled with low jet velocities. This leads to engines of low specific thrust, which are large and heavy. Turbofan engines are based upon this principal.

$$\eta_p = \frac{FN * v_0}{\text{increase in kinetic energy}}$$

1.6.5 OVERALL EFFICIENCY

Overall efficiency of a jet engine is the product of the thermal and the propulsive efficiencies of the engine.

$$\eta_{ov} = \eta_{th} * \eta_{p}$$

CHAPTER-II
LITERATURE REVIEW

2.1 DYNAMIC PERFORMANCE

Hsiao-wei, D.chiang, and chih-nenghsu was conducting the experiment. In this project, they are 'investigating about the current steady and dynamic performance of a 12- pound thrust turbojet engine'. This program includes both design and off-design conditions in order to analyse the baseline performance of the engine. Using the pc-based data acquisition system we will able to test the engine for both steady and dynamic performance. A full engine testing setup was established for this study, a pc-based subsystem, and the subsystems of engine including starting system, fuel and control system, and oil lubrication system. The engine testing involved the bench testing of the engine, at 135000 rpm in order to establish the baseline performance including temperature, pressure, speed and thrust.

The engine was accelerated to top speed, decelerated to around 40,000 to 50,000rpm range then repeated cycle runs, and recorded data for stabilized running conditions. The engine performance was predicted using GASTURB program to provide the compressor map data. GASTURB is a software program used to calculate the design and off-design performance. An experimental analytical program was conducted toperform a study of small turbojet engine steady and dynamic performance.

This program was mainly to investigate the current performance of a 12-pound thrust turbojet engine, and also to provide modeling for future designs. Current tests did not reveal thrust drop-off after repeated cycle run times as previously cited, however, problems with rear ball bearing integrity after extended run times may becaused by the following over-temperature cited during dynamic performance testing. This dynamic performance testing has demonstrated performance enhancements at moderate to fast acceleration rates during this type of engine testing. Especially, during the fast acceleration, the design point of 12-pound thrust was achieved at 70% part speed.

However, quick throttle applications were found to cause temporary exhaust gas temperature (EGT) overshoot to as high as 2192°F(1200°C). In summary, this investigation of engine testing and analysis has provided very good insight of small turbojet engine performance. Taking advantage of the experimentally determined compressor performance map and actual small turbojet bench test results, a gas turbine cycle analysis software program was successfully used to predict both the steady state and transient dynamic performance of the engine. The results of the performance prediction program were then compared to actual engine test data with reasonably good agreements.

2.2 CONCEPTUAL DESIGN &MISSION ANALYSIS

Lindelarsion, Tomasgrorsledt, Konstantinosg.kypriarid was conducting this experiment. In this topic 'conceptual design &mission analysis for a geared turbofan and an rotor configuration' , they compared geared turbofan and open rotor configuration by the multidisciplinary studies. So that the open rotor concept can offer a substantial fuel saving potential, compared to ducted fans for a given set of design consideration &customer requirement. These design point calculations were produced assuming constant engine overall pressure ratio, and turbine entry temperature and reflect mid cruise condition and optimal by-pass ratio for SFC. By improving fan and low-pressure turbine polytropic efficiency directly improves SFC; off-design performance effects as well as nacelle drag and engine weight was not considered.

The prediction of engine performance, aircraft design and performance, direct operating costs, and emissions for the two-engine design is made using the EVA code. The engine performance output is used as input in the conceptual design tool Weico for carrying out mechanical and aerodynamic design to drive engine component weight and dimensions. These two tools are integrated together and run in sequence using a commercial integration and optimization environment. Multi objective optimization, design studies, parametric studies, and sensitivity analysis can readily be performed within this environment. In this paper a comparison between a geared turbofan engine and a geared open rotor engine with year 2020 technology level was carried out. Design constraints in the form of customer requirements (such as time between overhaul, runway length, time to height etc.) as well as technology limitations (such as component efficiencies, maximum stage Loading , minimum blade height etc.) were taken into consideration.

Although the open rotor engine is somewhat heavier, the reduced SFC and nacelle drag makes up for this and the resulting mission fuel burn is improved by approximately 15% compared to the geared turbofan engine. It can also be observed that for the open rotor configuration the location of the mid cruise operating point is not at the bottom of the SFC loop. Sizing the engine and choosing an appropriate design point for the propeller involves complex trade- offs, since for short haul aircraft large parts of the business case mission is spent climbing to cruise altitude, rather than cruising.

There is not only a great potential to reduce fuel consumption for the open rotor engine, and consequently decrease the CO2 emissions however the open rotor engine also demonstrates similar cruise EINOx figures compared to turbofan concepts, as well as similar margins from ICAO NOx certification limits. With current fuel prices, 6% lower DOC can be expected from the geared open rotor concept than from the GTF. This figure is very sensitive to the fluctuation of fuel prices.

If the fuel price increases then the impact of fuel consumption on the DOC will be even higher. The question then rises is: "Can the potential reduction in DOC outweigh the technological risks involved in introducing an open rotor configuration into the market." The answer is left to be given by the choices the aero engine industry makes in the years to come.

2.3 OFF-DESIGN PERFORMANCE ANALYSIS

x.Zhao, s.Sahook. kyprianids and j. rantzerm.sielemann was conducting this experiment. In this topic 'off-design performance analysis of hybridised aircraft gas turbine', they are concentrated only off-design performance analysis. They are parallel hybrid concept to reduce the cost efficiency. The hybridization will help us to minimize the power efficiency. The benefit of hybridization appears primarily at the thermomechanical design. There are propulsion system powered from electrical system hold the potential to achieve zero fuel consumption. That the fuel consumption level will be reduced or reducing the purpose there are used to electrical energy. An existing engine equipped with such provisions for power off-take off is the Rolls Royce Trent100.

As required by the more electric aircraft boeing787, which features no bleed air but ahigh power extraction requirement, extracting power from the intermediate pressure shaft has the benefits of enabling high power take off and improving operability of intermediate pressure compressor at low power. For engine performance prediction, an in-house tool was used along with open-source high performance computing platform for systems analysis and multi-disciplinary optimisation open MDAO. Open MDAO allows integration of different models created with different tools. The present work analysed the off-design performance of a geared turbofan under different degrees of hybridisation at different mission phases.

In more detail, the research has been focused on the operability of the compressors with varying hybridisation degrees and the potential of utilising hybridisation on the improvement of operability and specific fuel consumption. Through the baseline establishment, there is still some room for the conventional gas turbine improvement without major modifications to the current state-of-the-art configuration. About 1% of fuel burn can still be expected if the OPR can be pushed higher with better turbine materials capability. To hybridise the conventional gas turbine, as the case shown in the paper, the results indicate that positive hybridisation is good for high-load operations while negative hybridization can improve the operability of part-load operations. To be more specific, a take-off hybridization of 500kW gives a maximum of 0.5% cruise SFC by re-designing the turbine cooling flow system. Only minor changes need to be done to the engine core for the higher optimal

between engine operating/ maintenance costs and the resulting fuel burn increase is realised. Additionally, it is well supported if on-flight charging is needed for busy flights routes. Therefore, overall optimization of a flight mission would be highly specific with all the possibilities and trade-offs included.

2.4 PERFORMANCE MODELING OF AERO ENGINE

Sebastian Samuelsson, Konstantinosg.kyprianidis, Tomasgronstedt. In this paper 'consistent conceptual design and performance modeling of aero engine', they are concentrating mainly on the concept of conceptual design process of an engine. They providing addition of parameters indicating the level of technology assumed such as diffusion factor & stage loadings as part of the process. It represents the component technology level explicit, the ability to trade efficiency for weight or efficiency for cost. The traditional approach for the implementation of aero engine simulation systems has been to use two different modes in the simulation code, the design and off-design modes. For the design mode the governing equations are put in a form that allows the user to specify parameters that can easily be estimated at the preliminary stage of engine design.

The parameters specifying the design point are usually obtained from estimates on technology levels or projected technology levels. Using thermodynamic cycle analysis number of performance operating point, they find the efficiency of an engine. The benefit is obtained thoroughly exploring the pressure ratio distribution between the engine components, as a result of the consistent optimization methodology. The consistent conceptual design allows for the automatic trade of the number of turbomachinery stages against component and engine efficiencies. The implementation of a consistent conceptual design framework has been described, both from a perspective of numerical implementation and from a practical computational viewpoint. Implementing an automated consistent analysis re- duces the risk that component parameters are estimated incor rectly during the definition and optimization of an engine cycle.

The process also reduces the risk that ad hoc engineering judgment influences the definition of analysis input. The use of linear parameter bounds combined with a back tracking algorithm showed to be particularly useful for obtaining a robust solution process while performing consistent conceptual design optimization. Since most commercial gas turbine performance tools use secant methods with a Broyden update, this approach should generally be a useful one and it is recommended. However, for the optimization process, the choice is more open.

The algorithm described for consistent conceptual design optimization is independent of optimizer and the choice of optimizer depends on the topology of the search space, i.e., whether the gas turbine design space is multi-modal. In addition, computational performance requirements should be considered when selecting optimizer. In this study, an SQP method was successfully applied, but genetic algorithm based optimizers should work equally well, albeit with an expected performance penalty. Through example, it is illustrated that consistent conceptual design allows for the automatic trade of the number of turbomachinery stages

Against component and engine efficiencies. This is illustrated by the year 2030 engines for which the consistent polytropic efficiency optimization established a lower SFC despite the fact that the stage numbers were fixed to the year 2020 configuration. By optimally redistributing pressure ratio between the components and fully exploring the design space, the limitations of constant stage numbers could be compensated for.

2.5 THERMODYNAMIC ANALYSIS

Santosh Yarlagadda , was conducting this experiment. Jet engines are required to operate at a higher rpm for the same thrust values in cases such as aircraft landing and military loitering. High rpm reflects higher efficiency with increased pressure ratio. This work is focused on 'performance analysis of a J85 turbojet engine with an inlet flow control mechanism to increase rpm for same thrust values'. Developed a real-time turbojet engine integrating aerothermodynamics of engine components, principles of jet propulsion and inter component volume dynamics represented in 1-D non-linear unsteady equations. Software programs SmoothC and SmoothT were used to derive the data from characteristic rig test performance maps for the compressor and turbine respectively. Simulink, a commercially available model-based graphical block diagramming tool from MathWorks has been used for dynamic modeling of the engine. Dynamic Look-up tables in Simulink were used to interpolate the real-time performance of the engine from rig-test data. Simulink model for the J85 turbojet engine was verified for performance accuracy with available test data of the engine.

A flow control mechanism that produces a pressure drop across inlet is assumed and the analysis is carried with reduced compressor inlet pressure for matching thrust. Compressor inlet pressure is reduced to a percentage of atmospheric pressure and to produce the desired thrust with reduced inlet pressure, the engine operates at a higher shaft rpm. With increase in shaft rpm, pressure and temperature ratio values across the compressor-turbine assembly increases. Performance parameters of the engine are analyzed with the increase in compressor pressure ratio and shaft rpm.

Specific fuel consumption, specific thrust, component pressure ratios, thermal and propulsive efficiencies are the performance parameters of the engine that are analyzed on the model with reduced inlet pressure for the real-time test cases of desired thrust range. Limitations of the analysis are discussed along with possible industrial applications of this flow control mechanism. Overall performance of the turbojet engine decreases with reduced compressor inlet pressure for the same thrust if the engine is operated continuously with this mechanism. But has significant importance for applications where a certain amount of efficiency could be spent for the power demands.

It is observed that the thermal efficiency and fuel flow rate do not have a significant change in lower thrust range of operations. But the engine has the advantage of operating at a higher rpm. This particular application can be applied to any aircraft engine during the time of descent and landing. There will be cases where the aircraft need to gain maximum power from lower thrust range in the minimum time. For an example, consider the case where the aircraft is in its approach to landing. Engine at this point operates in the lower thrust rangezz

the times like a runway overshoot or a go-around landing case, the engine needs to regain its maximum thrust from the lower range in the minimum amount of time. It is at this particular case, the concept of flow control with reduced inlet pressure has a real-time application. Starting at the time of descent the flow control mechanism to reduce compressor inlet pressure is employed and the efficiency of the engine doesn't change much with this application. But the engine id operated at a 10% higher rpm than normal operation with 10% pressure drop across the inlet. If the engine needs to regain the maximum power for the cases as discussed, it could be achieved faster than the normal operation just by deploying the flow control mechanism.

With the reduction in the inlet pressure, the engine works at a higher rpm to produce the same thrust. This results with increase in the work output but decrease in the net work. Therefore, even with the increase in the compressor pressure ratio and turbine inlet temperature, the engine thermal efficiency goes down in a small proportion. With the higher exit jet velocities, propulsive efficiency of the engine also goes down in a very small proportion. SFC, Thermal and propulsive efficiencies are the major performance parameters for commercial engines. But for military engines, situations demand higher Specific Thrust.

Specific thrust for engine increases with reduced compressor inlet pressure. This is particularly important for the cases of shorter runways and higher climb rate. With increase in the specific thrust value, the frontal area of the engine could be decreased and it is extremely important for the military applications.

Thrust specific fuel consumption value increases with reduced inlet pressure. With increase in the specific fuel consumption value for an engine, the range value for the engine decreases. Thermal and Propulsive efficiencies are also decreasing with reduced inlet pressure. However, if the flow control mechanism is employed for certain time of flight such as landing or takeoff, performance decrease in these actors doesn't affect the engine operation. It is advantageous to employ the reduced compressor inlet pressure approach if the situation demands engine power to efficiency.

2.6 SUMMARY ;

The above papers studied detail to know about the performance analysis of engine and its various methods. So we are choosing a software analysis by using MATLAB. To input a constant performance parameters of jet engine to create a performance chart compared with the ideal cycle.

CHAPTER-III

FORMULAS

The performance of real cycles differs from that of ideal cycles for the following reasons.

(a) Because fluid velocities are high in turbo-machinery the change in kinetic energy between inlet and outlet of each component cannot necessarily be ignored. A further consequence is that the compression and expansion processes are irreversible adiabatics and therefore involve an increase in entropy.
(b) Fluid friction results in pressure losses in combustion chambers and heat-exchangers, and also in the inlet and exhaust ducts. (Losses in the ducts connecting components are often included in the associated component losses.)
(c) If a heat-exchanger is to be of economic size, terminal temperature differences are inevitable, i.e. the compressed air cannot be heated to the temperature of the gas leaving the· turbine.
(d) Slightly more work than that required for the compression process will be necessary to overcome bearing and 'windage' friction in the transmission between compressor and turbine, and to drive ancillary components such as fuel and oil pumps.
(e) The values of cPand y of the working fluid vary throughout the cycle due to changes of temperature and, with internal combustion, due to changes in chemical composition.
(f) The definition of the efficiency of an ideal cycle is unambiguous, but this is not the case for an open cycle with internal combustion.
Knowing the compressor delivery temperature, composition of the fuel, and turbine inlet temperature required, a straightforward combustion calculation yields the fuel/air ratio necessary; and a combustion efficiency can also be included to allow for incomplete combustion. Thus it will be possible to express the cycle performance unambiguously in terms of fuel consumption per unit net work output, i.e. in terms of the specific fuel consumption. To convert this t9 a cycle efficiency it is necessary to adopt some convention for expressing the heating value of the fuel.
(g) With internal combustion, the mass flow through the turbine might be thought to be greater than that through the compressor by virtue of the fuel added. In practice, about 1-2 per cent of the compressed air-is bled off for cooling turbine discs and blade roots, and we shall see later that the fuel/air ratio employed is in the region 0-01-0-02.
For many cycle calculations it is sufficiently accurate to assume that the fuel added merely compensates for this loss. We will assume in the numerical examples which follow that the mass flows through the compressor and turbine are equal. When turbine inlet temperatures higher than about 1350 K are used, the turbine blading must beinternally cooled as well as the disc and blade roots. We then have what is called an air-cooled turbine. Up to 15 per cent of the compressor delivery air might be bled for cooling purposes, and for an accurate estimate

of cycle performance it is necessary to account explicitly for the variation of mass flow through the engine.
So certain formulas are used to find the efficiency of an engine with losses. They are,

3.1 STAGNATION PROPERTIES:

The kinetic energy terms in the steady flow energy equation can be accounted for implicitly by making use of the concept of stagnation (or total) enthalpy.

$$(h_0-h)+1/2(0-c^2)=0$$

And thus h_0 is defined by

$$h_0=h+c^2/2$$

When the fluid is a perfect gas, CPT can be substituted for h, & the corresponding concept of stagnation temperature .T_0 is defined by

$$T_0=T+C^2/2\ C_P$$

$C^2/2C_P$ is called the dynamic temperature

T=static temperature

An idea of the order of magnitude of the difference between T_0& T is obtained by considering air at atmospheric temperature, for which c_p=1.005 KJ/Kg k, flowing at 100m/s .Then

$$T_0-T=100^2/(2*1.OO5*10^3)=5K$$

The stagnation pressure p_0 is defined in a similar way to T_0 but with the added restriction that the gas is imagined to be brought to rest not only adiabatically but also reversibly, ieisentropically. The stagnation pressure is thus defined by

$$P_0/P=(T_0/T)^{\gamma/(\gamma-1)}$$

3.2 Compressor and turbine efficiencies

A) ISENTROPIC EFFICIENCY

The efficiency of any machine, the object of which is the absorption or production of work is normally expressed in term of the ratio of actual and ideal work transfers . Because turbomachines are essentially adiabatic, the ideal process is isentropic and the efficiency is called an isentropic efficiency.

For compressor,

The isentropic efficiency for the compressor is

$$\eta_c=(T'_{02}-T_{01})/(T_{02}-T_{01})$$

for turbine,

The turbine isentropic efficiency is defined as

$$\eta_t=(T_{03}-T_{04})/(T_{03}-T'_{04})$$

B) POLYTROPIC EFFICIENCY:

When performing cycle calculation covering a range of pressure ratio, say to determine the optimum pressure ratio for a particular application, the question arises as to whether it is reasonable to assume fixed typical values of η_{c} & η_{t}.

These consideration have led to the concept of polytropic (or small stage) efficiency η_{∞}, which is defined as the isentropic efficiency of an elemental stage in the process such that it is constant throughout the whole process.

For a compression,

$$\eta_c=(P_2/P_1)^{(\gamma-1)/\gamma}-1/(P_2/P_1)^{(\gamma-1)/\eta\infty C}-1$$

For a turbine,

$$\eta_t=1-(1/(p_3/p_4))^{\eta\infty t(\gamma-1)/\gamma}/1-(1/(p_3/p_4)^{(\gamma-1)/\gamma})$$

$$T_{02}-T_{01}=T_{01}[(P_{02}/P_{01})^{(n-1)/n}-1]$$

Where $(n-1)/n=(\gamma-1)/\eta\infty c$, and

$$T_{03}-T_{04}=T_{03}[1-(1/P_{03}-P_{04})^{(n-1)/n}]$$

Where $(n-1)/n=\eta\infty t(\gamma-1)/\gamma$

3.3 PRESSURE LOSSES:

Pressure losses in the intake and exhaust ducting have been dealt with in the previous sub section. In the combustion chamber a loss in stagnation pressure(Δp_b)occurs due to the aerodynamic resistance of flame-stabilizing and mixing device and also due to momentum changes produced by the exothermic reaction.

$$P_{03}=P_{02}-\Delta p_b$$

$$P_{03}=P_{02}(1-((\Delta P_b/p_{02})$$

Heat-exchanger effictiveness:

$$\text{Effictiveness}=(T_{05}-T_{02})/(T_{04}-T_{02})$$

3.4 MECHANICAL LOSSES:

In all gas turbines, the power necessary to drive the compressor is transmitted directly from the turbine without any intermediate gearing. Any loss that occurs is therefore due only to bearing friction and windage.

$$W=(1/\eta_m)c_{p12}(T_{02}-T_{01})$$

We shall take η_m to be 99 percent for all numerical examples

3.5 VARIATION OF SPECIFIC HEAT:

The properties cp& γ play an important in the estimation of cycle performance, and it is necessary to take account of variations in values due to changing conditions through cycle. In general, for real gases over normal working ranges of pressure and temperature, $c_p$is a function of temperature alone. The same is true of γ because it is related to c_p by

$$\gamma-1/\gamma=\tilde{R}/Mc_p$$

3.6 SPECIFIC FUEL CONSUMPTION :

The performance of real cycles can be unambiguously expressed in terms of the specific fuel consumption

$$SFC = f/W_N$$

3.7 CYCLE EFFICIENCY :

$$\eta_t = W_N/fQ_{net,p}$$

The ratio of the maximum to minimum pressure in the cycle is 4.0 and the maximum cycle temperature is 1200 k. compressor and turbine isentropic efficiencies are 0.85. The compression pressure occurs in two stages, each having a pressure ratio of 2.0 with intercooling to 300 k in between.

CHAPTER-IV

SOFTWARE DESCRIPTION

4.1 MATLAB INTRODUCTION:

MATLAB is a multi paradigm numerical computing environment and proprietary programming language developed by math works. MATLAB allows matrix manipulations, plotting of functions and data, implementation of algorithms, creation of user interfaces, and interfacing with programs written in other languages.

Although MATLAB is intended primarily for numerical computing, an optional toolbox uses the MuPAD symbolic engine allowing access to symbolic computing abilities. An additional package, Simulink, adds graphical multi-domain simulation and model-based design for dynamic and embedded systems.

As of 2018, MATLAB has more than 3 million users worldwide. MATLAB users come from various backgrounds of engineering, science, and economics.

4.2 LANGUAGE

This is a high-level matrix /array language with control flow statements. Function, data structures, input/output, and object-oriented programming features. It allows both "programming in the small" to rapidly create quick and dirty throw-away programs, and "programming in the large" to create complete large and complex application programs.

4.3 HOW TO CREATE A GRAPH IN MATLAB

In the command window, define x as a vector of 50 linearly spaced values between 1 and 10. Define y as the sine function.

```
X=linespace(1,10,50);

Y=sin(x);
```

In the workspace panel in the MATLAB desktop, select the variables to plot. Use Ctrl+ click to select multiple variables.

Figure.no: 4.1 MATLAB desktop

Select the 2-d line plot from the gallery on the plot lab. For additional type click the arrow at the end of the gallery MATLAB creates the plot and displays the plotting commands at the command line.

Plot(x,y)

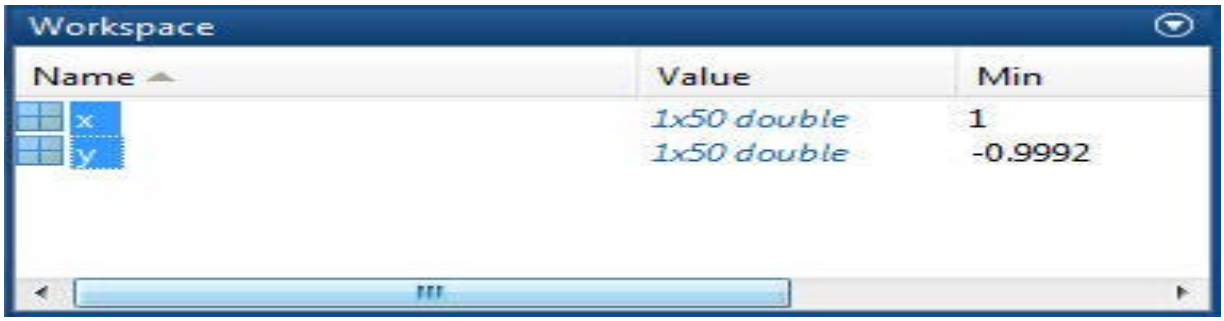


Figure.no: 4.2 MATLAB workspace

Functions

When creating a MATLAB function, the name of the file should match the name of the first function in the file. Valid function names begin with an alphabetic character, and can contain letters, numbers, or underscores. Variables and functions are case sensitive.

Function handles

MATLAB supports elements of lambda calculus by introducing function handles,[27] or function references, which are implemented either in .m files or anonymous/nested functions.

4.4 INTERFACING WITH OTHER LANGUAGE:

MATLAB can call functions and subroutines written in the programming languages C or Fortran. A wrapper function is created allowing MATLAB data types to be passed and returned. MEX files (MATLAB executables) are the dynamically loadable object files created by compiling such functions. Since 2014 increasing two-way interfacing with Python was being added.

Libraries written in Perl, Java, ActiveX or .NET can be directly called from MATLAB, and many MATLAB libraries (for example XML or SQL support) are implemented as wrappers around Java or ActiveX libraries. Calling MATLAB from Java is more complicated, but can be done with a MATLAB toolboxwhich is sold separately by MathWorks, or using an undocumented mechanism called JMI (Java-to-MATLAB Interface), (which should not be confused with the unrelated Java Metadata Interface that is also called JMI). Official MATLAB API for Java was added in 2016

As alternatives to the MuPAD based Symbolic Math Toolbox available from MathWorks, MATLAB can be connected to Maple or Mathematica. The MATLAB working environment. This is the set of tools and facilities that you work with as the MATLAB user or programmer. It includes facilities for managing the variables in your workspace and importing and exporting data. It also includes tools for developing, managing, debugging, and profiling M-files, MATLAB's applications.

Handle Graphics.
This is the MATLAB graphics system. It includes high-level commands for two-dimensional and three-dimensional data visualization, image processing, animation, and presentation graphics. It also includes low-level commands that allow you to fully customize the appearance of graphics as well as to build complete Graphical User Interfaces on your MATLAB applications.

4.5 THE MATLAB MATHEMATICAL FUNCTION LIBRARY:

This is a vast collection of computational algorithms ranging from elementary functions like sum, sine, cosine, and complex arithmetic, to more sophisticated functions like matrix inverse, matrix eigenvalues, Bessel functions, and fast Fourier transforms.

4.6 The MATLAB Application Program Interface (API):

This is a library that allows you to write C and Fortran programs that interact with MATLAB. It include facilities for calling routines from MATLAB (dynamic linking), calling MATLAB as a computational engine, and for reading and writing MAT-files.Libraries also exist to import and export MathML.

4.7 MATLAB APPLICATIONS IN AEROSPACE

- Developing the Apollo Lunar Module Digital Autopilot. ...
- Designing a High Angle of Attack Pitch Mode Control. ...
- Six Degrees of Freedom (6-DoF) Motion Platform. ...
- Aircraft Longitudinal Flight Control. ...
- Radar Tracking Using MATLAB Function Block. ...
- Optical Sensor Image Generation. ...
- Air Traffic Control Radar Design.

CHAPTER-V

RESEARCH METHODOLOGY

The analysis of engine performance, conceptual design and off-design performance of a small UAV turbojet engine is using a MATLAB code. Using design flow chart, MATLAB code is being developed for finding the performance parameters for different operating altitude and couple of operating Mach.No.

Performance of engine will be analysed for different operating altitude and operating Mach.No. Optimization of component performance will be done to achieve higher performance.

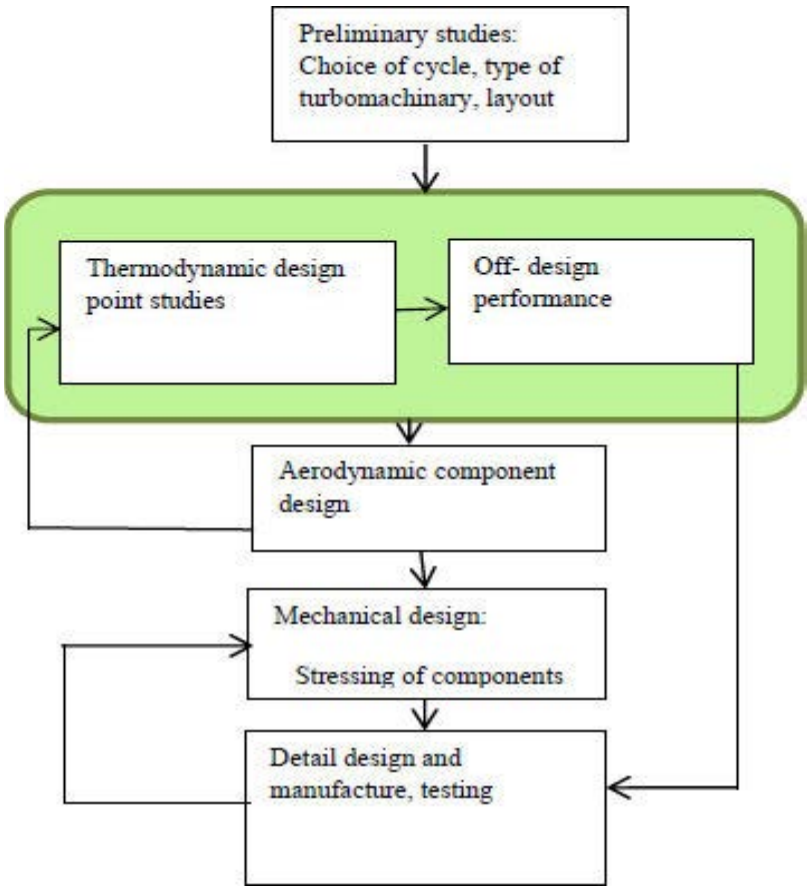

Figure.no: 5.1 Gas turbine design procedure adapted from Gas Turbine Theory by Cohen and Rogers.

5.1 Off-Design Performance of a Turbojet Engine

An engine is said to be running off-design if any of the following apply:

a) Change of throttle setting.
b) Change of altitude.
c) Change of flight speed.
d) Change of climate.
e) Change of installation.
f) Change in geometry.

Although each off-design point is effectively a design point calculation, the resulting cycle has the same turbine and nozzle geometry as that at the engine design point.

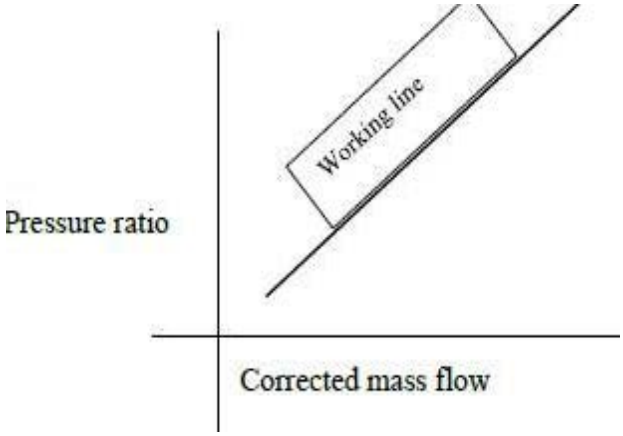

Figure.no: 5.2 Simple off-designs

Calculations of design points are usually carried out by a computer program. Such a program can also be used by adding an iterative loop to construct a quick, off-design model.
Thermodynamic point studies were used as the input for its off-design performance prediction. Other input values are atmospheric condition, isentropic efficiency, polytrophic efficiency, gas constant, mechanical transmission efficiency and combustion efficiency by using steady flow energy equation.

5.2 DESIGN DATA

PARAMETERS	**DATA**
Mach Number	0.8%
Altitude	1000%

CHAPTER-VII

COMPARITIVE GRAPH

In mathematics, and more specifically in graph theory, a graph is a structure amounting to a set of objects in which some pairs of the objects are in some sense "related". Typically, a graph is depicted in diagrammatic form as a set of dots or circles for the vertices, joined by lines or curves for the edges.

7.1 MACH NO VS SPECIFIC THRUST

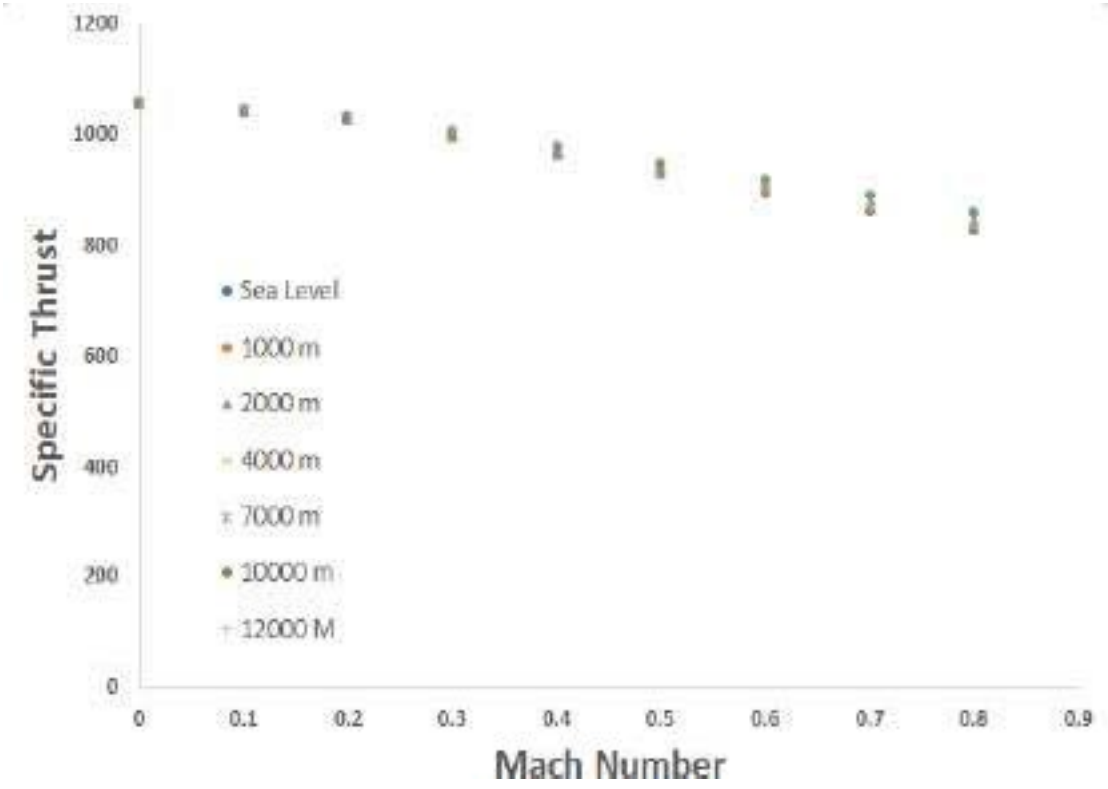

Figure.no:7.1 Mach number vs. Specific thrust

In this fig. 7.1 we compare Mach number vs specific thrust with various altitudes. The respective altitudes are 1000 m, 2000 m, 4000 m, 7000 m, 1000 m and 12000 m from the sea level and the Mach number varies from 0-0.8.The specific thrust slightly decrease from increase in altitude because of increase in momentum drag.

7.2 MACH NUMBER VS FUEL AIR RATIO

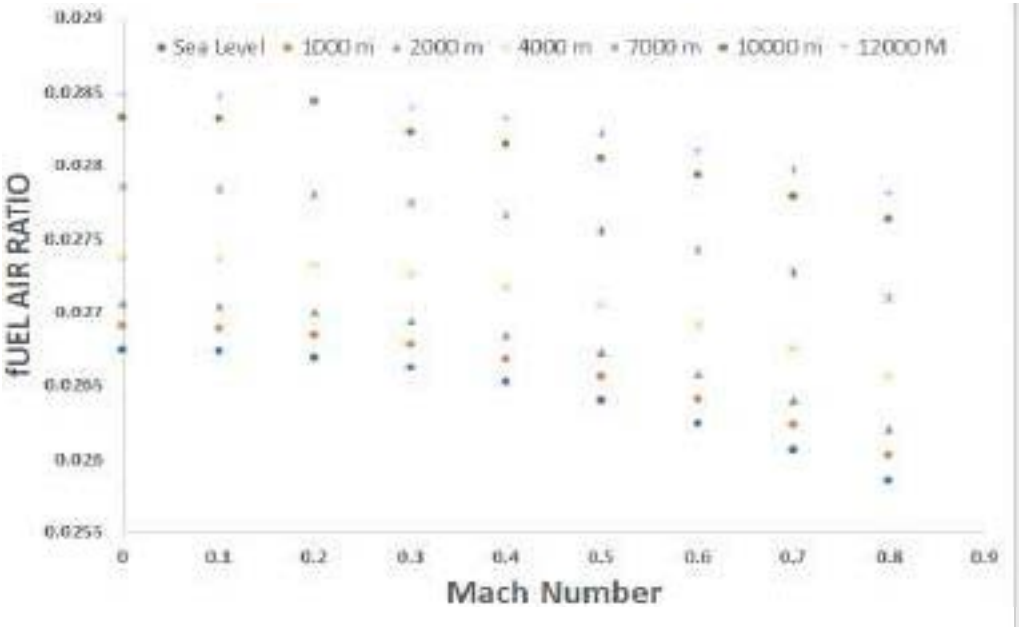

Figure.no:7.2 Mach number vs fuel air ratio

In this above fig.7.2 we compare both Mach number and fuel air ratio. The respective mach number is varies from 0.1,0.2,0.3,0.4,0.5,0.6,0.7 and 0.8. we are consider only subsonic speed. The consumption of fuel air ratio increases with increase in altitude. The graph explains the fuel air ratio slightly inversely proportional to the Mach number but directly proportional to the altitude.

7.3 MACH NO VS TSFC

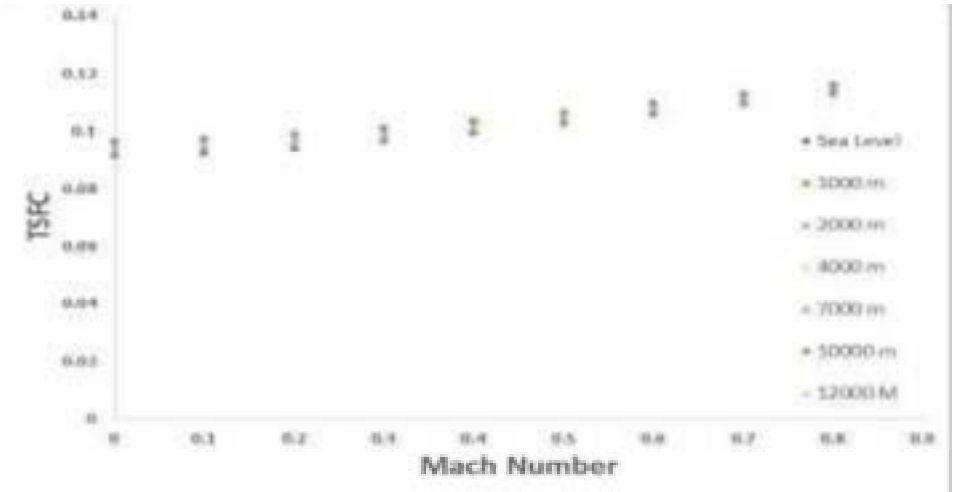

Figure.no:7.3 Mach number vs TSFC

In this fig.7.3 we compare both Mach number and thrust specific fuel consumption. The TSFC slightly increases with respect to the Mach number and different flight altitudes.

7.4 MACH NO VS PROPULSIVE EFFICIENCY

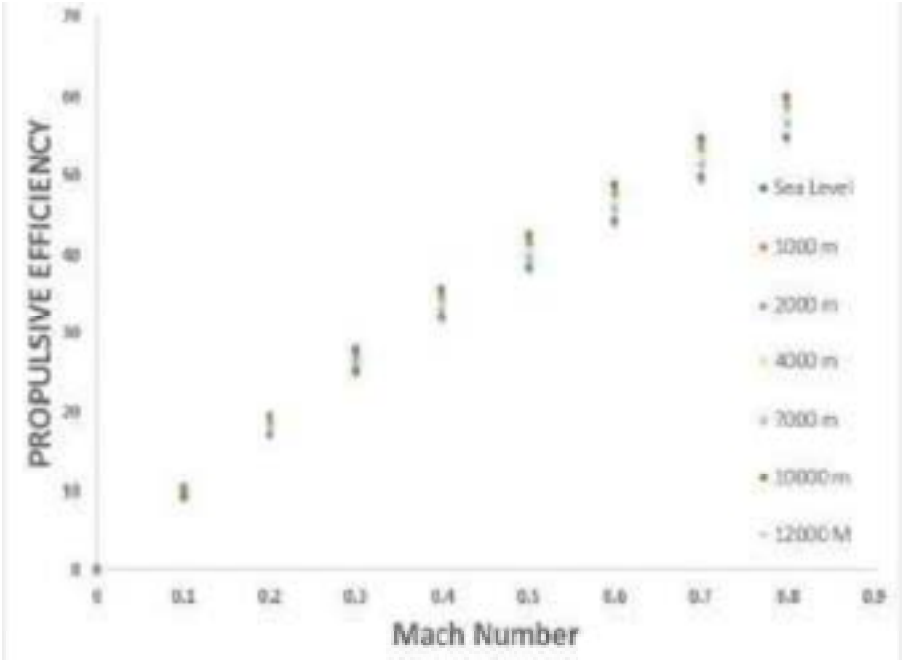

Figure.no:7.4 Mach number vs propulsive efficiency

In this fig. 7.4 we compare both Mach number and propulsive efficiency. It is also like a fig.11 Increases with respect to the both Mach number and different flight altitudes.

CHAPTER-VIII

CONCLUSION

The conceptual design of turbojet has been carried out using MATLAB code with the operating cycle assumptions of Brayton cycle with losses. Using the conceptual design approach, the performance parameters such as specific thrust, Propulsion efficiency, Thrust specific fuel consumption (TSFC) has been estimated through this cycle analysis for different operating mach number, compressor pressure ratio and the turbine inlet temperature. Fig illustrates the variation of specific thrust, propulsive efficiency and TSFC with operating mach number, the Compressor ratio and the turbine inlet temperature is constant. The variation of performance is taken for different altitudes from the sea level. The respective altitudes are 1000 m, 2000 m, 4000 m, 7000 m, 1000 m and 12000 m from the sea level. The mach number varies from 0 to 0.8. The Turbine inlet temperature is 1200 k and the compressor pressure ratio is 12.

At different flight conditions, the compressor ratio and the turbine inlet temperature is kept constant, the specific thrust and the fuel air mixture decreases slightly due to the decrease in the ambient pressure and density in the atmosphere.

Fig 7.1 shows that the increase of mach number at a fixed altitude also decreases the specific thrust because of the increase in the momentum drag. But the consumption of fuel-air mixture gets increased in increasing the altitude is shown in the fig 7.2.

The TSFC and Propulsive efficiency is not depending on the pressure and density of the air. They depend upon the temperature present in the engine. So the TSFC and the propulsive efficiency show improvement in their curves with respect to both mach number and the different flying altitudes is shown in the fig 7.4.

Hence the performance plot of the Turbojet engine is drawn for the above data.

Abstract: The selection of aero-engine that can meet the design specifications of aircraft is the primary step to the overall design program of an aircraft. Global aviation traffic is expected to increase at an annual rate of 5% for the foreseeable future. However, the engine emissions such as CO, CO_2, UHC, and NO_X have greater adverse impact on the earth atmosphere and human health in addition to its performance degradation. Proper design of the aero-engine to the design requirements of the particular aircraft is essential for meeting the highly competitive airline market. Turbojet is an air-breathing engine which works under the basis of Brayton Cycle. The efficiency and thrust produced by the engine depend on the individual performance of the turbojet components such as Intake, Compressor, Combustion Chamber, Turbine, and Propelling Nozzle in addition to its various operating atmospheric conditions. Here, program has been developed to do a conceptual design of the aero-engine using MATLAB and also performance analysis chart will be developed for the aero-engine to meet the design requirements of the aircraft. Keywords: MATLAB, off-design, thermodynamic analysis.

Nomenclature

Δh()	Stagnation enthalpy change
h_{pol}	Polytrophic efficiency
AR	Axial Aspect Ratio
CO2	Carbon dioxide
UHC	unburned hydrocarbon
EINOx	Nitrogen Oxides Emissions Index
EIS	Entry into Service
FAR	Federal Aviation Regulations
FB	Fuel Burn
FL	Flight Level
HPC	High Pressure Compressor
HPT	High Pressure Turbine
ICAO	International Civil Aviation Organization
IPC	Intermediate Pressure Compressor
ISA	International Standard Atmosphere
IPT	Intermediate Pressure Turbine
LR	Long Range
MT	Medium Term
NOx	Nitrogen Oxides
OPR	Overall Pressure Ratio
PW	Power
RQL	Rich-burn/Quick-quench/Lean-burn
SFC	Specific Fuel Consumption
SLS	Sea Level Static
SR	Short Range
T4	Burner exit temperature
T/O	Take-Off
TEC	Turbine Exhaust Case
TET	Turbine Entry Temperature

Introduction: Since the introduction of the first operational jet engine, engine development has been on larger engines to meet the increasing demands of thrust, SFC, specific thrust etc., Now a days there are numerous ideas to design an engine to increase the performance but before starting the process we are undergoing the conceptual design to analyze the performance characteristic to check the design satisfies our mission requirements. Conceptual design is the first step of the multiphase process involved in creating a new product. The conceptual design phase is conducted next to the schematic design phase. In this process we are using multiple input parameters like operating altitude, Mach.No & component efficiency like compressor ratio, turbine inlet temperature and mechanical transmission efficiency. To determine the compressor stagnation properties from compressor pressure ratio, work done on the compressor and isentropic efficiency of compressor and also find the turbine

ABSTRACT

The composite materials are replacing the traditional materials, because of its superior properties such as high tensile strength, low thermal expansion, high strength to weight ratio. Natural fiber composites such as sisal and jute polymer composites became more attractive due to their high specific strength, lightweight and biodegradability. Artificial composites such as Glass Fiber Reinforced Polymer, Carbon Fiber Reinforced Polymer having high strength, durability and non-biodegradability.

In this study, both the Natural (Jute fiber) and Artificial Composites (GFRP) are developed and their mechanical properties such as tensile strength, compression strength, bending test, fatigue strength, shear strength and impact strength are evaluated. The interfacial properties, internal cracks and internal structure of the fractured surfaces are evaluated.

INTRODUCTION

A composite is a structural material that consists of two or more combined constituents that are combined at a macroscopic level and are not soluble in each other. Composite materials are multiphase materials obtained through the artificial combination of different materials in order to attain properties that the individual components by themselves cannot attain.

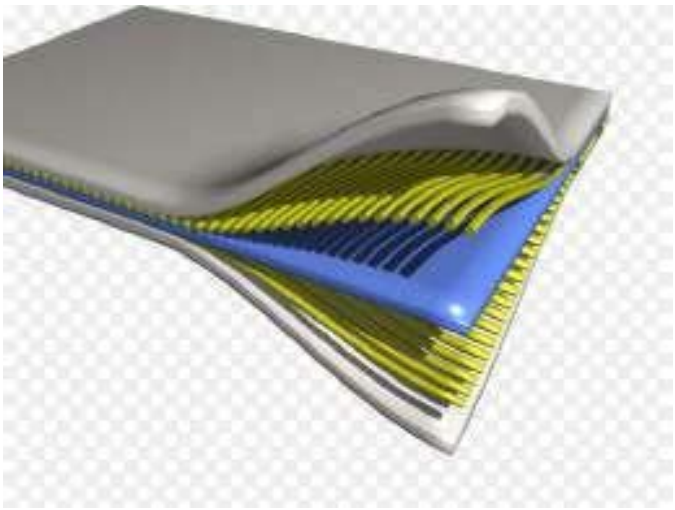

Fig No:1.1 Composite Material

One constituent is called the reinforcing phase and the one in which it is embedded is called the matrix. The reinforcing phase material may be in the form of fibers, particles, or flakes. The matrix phase materials are generally continuous. Examples of composite systems include concrete reinforced with steel and epoxy reinforced with graphite fibers, etc. If the composition occurs on a microscopic scale (molecular level), the new material is then called an alloy for metals or a polymer for plastics.

A composite material is composed of reinforcement (fibers, particles, flakes, and/or fillers) embedded in a matrix (polymers, metals, or ceramics). The matrix holds the reinforcement to form the desired shape while the reinforcement improves the overall mechanical properties of the matrix. When designed properly, the new combined material exhibits better strength than would each individual material.

1.1 HISTORY OF COMPOSITE MATERIALS

The first uses of composites date back to the 1500s B.C. when early Egyptians and Mesopotamian settlers used a mixture of mud and straw to create strong and durable buildings. Straw continued to provide reinforcement to ancient composite products including pottery and boats. Later, in 1200 AD, the Mongols invented the first composite bow. Using a combination of wood, bone, and "animal glue," bows were pressed and wrapped with birch bark. These bows were extremely powerful and extremely accurate. Composite Mongolian bows provided Genghis Khan with military dominance, and because of the composite technology, this weapon was the most powerful weapon on earth until the invention of gunpowder.

The modern era of composites did not begin until scientists developed plastics. Until then, natural resins derived from plants and animals were the only source of glues and binders. In the early 1900s, plastics such as vinyl, polystyrene, phenolic and polyester were developed. These new synthetic materials outperformed resins that were derived from nature. However, plastics alone could not provide enough strength for structural applications. Reinforcement was needed to provide the strength, and rigidity. In 1935, Owens Corning introduced the first glass fiber, fiberglass. It is combined with a plastic polymer creates an incredibly strong structure that is also lightweight. This is the beginning of the Fiber Reinforced Polymers (FRP) industry.

Many of the greatest advancements in composites were evolved during World War II. As the Mongols developed the composite bow, World War II also brought the FRP industry from the laboratory into actual production. Alternative materials were needed for lightweight applications in military aircraft. Engineers soon realized other benefits of composites beyond being lightweight and strong. It was discovered that fiberglass composites were transparent to radio frequencies, and the material was soon adapted for use in sheltering electronic radar equipment (Radomes).

By the end of the WWII, a small niche composites industry was in full swing. With lower demand for military products, the few composites innovators were now ambitiously trying to introduce composites into other markets. Boats were an obvious fit for composites, and the first commercial boat hull was introduced in 1946.At this time Brandt Goldsworthy, often referred to as the "grandfather of composites" developed new manufacturing processes and products. He is

credited with numerous advancements including being the first to fiberglass a surfboard, which revolutionized the sport. Goldsworthy also invented a manufacturing process known as pultrusion. Today, products manufactured from this process include ladder rails, tool handles, pipes, arrow shafts, armor, train floors, medical devices, and more.

In the 1970s the composites industry began to mature. Better plastic resins and improved reinforcing fibers were developed. DuPont developed an aramid fiber known as Kevlar, this fiber has become the standard in armor due to its high tenacity. Carbon fibers was also developed around this time since, it has been replacing metal as the new material of choice. The composite industry is still evolving, with much of the growth is now focused around Renewable energy.

Nowadays, Nanocomposites plays a vital role in composite industry. Nanocomposites refer to composites with nanometer-scale structure. This structure can relate to the grain size, the filler size, the pore size, etc. A small pore size helps to improve the mechanical strength of a porous material. A small grain size is attractive since it leads to a high yield strength in metals and a high toughness in ceramics. A small filler size provides a large filler–matrix interface area per unit volume. The idea behind Nanocomposites is to use building blocks with dimensions in nanometer range to design and create new materials with unprecedented flexibility and improvement in their physical and chemical properties.

1.2 TYPES OF COMPOSITE MATERIALS

Composite materials have undergone continuous development over the past 50 years, resulting in the evolution of a variety of new products. They may be broadly classified into two types, namely

- Natural Composites
- Artificial Composites

1.2.1 NATURAL COMPOSITES

Natural fiber composites are also claimed to offer environmental advantages such as reduced dependence on non-renewable energy/material sources, lower pollutant emissions, lower greenhouse gas emissions, enhanced energy recovery, and end of life biodegradability of components. Since, such superior environmental performance is an important driver of increased

future use of natural fiber composites, a thorough comprehensive analysis of the relative environmental impacts of natural fiber composites and conventional composites, covering the entire life cycle, is warranted.

Some of the examples for natural composites are listed below,

- Wood
- Bone
- Jute fiber
- Coconut fiber
- Cotton
- Bamboo

Fig no :1.2 Examples of Natural Composites

The natural composites are classified mainly in three biomaterial categories which are green composites, hybrid bio-composites, and textile bio-composites. In recent times, biological materials have become essential materials for the construction and automotive industry. Natural fibers and particles have been already used in various types of materials such as plastics, concrete, and textile products as strengthening part of the fiber/matrix combination. These composite materials have very good mechanical thermal and acoustical properties, hence they have been used in various engineering applications.

The wood-plastic composites (WPCs) have been used in many application areas as automobiles, constructions, marine, electronic and aerospace areas instead of fiber glass composites and steel materials. As a wood derivative, hemp fibers have been used in generating thermoplastic matrix composites. These composites can find its application area in the five sectors such as, the first area is to modify some parts of the internal and external automobile structures and electric cars. The second area is to obtain strong cementation in building construction. Another area is the production of durable clothes for army suppliers. The fourth one is to produce small electric hand tools and the last one is to build supercapacitors in carbon nanosheets which are as strong as graphene.

1.2.2 ARTIFICIAL COMPOSITES

Artificial composites are the structural material that consists of two or more combined constituents (including natural fibers sometimes) that are combined at a macroscopic level to obtain the new product. These Artificial Composites are more expensive than natural composites but, they offer high mechanical strength, less weight, more flexibility when compared to natural composites.

Some of the examples for Artificial composites are listed below,

- GFRP
- CFRP
- E-Glass
- S-Glass
- Aluminum Composites

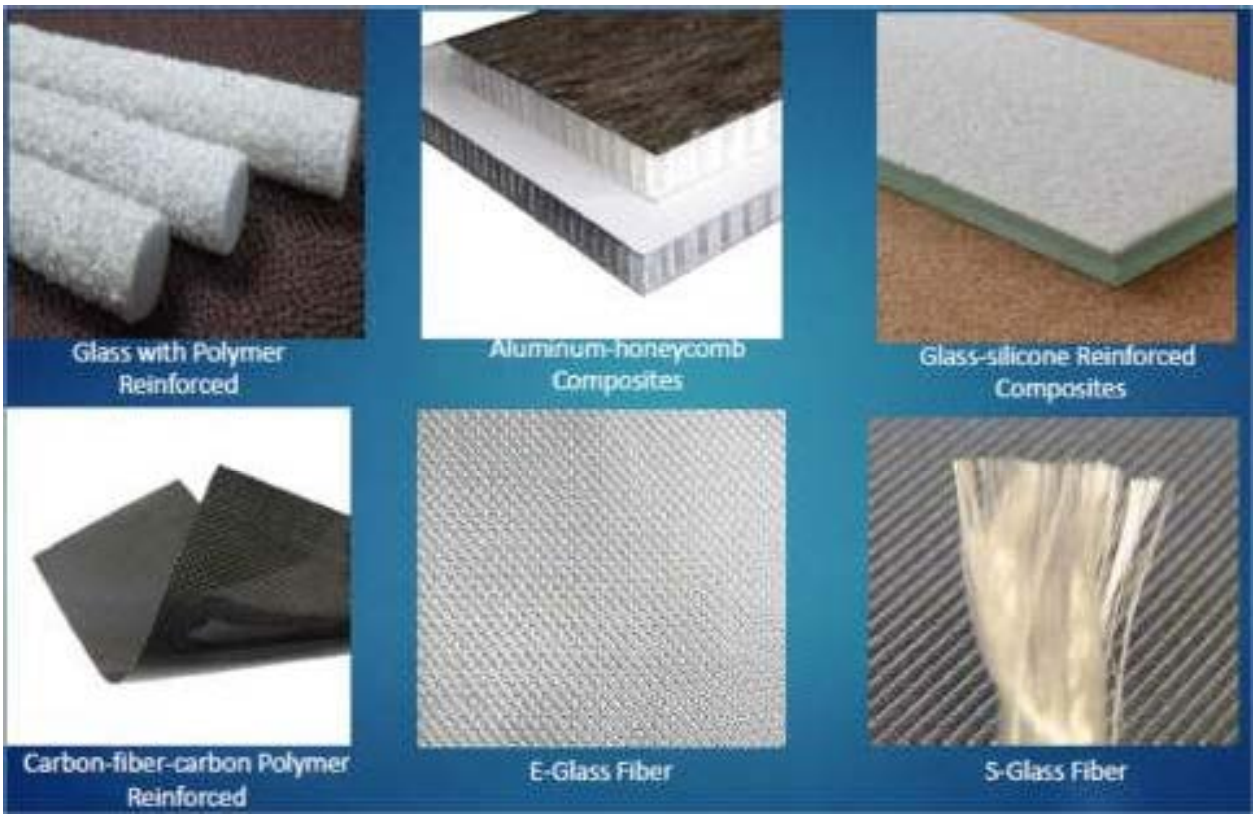

Fig no: 1.3 Examples of Artificial Composites

Carbon Fiber Reinforced Polymer (CFRP) is the most advanced among the above artificial composites.

1.3 CLASSIFICATION OF COMPOSITE MATERIALS

Composite Materials are classified into two different types based on their construction which are given below,

- Reinforcement Type
- Matrix Type

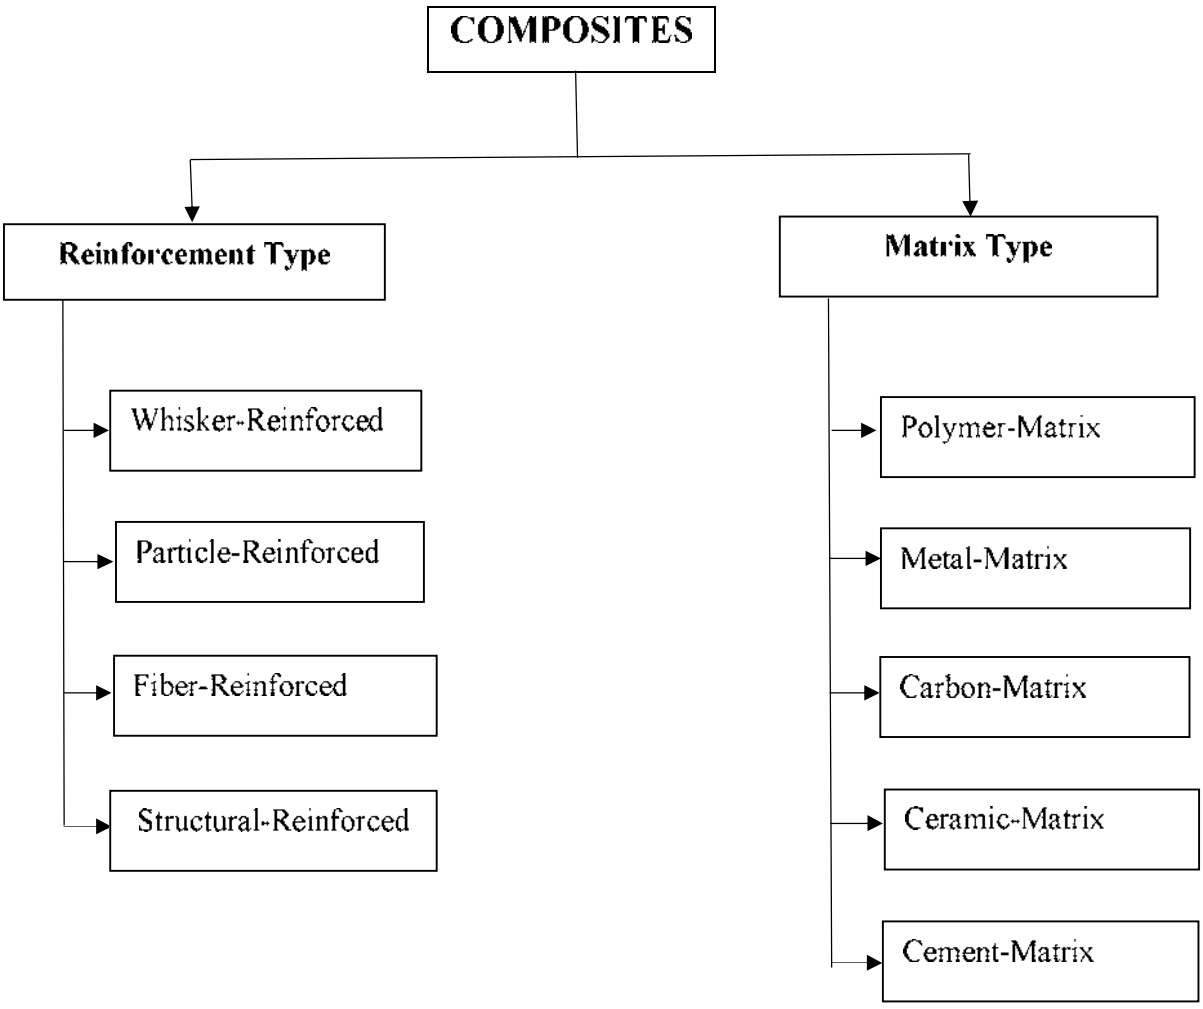

Fig no: 1.4 Classification of Composite Materials

1.3.1 REINFORCEMENT TYPE

Reinforced composites comprise a high-strength additive included with the virgin resin. The additive is usually glass, carbon, or Kevlar fiber. These fibers may be random, oriented, or in a mat format. In some cases, fine metal shavings are used. A common means of achieving this process is through spray up. A catalyst, resin, and chopped roving are all sprayed onto a mold. Filament winding is another reinforced composite method. In this process, a continuous fiber is wrapped repeatedly onto a mold to produce directional strength. A large portion of the filament

winding done in industry is custom manufacturing. Pultrusion is a third process by which reinforced composites are produced. This process allows for a composite of a constant profile to be continuously produced. The roving's or fibers are pulled through a resin, which impregnates the material. The part strengthens as the resin is allowed to cure.Composites reinforced with para-aramid fibers have low density, high strength and specific modulus, good tensile fatigue properties, but low compressive strength and interlaminar shear strength and difficulty in cutting process. It is generally difficult to obtain both good diametric tolerance and shredding-free surfaces for the composites reinforced with aramid fibers. To prevent shredding and surface de-laminations for a clean hole, this type of composite structure is preloaded by tensile stress and cut by shear force.

Composites fabrication is a largely specialized field. Thus, there are very few large companies that focus on composites fabrication to make the bulk of their income. These companies are usually self-managed as opposed to having a corporate office that oversees many smaller plants spread throughout the United States or the world. There are various types of Reinforced composites which are given as follows,

- Whisker-Reinforced Composites
- Particle- Reinforced Composites
- Fiber-Reinforced Composites
- Structural Composites

1.3.1.1 WHISKER-REINFORCED COMPOSITES

A whisker is a single crystal in the form of a fiber. Whiskers can be considered as a sub-group of fibers possessing shorter lengths compared to conventional fibers. They are among the strongest materials that we know of. Whiskers can be produced from materials like graphite, silicon carbide, aluminum oxide, iron, and alike as well as hydroxyapatite, dicalcium phosphate anhydrous, cellulose whiskers and other biomaterials. They are easily damaged, i.e. break to shorter lengths, during processing. They also tend to get oriented leading to unwanted anisotropy in composites. It is also very difficult to carry out large-scale manufacturing of whiskers that are

defect-free. Thus, they are very expensive. Whiskers also pose difficulty in packing compared to particulates; hence, it is not possible to achieve high reinforcement-to-matrix ratios.

1.3.1.2 PARTICLE- REINFORCED COMPOSITES

The particulate phase is harder and stiffer than the matrix. These reinforcing particles tend to restrain movement of the matrix phase in the vicinity of each particle. In essence, the matrix transfers some of the applied stress to the particles, which bear a fraction of the load. The degree of reinforcement or improvement of mechanical behavior depends on strong bonding at the matrix–particle interface. There are two subclassifications of particle-reinforced composites namely large-particle and dispersion-strengthened composites.

The term "large" is used to indicate that particle–matrix interactions cannot be treated on the atomic or molecular level in which continuous mechanics is used. The matrix transfers some of the applied stress to the particles, which bear a fraction of the load. Particles can have quite a variety of geometries, but they should be of approximately the same dimension in all directions (equiaxed). For effective reinforcement, the particles should be small and evenly distributed throughout the matrix. Furthermore, the volume fraction of the two phases influences the behavior; mechanical properties are enhanced with increasing particulate content

Dispersion-strengthened composites, particles are normally much smaller, with diameters between 0.01 and 0.1 m (10 and 100 nm). Particle–matrix interactions that lead to strengthening occur on the atomic or molecular level, whereas the matrix bears the major portion of an applied load, the small dispersed particles hinder or impede the motion of dislocations. Thus, plastic deformation is restricted such that yield and tensile strengths, as well as hardness, improve. Metals and metal alloys may be strengthened and hardened by the uniform dispersion of several volume percent of fine particles of a very hard and inert material. The dispersed phase may be metallic or nonmetallic sometimes, oxide materials are used.

Again, the strengthening mechanism involves interactions between the particles and dislocations within the matrix, as with precipitation hardening. The dispersion strengthening effect is not as pronounced as with precipitation hardening; however, the strengthening is

retained at elevated temperatures and for extended time periods because the dispersed particles are chosen to be unreactive with the matrix phase. For precipitation-hardened alloys, the increase in strength may disappear upon heat treatment as a consequence of precipitate growth or dissolution of the precipitate phase.

1.3.1.3 FIBER- REINFORCED COMPOSITES

The most important composites are those in which the dispersed phase is in the form of a fiber. Design goals of fiber-reinforced composites often include high strength and or stiffness on a weight basis. These characteristics are expressed in terms of specific strength and specific modulus parameters, which correspond, respectively, to the ratios of tensile strength to specific gravity and modulus of elasticity to specific gravity. Fiber-reinforced composites with exceptionally high specific strengths and moduli have been produced that utilize low-density fiber and matrix materials. The arrangement or orientation of the fibers relative to one another, the fiber concentration, and the distribution all have a significant influence on the strength and other properties of fiber-reinforced composites. With respect to orientation, two extremes are possible. They are, a parallel alignment of the longitudinal axis of the fibers in a single direction and a totally random alignment. Continuous fibers are normally aligned, whereas discontinuous fibers may be aligned, randomly oriented, or partially oriented. Better overall composite properties are realized when the fiber distribution is uniform.

Both inorganic and organic fibers are used in making structural composites. Inorganic fibers such as glass, boron, carbon, silicon carbide, silica, alumina, etc. are most commonly used. The structural grade organic fibers are comparatively very few in number. Aramid fibers are the most popular organic fibers. Another recent addition is a high strength polyethylene fiber which has a very low density and excellent impact resistant properties. The carbon fibers may also be grouped with organic fibers, although they are more often considered as ceramic (inorganic) fibers. Inorganic fibers in general are strong, stiff, thermally stable and insensitive to moisture. They exhibit good fatigue resistant properties, but low energy absorption characteristics. Organic fibers, on the other hand, are cheaper, lighter and more flexible. They possess high strength and better impact resistant properties.

1.3.1.4 STRUCTURAL COMPOSITES

A structural composite is normally composed of both homogeneous and composite materials, the properties of which depend not only on the properties of the constituent materials but also on the geometrical design of the various structural elements. Laminar composites and sandwich panels are two of the most common structural composites, only a relatively superficial examination is offered here for them.

A laminar composite is composed of two-dimensional sheets or panels that have a preferred high-strength direction such as is found in wood and continuous and aligned fiber-reinforced plastics. The layers are stacked and subsequently cemented together such that the orientation of the high-strength direction varies with each successive layer. For example, adjacent wood sheets in plywood are aligned with the grain direction at right angles to each other. Laminations may also be constructed using fabric material such as cotton, paper, or woven glass fibers embedded in a plastic matrix. Hence the laminar composite has relatively high strength in a number of directions in the two-dimensional plane.

Sandwich panels are considered to be a class of structural composites, are designed to be light-weight beams or panels having relatively high stiffnesses and strengths. A sandwich panel consists of two outer sheets, or faces, that are separated by and adhesively bonded to a thicker core. The outer sheets are made of a relatively stiff and strong material, typically aluminum alloys, fiber-reinforced plastics, titanium, steel, or plywood; they impart high stiffness and strength to the structure, and must be thick enough to withstand tensile and compressive stresses that result from loading. The core material is lightweight, and normally has a low modulus of elasticity.

Structurally, the core serves several functions. It provides continuous support for the faces. In addition, it must have sufficient shear strength to withstand transverse shear stresses, and also be thick enough to provide high shear stiffness. Another popular core consists of a "honeycomb" structure in which thin foils have been formed into interlocking hexagonal cells, with axes oriented perpendicular to face planes. The honeycomb material is normally either an aluminum alloy or aramid polymer. Strength and stiffness of honeycomb structures depend on cell size, cell wall thickness, and the material from which the honeycomb is made. Sandwich

panels are used in a wide variety of applications including roofs, floors, and walls of buildings; and, in aerospace and aircraft (i.e., for wings, fuselage, and tail plane skins).

1.3.2 MATRIX TYPE

The matrix is basically a homogeneous and monolithic material in which a fiber system of a composite is embedded. It is completely continuous. The matrix provides a medium for binding and holding reinforcements together into a solid. It offers protection to the reinforcements from environmental damage, serves to transfer load, and provides finish, texture, color, durability and functionality. There are various types of Reinforced composites which are given as follows,

- Polymer-Matrix Composites
- Metal-Matrix Composites
- Carbon-Matrix Composites
- Ceramic-Matrix Composites
- Cement-Matrix Composites

1.3.2.1 POLYMER-MATRIX COMPOSITES

Polymer-matrix composites are much easier to fabricate than metal-matrix, carbon-matrix, and ceramic-matrix composites, whether the polymer is a thermoset or a thermoplastic. This is because of the relatively low processing temperatures required to fabricate polymer-matrix composites. These matrices are prominent class of composites compared to other composite materials in commercial applications. Most of the PMCs use either carbon-graphite or aramid fibers, which are the main commercial fibers. Epoxy resin remains the most important matrix polymer.

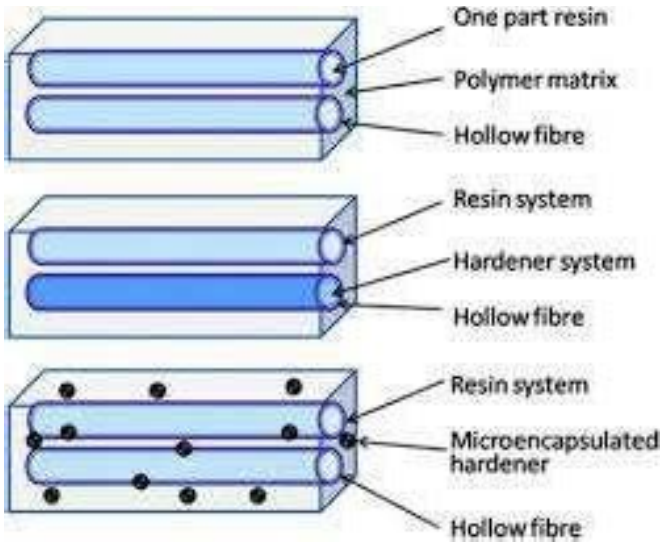

Fig no: 1.5 Polymer-Matrix Composites

1.3.2.2 METAL-MATRIX COMPOSITES

The processing of a metal-matrix composite tends to be much more expensive than that of a polymer-matrix composite due to the high processing temperature required. The fabrication of metal-matrix composites often involves the use of an intermediate, called a preform, in the form of sheets, wires, cylinders, or near-net shapes. A metal matrix composite (MMC) is composite material with at least two constituent parts, one being a metal necessarily, the other material may be a different metal or another material, such as a ceramic or organic compound. When at least three materials are present, it is called a hybrid composite. An MMC is complementary to a cermet. In comparison with conventional polymer matrix composites, MMCs are resistant to fire, can operate in wider range of temperatures, do not absorb moisture, have better electrical and thermal conductivity, are resistant to radiation damage, and do not display outgassing. On the other hand, MMCs tend to be more expensive, the fiber reinforced materials may be difficult to fabricate, and the available experience in use is limited.

Fig no:1.6 Metal-Matrix Composites

1.3.2.3 CARBON-MATRIX COMPOSITES

Carbon-matrix composites are made by the carbonization of the matrix of a polymer-matrix composite. The process of carbonization (also known as pyrolysis) is akin to charring, which involves a chemical reaction that removes essentially all atoms that are not carbon from the polymer. Carbon matrix composites (CMCs) are a complex family of advanced materials that consist of carbon or graphite fibers embedded in a carbon or graphite matrix. The carbon fiber reinforcement of these materials makes them stronger, tougher, and more resistant to thermal shock than conventional graphite. The specific advantages of carbon–carbon are light weight and low density, high strength and stiffness, high thermal conductivity, low coefficient of thermal expansion, high fracture toughness, and good fatigue and creep resistance. The combination of low expansion and high thermal conductivity means that carbon–carbon materials also possess excellent thermal shock resistance. Moreover, almost uniquely among materials, the strength of these composites increases with increasing temperature.

Fig no:1.7 Carbon-Matrix Composites

1.3.2.4 CERAMIC-MATRIX COMPOSITES

A ceramic-matrix composite (abbreviated to CMC) is commonly made from a polymer matrix composite by converting the polymer matrix to a ceramic. The process often involves thermal composition and, in this case, it is known as pyrolysis. For example, Polycarbo-silane (a polymer that has both carbon and silicon atoms) is often used as the precursor of silicon carbide. The fibers can be short or continuous. In both cases, the composites can be formed by viscous glass consolidation, either hot pressing a mixture of fibers and glass powder, or winding glass-impregnated continuous fiber under tension above the annealing temperature of the glass. Short fiber borosilicate glass composites are prepared by hot pressing, in vacuum or argon, using an isopropyl alcohol slurry of fibers and Pyrex powder. Long fibers are more difficult to disperse in the slurry. The resulting composite has fibers that are randomized two-dimensionally, as some alignment occurs during pressing.

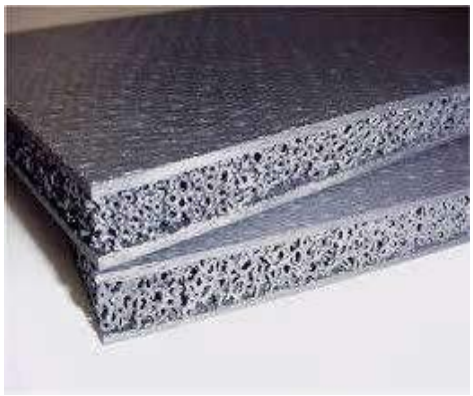

Fig no:1.8 Ceramic-Matrix Composites

1.3.2.5 CEMENT-MATRIX COMPOSITES

Cement is basically calcium silicate, where the SiO4 tetrahedron (with the silicon atom being *sp*3 hybridized and located at the body center of the tetrahedron, while the oxygen atoms are located at the four corners of the tetrahedron) is the fundamental building block. The realization of a cement-matrix composite does not require heat or pressure. Thus, the concrete processing can be performed in the field (as in road construction) rather than in a factory. The process involves mixing cement particles with water and allowing them to react.

This reaction is exothermic in which heat is released during the reaction and is known as hydration. Here, water enters the cement crystals and forms a gel that is a hydrate, particularly calcium silicate hydrate. Partly because of the difference in volume between the reaction products and the original material, shrinkage (commonly known as drying shrinkage) accompanies the hydration reaction.

In order to make sure that there is sufficient water available for the hydration reaction, the reaction is commonly conducted in a moisture chamber that has a high relative humidity. During the first 24h of the reaction, the originally fluid cement paste gradually becomes a rigid material that can thus be demolded if desired. This part of the hardening process is known as setting. However, the set material has not completed the hydration reaction, so the strength has not reached the desired high level. Therefore, setting is followed by curing for weeks.

While curing, the material is exposed to moisture for an extended period so as to allow the hydration reaction to approach completion.

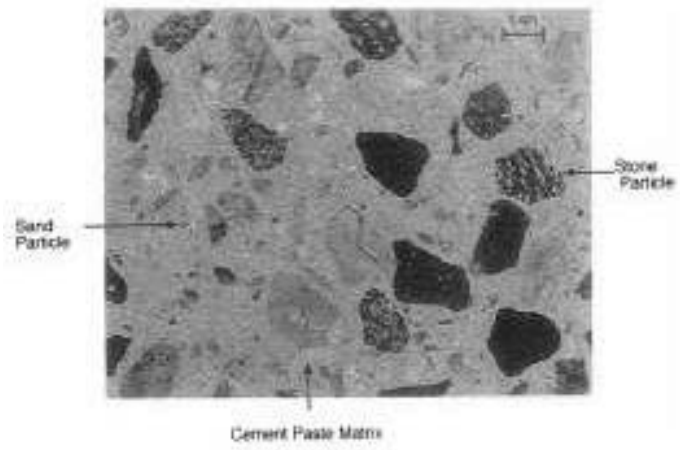

Fig no: 1.9Cement-Matrix Composites

1.4 FABRICATION OF COMPOSITE MATERIALS

Composite fabrication usually involves wetting, mixing or saturating the reinforcement with the matrix, and then causing the matrix to bind together (with heat or a chemical reaction) into a rigid structure. The operation is usually done in an open or closed forming mold, but the order and ways of introducing the ingredients varies considerably. Some of the methods involved in the fabrication process are listed below,

- Hand Lay-Up
- Automated Tape Lay-up
- Compression Molding
- Resin Transfer Molding
- Filament Winding
- Pultrusion Process
- Injection Molding
- Centrifugal Casting
- Continuous Laminating

1.4.1 HAND LAY-UP

Hand lay-up is a molding process where fiber reinforcements are placed by hand then wet with resin. The manual nature of this process allows for almost any reinforcing material to be considered, chopped strand or mat. Similarly, the resin and catalyst blend can be manipulated to allow for ideal processing conditions. Single sided, typically composite tools are used for this process.

Gel coat is first applied to the mold using a spray gun for a quality surface. When the gel coat has cured sufficiently, roll stock fiberglass reinforcement is manually placed on the mold. The laminating resin is applied by pouring, brushing, spraying, or using a paint roller. FRP rollers, paint rollers, or squeegees are used to consolidate the laminate, thoroughly wetting the reinforcement and removing entrapped air. Subsequent layers of fiberglass reinforcement are

added to build laminate thickness. Low density core materials such as end-grain balsa, foam, and honeycomb, are commonly used to stiffen the laminate.

Simple, single cavity molds of fiberglass composites construction are generally used. Molds can range from small to very large and are low cost in the spectrum of composites molds.

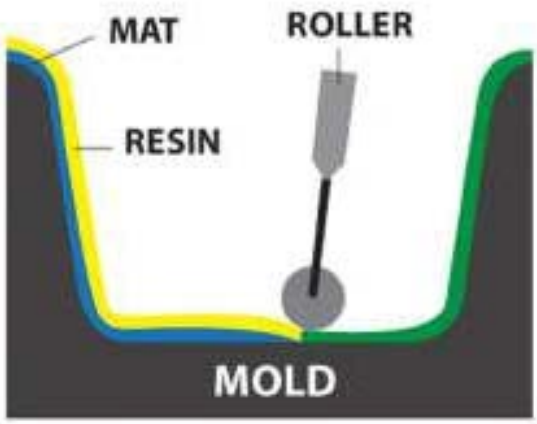

Fig no:1.10 Hand lay Up Method

1.4.2 AUTOMATED TAPE LAY-UP

Automated tape laying (ATL) is one of the most well-established automated manufacturing techniques for composites. Wide unidirectional tapes are laid onto a part mold using a loaded roller system with varying degrees of articulation, depending on the complexity of the part being manufactured. ATL essentially replicates the manual deposition of UD tape but can do so at higher speeds, on larger parts, with greater process control. Although not necessarily a fiber placement technique, modern ATL systems have precise control of tape start, cut, and orientation, allowing them to add more complex reinforcement than simply adding additional plies to the laminate.

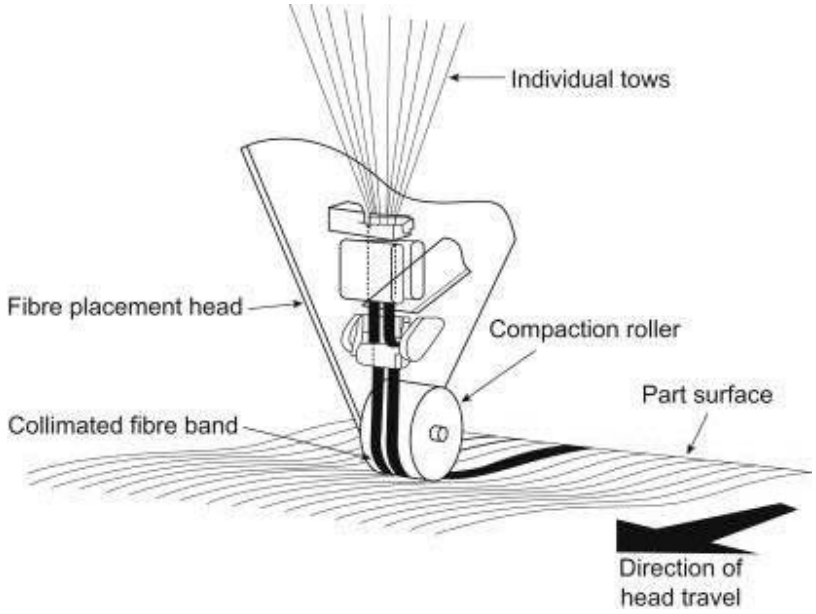

Fig no:1.11 Automated Tape Lay-Up

1.4.3 COMPRESSION MOLDING

Compression Molding is a method of molding in which the molding material, generally preheated, is first placed in an open, heated mold cavity. The mold is closed with a top force or plug member, pressure is applied to force the material into contact with all mold areas, while heat and pressure are maintained until the molding material has cured. The process employs thermosetting resins in a partially cured stage, either in the form of granules, putty-like masses, or preforms.

Compression molding is a high-volume, high-pressure method suitable for molding complex, high-strength fiberglass reinforcements. Advanced composite thermoplastics can also be compression molded with unidirectional tapes, woven fabrics, randomly oriented fiber mat or chopped strand. The advantage of compression molding is its ability to mold large, fairly intricate parts. Also, it is one of the lowest cost molding methods compared with other methods moreover it wastes relatively little material, giving it an advantage when working with expensive compounds.

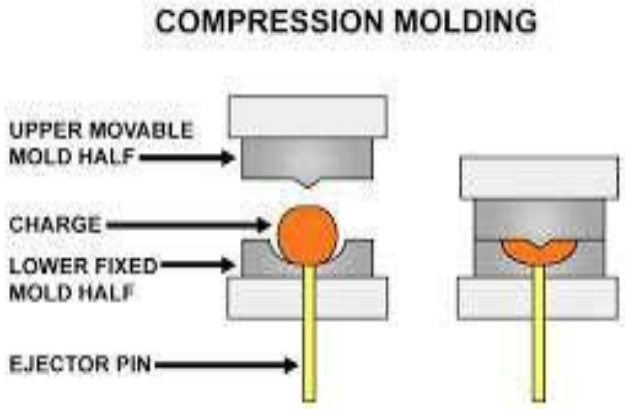

Fig no:1.12 Compression Molding

1.4.4 RESIN TRANSFER MOLDING

Resin transfer molding (RTM) is an intermediate volume molding process for producing composites. In RTM, resin is injected under pressure into a mold cavity. This process produces parts with two finished surfaces. By laying up reinforcement material dry inside the mold, any combination of material and orientation can be used, including 3-D reinforcements. Part thickness is determined by the tool cavity. Fast cycle times can be achieved in temperature-controlled tooling and the process can range from simple to highly automated. RTM can use a wide variety of tooling, ranging from low-cost composite molds to temperature-controlled metal tooling. Vacuum assist can be used to enhance resin flow in the mold cavity.

The mold is gel coated conventionally, if required. The reinforcement (and core material) is positioned in the mold and the mold is closed and clamped. The resin is injected under pressure, using mix/meter injection equipment, and the part is cured in the mold. The reinforcement can be either a preform or a pattern cut roll stock material. A preform is a reinforcement that is formed to a specific shape in a separate process and can be quickly positioned in the mold. RTM can be done at room temperature; however, heated molds are required to achieve fast cycle times and product consistency. Clamping can be accomplished with perimeter clamping or press clamping.

RTM can utilize either hard or soft tooling depending upon the expected duration of the run. Soft tooling would be either polyester or epoxy molds, while hard tooling may consist of cast machined aluminum, electroformed nickel shell, or machined steel molds. RTM can take advantage of the broadest range of tooling of any composites process. Tooling can range from very low-cost to high-cost, life-long molds.

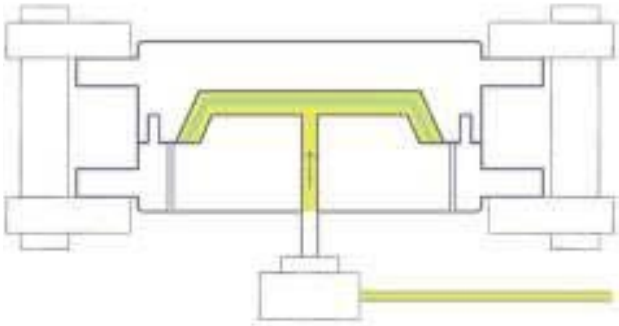

Fig no:1.13 Resin Transfer Molding

1.4.5 FILAMENT WINDING

Filament winding is a fabrication technique mainly used for manufacturing open (cylinders) or closed end structures (pressure vessels or tanks). This process involves winding filaments under tension over a rotating mandrel. The mandrel rotates around the spindle, while a delivery eye on a carriage traverses horizontally in line with the axis of the rotating mandrel, laying down fibers in the desired pattern or angle. The most common filaments are glass or carbon and are impregnated in a bath with resin as they are wound onto the mandrel. Once the mandrel is completely covered to the desired thickness, the resin is cured. Depending on the resin system and its cure characteristics, often the rotating mandrel is placed in an oven or placed under radiant heaters until the part is cured. Once the resin has cured, the mandrel is removed or extracted, leaving the hollow final product. For some products such as gas bottles, the 'mandrel' is a permanent part of the finished product forming a liner to prevent gas leakage or as a barrier to protect the composite from the fluid to be stored.

Filament winding is well suited to automation, and there are many applications, such as pipe and small pressure vessel that are wound and cured without any human intervention. The

controlled variables for winding are fiber type, resin content, wind angle, tow or bandwidth and thickness of the fiber bundle.

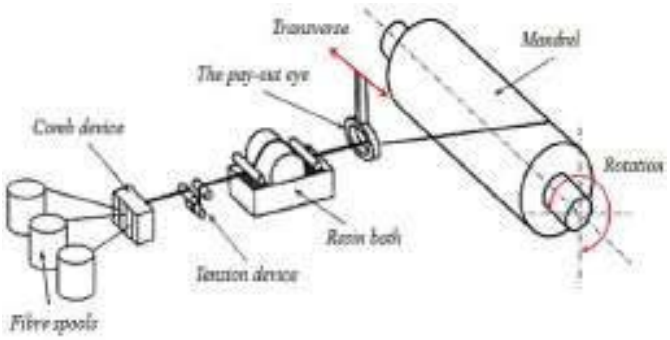

Fig no:1.14 Filament Winding

1.4.6 PULTRUSION PROCESS

Pultrusion is a continuous process for manufacture of splendorous materials with constant cross-section.

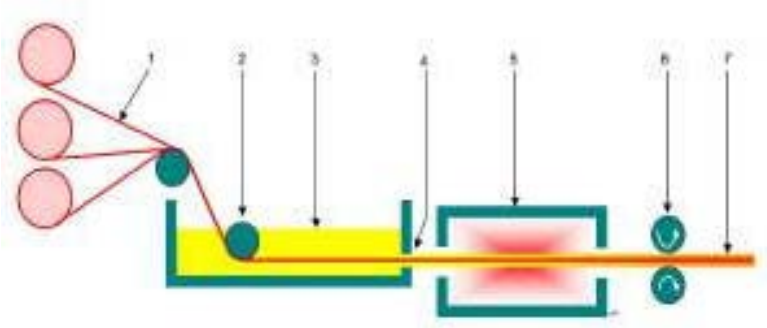

Fig no: 1.15 Pultrusion Process

1 – Continuous roll of reinforced fibers/woven fiber mat

2 – Tension roller

3 – Resin Impregnator

4 – Resin soaked fiber

5 – Die and heat source

6 – Pull mechanism

7 – Finished hardened fiber reinforced polymer

The process starts with the support of the reinforcements. These can be glass, carbon or aramid and in a roving/tow, mat, woven or stitched format. The material is pulled into the infeed area where it is accurately formed to the required shape and impregnated with a resin matrix. The resin matrix can be polyester, vinyl ester, epoxy or phenolic. From the infeed area the impregnated reinforcement is pulled into the heated pultrusion die.

The resin matrix is such that it solidifies and cures within the die. The cured profile exiting the die is allowed to cool before being clamped and pulled by the reciprocating puller units. The puller units reciprocate in a hand over hand motion, with the return stroke being faster than the pulling stroke to give a smooth continuous pull at a constant speed irrespective of the pulling force required. From the puller units the profile passes into the flying cut off saw where it is cut to the required length.

1.4.7 INJECTION MOLDING

Injection molding is a manufacturing process for producing parts by injecting molten material into a mold, or mold. Injection molding can be performed with a host of materials mainly including metals, glasses, commonly thermoplastic and thermosetting polymers. Material for the part is fed into a heated barrel, mixed, and injected into a mold cavity, where it cools and hardens to the configuration of the cavity. It is the most commonly used manufacturing process for the fabrication of plastic parts. A wide variety of products are manufactured using injection molding, which vary greatly in their size, complexity, and application. The injection molding process requires the use of an injection molding machine, raw plastic material, and a mold. The plastic is melted in the injection molding machine and then injected into the mold, where it cools and solidifies into the final part. The steps in this process are described in greater detail in the next section.

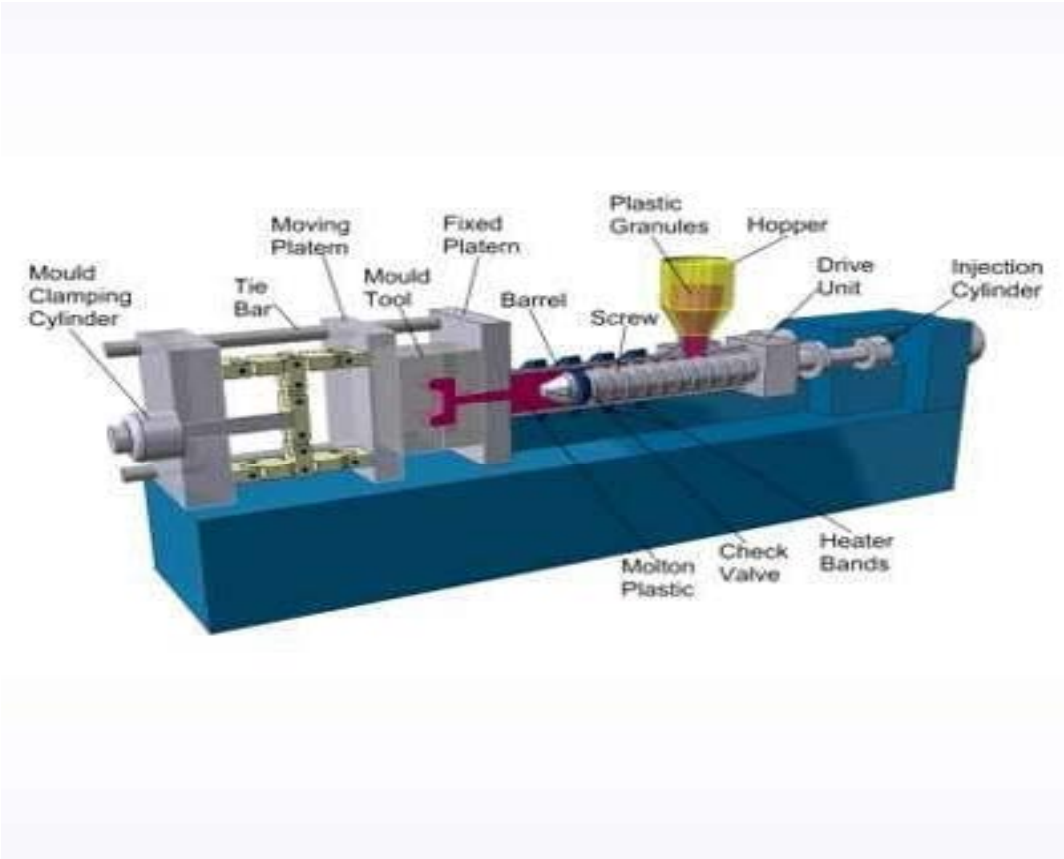

Fig no: 1.16 Injection Molding

1.4.8 CENTRIFUGAL CASTING

It is a process that delivers castings of very high material soundness, and thus is the technology of choice for applications like jet engine compressor cases, petrochemical furnace tubes, many military products, and other high-reliability applications.

In the centrifugal casting process, molten metal is poured into a spinning die. The die can be spinning either on a vertical or horizontal axis depending on the configuration of the desired part. Ring and cylinder type shapes are cast vertically; tubular shapes are made with the horizontal centrifugal process. Either process may be used to produce multiple parts from a single casting.

External structures and shaping can be cast in place to significantly reduce post-processing including machining or fabrication. Because of the high g-forces applied to the molten metal in the spinning die, less dense material, including impurities are subsequently

removed by machining. Typical materials that can be cast with this process are iron, steel, stainless steels and alloys of aluminum, copper and nickel. Two materials can be cast by introducing a second material during the process. Typical parts made by this process are pipes, boilers, pressure vessels, flywheels, cylinder liners and other parts that are axis-symmetric.

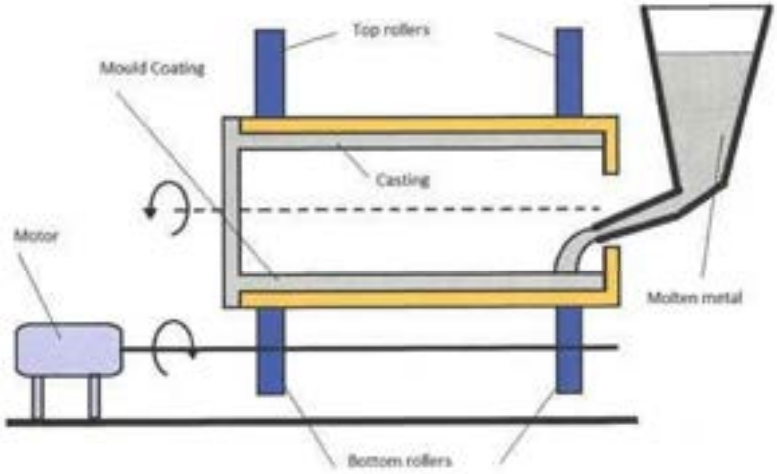

Fig no:1.17 Centrifugal Casting

1.4.9 CONTINUOUS LAMINATING

Continuous lamination is a highly automated process in which reinforcements are impregnated with resin and guided through a conveyor process of forming rolls to control thickness and resin content consistent with the desired end product. As the material on the conveyor is passed through a heating zone the resin is cured to form the composite panel. Panels and sheets manufactured in this process are used to produce truck trailer and RV sidewalls, skylights, building panels, and other construction industry applications.

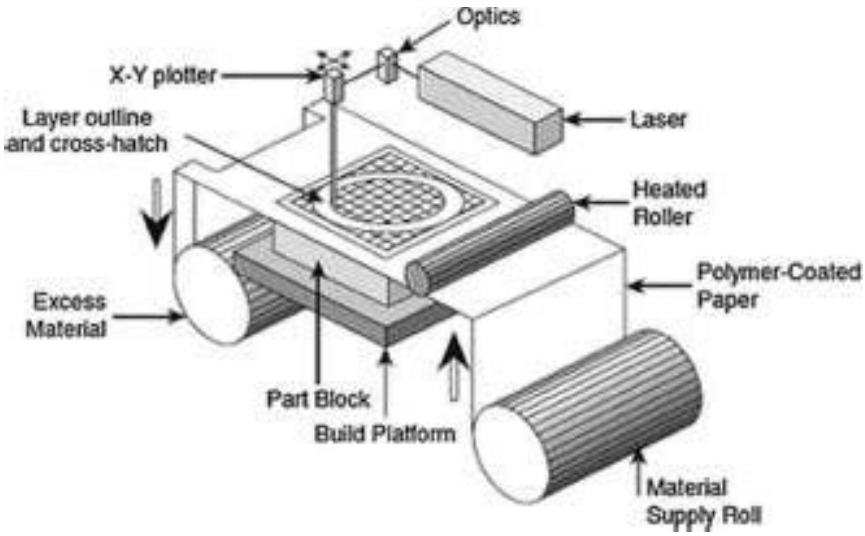

Fig no: 1.18 Continuous Lamination

1.5 CHARACTERISTICS OF COMPOSITE MATERIALS

The characteristic features of the composite materials are as listed below,

- High strength (as strong as high-strength steels).
- Low density (lower than aluminum).
- High stiffness (stiffer than titanium, yet much lower in density).
- Good creep resistance.
- Good fatigue resistance.
- Low friction coefficient and good wear resistance.
- Toughness and damage tolerance (as enabled by using appropriate fiber orientations).
- Chemical resistance (chemical resistance controlled by the polymer matrix).
- High thermal conductivity.
- Corrosion resistance.
- Dimensional stability.
- Vibration damping ability.
- Low electrical resistivity.
- High electromagnetic interference (EMI) shielding effectiveness.

1.6 ADVANTAGES OF COMPOSITE MATERIALS

The advantages of composite materials are as follows,

- **Design Flexibility** – Thermoset Composites give designers nearly unlimited flexibility in designing shapes and forms. They be molded into the most intricate components and can be made a wide range of densities and chemical formulations to have precise performance properties.
- **Low cost per cubic inch** – When comparing costs based on volume, thermoset composites have lower material costs than traditional materials such as wood, engineered thermoplastics and metals. In addition, because thermoset composites have a low petroleum-based content, they are not subjected to the price fluctuations experienced in petroleum-based products.
- **Lower material costs** – Because thermoset composites can be precisely molded, there is little waste and therefore significantly lower overall material costs than metals products.
- **Improved productivity** – Industrial Designers and Engineers are able to reduce assembly costs by combining several previously assembles parts into a single component. Also, inserts can be molded directly into the part during the molding process thereby eliminating the need for a post-process. In addition, composites do not usually require additional machining, thereby reducing work-in-process and time to market.

1.7 DISADVANTAGES OF COMPOSITE MATERIALS

The disadvantages of composite materials are as follows,

- **Delamination** - Since composites are often constructed of different ply layers into a laminate structure, they can "delaminate" between layers where they are weaker.
- **High Cost** - They are a relatively new material, and as such have a high cost.
- **Complex Fabrication** - The fabrication process is usually labor intensive and complex, which further increases cost.

- **Damage inspection** - Delamination and cracks in composites are mostly internal and hence require complicated inspection techniques for detection.

- **Composite to metal joining** - Metals expand and contract more on variations in temperature as compared to composites. This may cause an imbalance at joinery and may lead to failure.

Barring for the few disadvantages, composite materials are an almost perfect material for aircraft and fulfill most of the structural requirements. With further research progress in composite material damage control, the existing problems could also be controlled.

1.8 APPLICATIONS OF COMPOSITE MATERIALS

Some of the applications of composite materials are listed below,

- **Space craft**- Antenna structures, Solar reflectors, Satellite structures, Radar, Rocket engines, etc.
- **Aircraft**- Jet engines, Turbine blades, Turbine shafts, Compressor blades, Airfoil surfaces, Wing box structures, Fan blades, Flywheels, Engine bay doors, Rotor shafts in helicopters, Helicopter transmission structures, etc.
- **Industry**- Bearing materials, Pressure vessels, Abrasive materials, Electrical machinery, Truss members, Cutting tools, Electrical brushes, etc.
- **Automobiles**- Engines, bodies, Piston, cylinder, connecting rod, crankshafts, bearing materials, etc.

CHAPTER 2

LITERATURE SURVEY

Rahul Reddy Nagavally et al [1] "Composite Materials - History, Types, Fabrication Techniques, Advantages, and Applications" This paper presents a brief introduction of composite materials followed by history, fabrication techniques, advantages and applications. The individual components in the composite remains separate and distinct characteristics within the finished structure. The new material may be preferred for many reasons in which they are stronger, lighter, or less expensive when compared to traditional materials. More recently, researchers have also begun to actively include sensing, actuation, computation and communication into composites, which are known as Robotic Materials.

M.Ramesh et al [2] "Mechanical property evaluation of sisal–jute–glass fiber reinforced polyester composites" This paper reveals that the evaluation of mechanical properties by the reinforcement of Natural Composites (sisal–jute) with Artificial Composites (Glass fiber reinforced polyester) to determine that the jute-sisal mixture composite sample is capable of having maximum flexural strength, maximum impact strength, maximum tensile strength than the individual artificial composite GFRP by using Scanning Electron Microscope. The result indicates that the incorporation of sisal–jute fiber with GFRP can improve the properties and used as an alternate material for glass fiber reinforced polymer composites.

Jiayu Xiao et al [3] "Study on Processing and Properties of Jute Fiber Reinforced Polymer Matrix Composites" The fundamental performance, processing, mechanical properties and potential applications of jute fiber are discussed. The wettability between jute fiber and the three kinds of general resin matrices are quite good. The count of twisting jute fiber and thickness of jute fabric determines the tensile strength and bio-degradability factors are also included in this study.

S. Kandwal et al [4] "Processing and Characterization of Natural Fiber Reinforced Polymer Composites" The investigation of mechanical properties of Grewia Optiva (Bhimal) and jute fiber with epoxy resin matrix-based polymer composites indicates that the tensile, bending and abrasion behavior of composites material made by grewia optiva and jute into epoxy

resin have better tensile strength and flexural strength compared with the Gypsum-paper composites.

Hari Jana Raju et al [5] "Physical and Mechanical Characteristics of the Jute Fiber Reinforced Polymer Composites" Fabrication of unidirectional jute fiber reinforced epoxy-based composites have different fiber loading, density, void content and water absorption coefficients increases invariably with respect to its weight ratio. The mechanical properties of the composites are improved by adding the jute fiber as reinforcement in polymer matrix has been proved.

Sivasaravanan.S et al [6] "Mechanical Characterization of GFRP/CFRP/Natural Fiber Laminated in Epoxy Resin Composites" The composite consisting of an epoxy resin matrix reinforce with E-type glass fiber, Carbon fiber, Natural Fiber are used due to their high strength, light weight and free from corrosion. This research work will describe the fabrication of nano composite materials by hand layup technique and also gives the detailed report about the characteristic properties such as Mechanical properties and Morphological properties of Epoxy/GFRP/CFRP/Natural Fiber.

Ajith Gopinath et al [7] "Experimental Investigations on Mechanical Properties of Jute Fiber Reinforced Composites with Polyester and Epoxy Resin Matrices" is carried out to reveal that the jute epoxy exhibited better tensile and flexural properties. The processing time required for the jute polyester composite is very less compared to jute-epoxy composite. The results of this research indicate better mechanical properties for jute-epoxy, which makes it better suited for the automotive applications rather than jute-polyester composites.

Mubarak Ahmed Khan et al [8] "Study on the Mechanical Properties of Jute/Glass Fiber-reinforced Unsaturated Polyester Hybrid Composites and the effect of Surface Modification by Ultraviolet Radiation" The changes in tensile and flexural properties as a function of fiber content and as a consequence of UV radiation were investigated. Glass/jute was successfully reinforced in Unsaturated Polyester Hybrid (USP) resin and the mechanical performance was maximum at fiber loading. Different weight fractions of glass were added to the jute/USP composites and better mechanical properties, such as tensile and bending moduli were found at a jute to glass ratio. Due to the use of low-cost UV treatment as a surface modification technique and good balance of mechanical properties with proper hybridization, this type of composite can primarily be used for low-cost housing and automotive interior component applications.

Hazizan Md Akil et al [9] "Water absorption study on pultruded jute fiber reinforced unsaturated polyester composites" Comparative study of water absorption on the mechanical properties of jute fiber reinforced unsaturated polyester composite has been studied following different aqueous environments such as distilled water, sea water and acidic solutions at room temperature. The water absorption pattern is found to follow pseudo-Fickian behavior and therefore is predictable over a period of time.

Sgriccia.N et al [10] "Characterization of natural fiber surfaces and natural fiber composites" using FTIR, XPS, and ESEM. Water absorption experiments were also conducted to determine saturation mass gain. Alkali treated fiber composites absorbed more water than silane treated or untreated composites. The natural fiber composites absorbed more water than the glass fiber composites.

Joshi.S.V et al [11] "Natural fiber composites are environmentally superior to glass fiber reinforced composites" This studyCompares the life cycle and environmental performance of natural fiber composites with glass fiber reinforced composites find that the natural fiber composites are environmentally superior in the specific applications such as lower environmental impacts, fuel efficiency, pollution free and low cost.

Satheesh Raja. R et al [12] "Study on mechanical properties of fly ash impregnated glass fiber reinforced polymer composites using mixture design analysis" The study of fiber reinforced polymer and the fly ash impregnated fiber reinforced polymer composites are carried out to evaluate the mechanical properties such as tensile strength, compressive strength, hardness and impact strength and also the morphological properties of the fractured surfaces examined using SEM have revealed that the fly ash has better interaction with matrix which leads to better stress transfer and also to avoid the formation of cracks are discussed in this paper.

C. Santulli et al [13] "Impact damage characterization on Jute reinforced composites" These observations highlighted the characteristic patterns of impact damage and post-impact fatigue damage in jute reinforced laminates. On a set of specimens removed from the same plate, the impact-damaged area was also measured from low magnification micrographs. The dimension of impact-damaged area with the degradation of mechanical properties in jute reinforced composites are categorized.

Prabhuram.T et al [14] "Hybrid Composite Materials" deals with the analysis of hybrid composite materials. Hybridization is a process of incorporating synthetic fibers with that of

natural and metallic fibers in order to yield better strength, stiffness, high strength to weight ratio and other mechanical properties. This paper concerns with the development of new hybrid composite materials using Wood Powder, Groundnut Husk and Cashew nut Husk. Based on the physical, chemical and mechanical properties of the selected materials the required resins, catalysts and other accelerators are chosen and fabricated accordingly. The paper will present the Mechanical properties of the above mentioned eco-friendly and bio-degradable composites and the best possible applications of this composite materials.

M. S. Johari et al [15] "An experimental study on mechanical properties of GFRP braid-pultruded composite rods" The influence of over braiding on mechanical properties of pultruded rods, unidirectional (UD) rods, without braided fabric, were produced and those rod types were subjected to tensile, bending and torsion tests. The experimental results showed that BP rods have considerably higher shear modulus, but lower tensile modulus and flexural rigidity than those of UD pultruded rods, when fiber volume fraction is kept constant. Moreover, rods produced with higher braid roving linear densities had better torsional, but lower tensile and flexural properties. The highest shear modulus was observed in BP rods with braid angle of 45°.

Habib Tabatabai et al [16] "Tensile Strength and Bond Properties of GFRP Bars after Exposure to Elevated Temperatures" This paper reports residual tensile strength, modulus of elasticity, and bond strength of GFRP bars after exposure to elevated temperatures of up to 400 deg C and subsequent cooling to an ambient temperature. The results showed that the residual strength generally decreases with increasing temperature exposure. It concludes that the residual bond strength is a critical parameter in strength assessments of GFRP reinforced concrete members.

A. Adetiloye et al [17] "Mechanical Properties of Glass Fiber Reinforced Polymer Based on Resin from Recycled Plastic". It presents the mechanical performance properties of glass fiber reinforced plastic GFRP, based on resin recovered from recycled plastic waste. GFRP had a fiber content varied by weight, while the thicknesses of the laminate were minimum. The mechanical tests, conducted at room temperature, included tests for density, tensile strength, Izod impact energy, Brinell hardness number and tensile creep behavior. The results obtained in this study are in close agreement with the trend of variation of these parameters in GFRP, based on virgin resins. This confirms the applicability of GFRP based on recycled resin for structural uses. The successful application of plastic wastes in construction practice will generate multiple benefits of

turning waste into wealth, preservation of environment, job creation as well as opening up opportunity for designing smart materials with predetermined mechanical properties.

Paulo Pecas et al [18] "Natural Fiber Composites and Their Applications" A bibliometric study regarding applications of natural fibers composites and the prospective analysis about the future trends of natural fibers applications and the required developments to broaden their applications is also presented. The recycling, social influence and changing cognitive values in the composition of natural fibers are discussed in this paper.

Jena Pandey et al [19] "Comparison of jute fiber over glass fiber and carbon fiber reinforced plastic material composites used for civil structure". In this paper Jute textile reinforced polymer composite system was developed and its tensile, flexural behaviour was characterized and compared with that of carbon textile (CFRP) and glass textile (GFRP) reinforced polymer composite. In the present work the efficacy of jute textile reinforced polymer composite (JFRP) as compared to CFRP and GFRP for the flexural strengthening of reinforced concrete beams. The work carries out the study of failure modes, flexural strengthening effect on ultimate load and load deflection behaviour as well as the deflection ductility study of RC beams bonded externally with JFRP, CFRP and GFRP, wrapped in U configuration in single layer, along the entire length of the beam in full wrapping and strip wrapping technique.

J. Gassan et al [20] "Composites reinforced with cellulose based fibers". This article concerning natural and man-made cellulose fiber reinforced plastics, introduces possible applications and having physical properties that are mainly determined by the chemical and physical composition, such as the structure of fibers, cellulose content, angle of fibrils, cross-section, and by the degree of polymerization. The specific mechanical properties, can reach comparable values of traditional reinforcing fibers and it can be modified by using alkali treatment and acetylation processes.

Satish Pujari et al [21] "Comparison of Jute and Banana Fiber Composites". The present review explores the potentiality of jute and banana fiber composites, emphasizes both mechanical and physical properties and their chemical composition. Combining the useful properties of two different materials, cheaper manufacturing cost, versatility, availability makes them useful in various fields of engineering and high-performance applications.

Tara Sen et al [22] "Pretreatment of Woven Jute FRP Composite and Its Use in Strengthening of Reinforced Concrete Beams in Flexure" Evaluating the mechanical characteristics of natural woven jute fiber reinforced polymer (FRP) composite subjected to three different pretreatments, alkali, benzyl chloride, and heat treatment. It concludes that heat treatment is one of the most suitable treatment methods for enhancing mechanical properties of jute FRP such as high tensile strength, ultimate flexural strength and good ageing characteristics.

J Naveen et al [23] "A review of GFRP composites". The mechanical, tribological, thermal, water absorption, vibrational properties, strength, flexibility, stiffness, resistance to chemical harm and applications of various glass fiber reinforced polymer composites were reported.

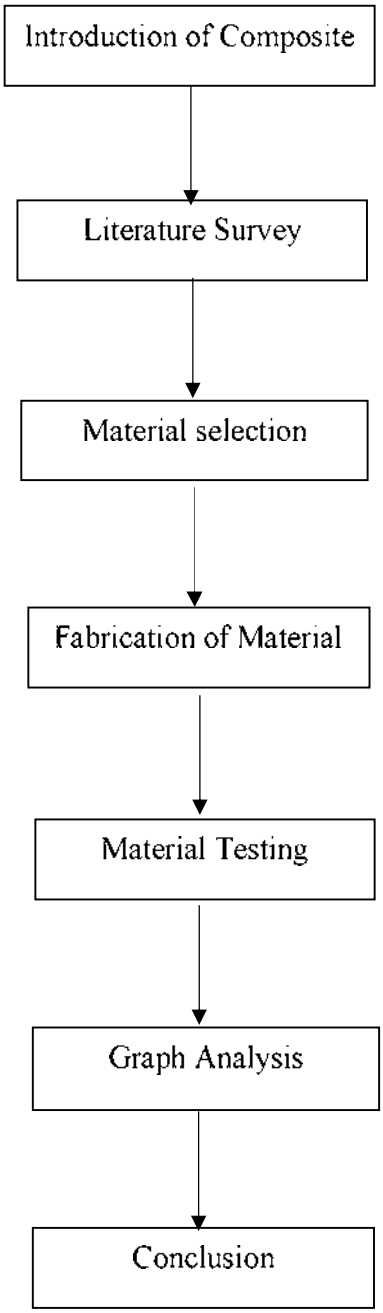
I.S.N.V.R.Prasanth et al [24] "Experimental investigation on comparison of the surface quality on various GFRP composites during end milling by control process parameters". The effect of process parameters on the dimensional accuracy, surface finish and damages of the slots produced by end milling on GFRP composite laminate needs machining to obtain close dimensional accuracy with minimized surface damages towards the selection of best milling processes parameters such as spindle speed, feed rate and depth of cut. The investigation results pertaining to resultant force, surface roughness and delamination aspects of uni- directional (UD) and bi-directional (BD) glass fiber reinforced composite laminates are the important aspect in production industries such as automobile, aerospace and other industrial applications were discussed.

J. Sahari et al [25] "Natural Fiber Reinforced Bio-Degradable Polymer Composites" The production and properties of bio composites are the polymer matrices derived from renewable resources such as poly lactide (PLA), thermoplastic starch (TPS), cellulose and poly hydroxy alkenoates (PHAs). This review is carried out to evaluate the development and properties of natural fiber reinforced biodegradable polymer composites having the capability to fully degrade and compatible it with the environment.

Sreenivasulu Reddy et al [26] "Aero Space Applications of GFRP Composites". The surface quality and dimensional precision greatly affect the parts during their useful life, especially in cases where the components come in contact with other elements or materials.

CHAPTER 3

METHODOLOGY



CHAPTER 4

SELECTION OF MATERIALS AND FABRICATION

We have selected **Jute fiber reinforced polymer** material as a **natural composite** and **Glass fiber reinforced polymer** material as an **artificial composite**. For material testing we have fabricated the material for certain dimensions to gain accuracy.

4.1 SPECIMEN SIZE

- Tensile test

  JFRP – 250 mm **X** 25 mm **X**3 mm

  GFRP - 250 mm **X** 25 mm **X**3 mm

- Bending test

  JFRP - 150 mm **X** 25 mm **X**3 mm

  GFRP - 150 mm **X** 25 mm **X**3 mm

- Fatigue test

  JFRP - 250 mm **X** 25 mm **X**3 mm

  GFRP - 250 mm **X** 25 mm **X**3 mm

- Shear test

  JFRP - 250 mm **X** 25 mm **X**3 mm

  GFRP - 250 mm **X** 25 mm **X**3 mm

4.2 FABRICATION PROCEDURE

Vacuum assisted resin infusion molding technique was used for manufacturing specimens. Fiber reinforced composite materials are orthotropic materials which generally show different characteristics in fiber, matrix and through thickness direction.

These characteristics may depend on fiber material, matrix material, fiber orientation etc.Different apparatus configurations were used for shear, tension and compression strength values.

The various steps involved in the vacuum assisted resin infusion molding panel fabrication technique are as listed below,

STEP 1

Prepare the required flat surface as necessary.

Fig No: 4.1 Flat Surface

STEP 2

Bonding surfaces must be free of any contaminants such as grease, oil, wax or mold release. Clean contaminated surfaces with lacquer thinner, acetone or other appropriate solvent. Wipe the surface with paper towels before the solvent dries. Clean surfaces before sanding to

avoid sanding the contaminant into the surface. Follow all safety precautions when working with solvents.

Fig No: 4.2 Wrapping Sheet

STEP 3

Prepare the vacuum bagging materials such as Cut carbon fabric, perforated releasing film, bagging film, peel ply and breather slightly larger than the fabric area. Cut the vacuum bag several inches larger on all sides than the working area. Apply sealant of 1/2 inches outside the perimeter of the working area.

Fig No: 4.3 Sealant Tape Pasting

STEP 4

Mix required resin/hardener as you can apply during the open time of the mixture. Pour the mixture into a roller pan as soon as it is mixed thoroughly.

Fig No: 4.4 Resin Application

STEP 5

Wet out the fabric area with a resin/hardener mixture. Apply a thin layer of thickened phenolic resin mixture to the fabric area to fill voids or unevenness and removing air bubbles and excess resin. Surface finishing is a broad range of industrial processes that alter the surface of a manufactured item to achieve a certain property.

Finishing processes may be employed to improve appearance, adhesion or wettability, solderability, corrosion resistance, tarnish resistance, chemical resistance, wear resistance, hardness, modify electrical conductivity, remove burrs and other surface flaws, and control the surface friction. In limited cases some of these techniques can be used to restore original dimensions to salvage or repair an item. An unfinished surface is often called mill finish.

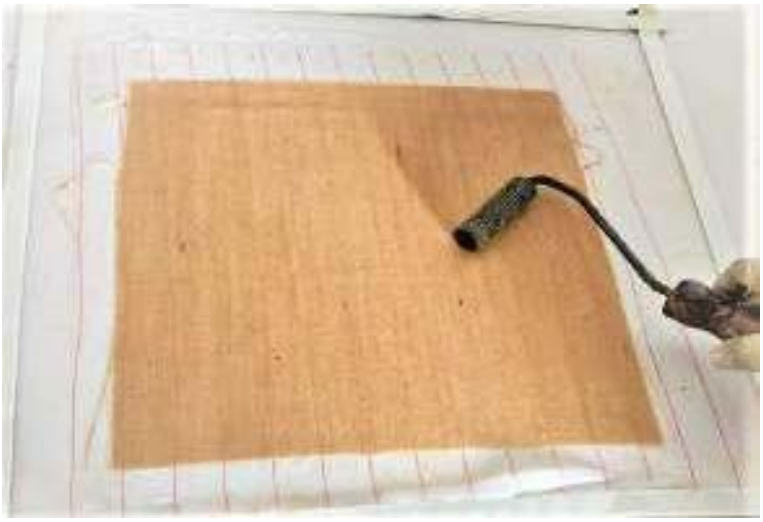


Fig No: 4.5 Jute Fabric Cloth

STEP 6

Squeegee the layer of release fabric over the layers of cloth to remove any trapped air and excess Phenolic. Place the peel ply, perforated film and breather material over the lay-up and seal the vacuum bag to the sealant tape.

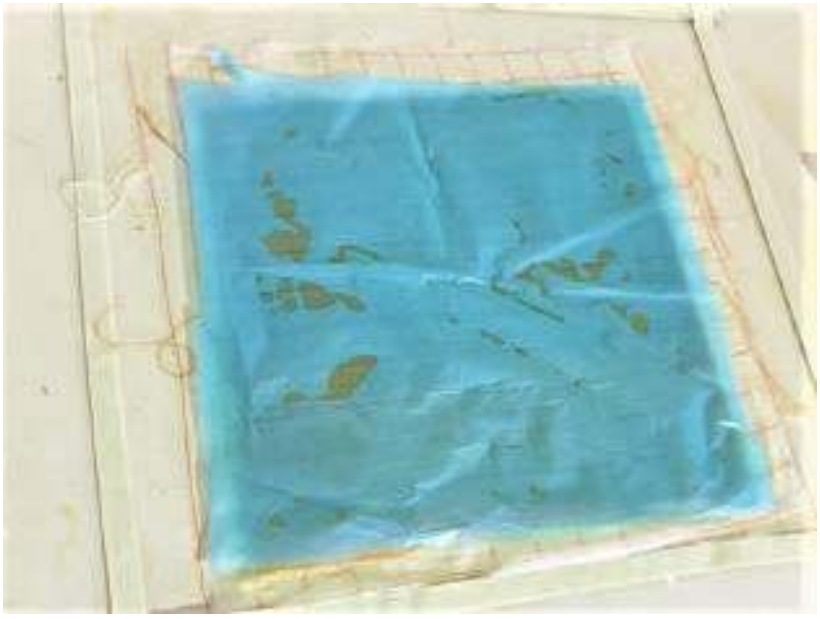

Fig No: 4.6 Perforated Film

STEP 7

Attach the vacuum port off to the side of the working area if possible, to avoid dimpling the fabric with the vacuum port.

Fig No: 4.7 Sponge for curing

STEP 8

Turn on the vacuum pump and attach the vacuum gauge. After the vacuum has stabilized, moderate heat from a heat lamp or portable heater may be applied to the lay-up to speed the cure. Allow the lay-up to cure thoroughly and remove the bag, breather, perforated film and release fabric.

There are various methods of curing. The adoption of a particular method will depend upon the nature of work and the climatic conditions. The following methods of curing of concrete are generally adopted.

Fig No 4.8 Vacuum resin molding

STEP 9

Finally, the material had been cut down by using water jet method to avoid delamination for our own desired sizes. Thus, the material had been fabricated.

Fig No: 4.9 Specimen for Testing

CHAPTER 5

TESTING OF MATERIALS

Structural applications are applications that require mechanical performance (e.g., strength, stiffness and vibration damping ability) in the material, which may or may not bear the load in the structure. The material does bear the load, the mechanical property requirements are particularly stringent. In addition to mechanical properties, a structural material may be required to have other properties, such as low density (i.e., be lightweight) for to save fuel in the case of aircraft and automobiles, to facilitate high speed in the case of race bicycles, and for easier handling in the case of wheelchairs and armor.

Another property that is often required is corrosion resistance, which is desirable for the durability of all structures, particularly automobiles and bridges. Yet another property that may be required is the ability to withstand high temperatures and/or thermal cycling, as heat may be encountered by the structure during operation, maintenance or repair.

In this project, we have performed various testing of both Jute and GFRP materials to determine its mechanical behaviour. There are four testing that we have performed namely,

- Tensile Testing
- Fatigue Testing
- Shear Testing
- Bending Testing

5.1 TENSILE TESTING

Tensile testing is also known as tension testing. It is a fundamental materials science and engineering test in which a sample is subjected to a controlled tension until failure. Properties that are directly measured via a tensile test are ultimate tensile strength, breaking strength, maximum elongation and reduction in area.

From the above measurements various properties canbe determined namely Young's modulus, Poisson's ratio, yield strength, and strainhardening characteristics. Uniaxial tensile

testing is the most commonly used for obtaining the mechanical characteristics of isotropic materials. Some materials use biaxial tensile testing.Tensile testing might have a variety of purposes which are as follows,

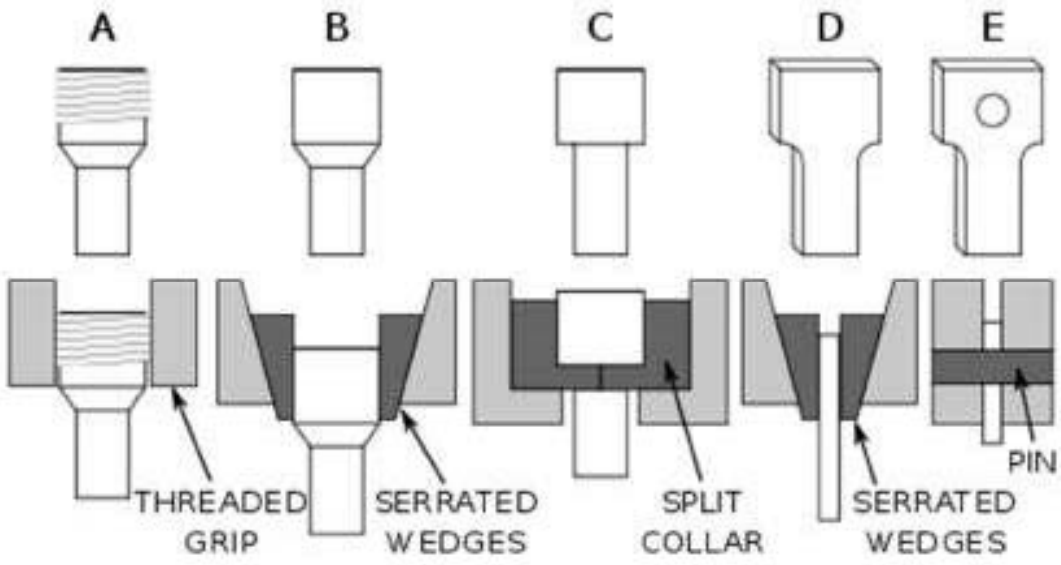
- Select a material or item for an application.
- Predict how a material will perform under normal and extreme forces.
- Determine or verify the requirements of a specification, regulation, or contraction in that specimen.
- Decide if a new product development program is on track.
- Demonstrate proof of concept.
- Demonstrate the utility of a proposed patent.
- Provide standard data for other scientific, engineering ,and quality assurance functions
- Provide a basis for Technical communication
- Provide a technical means of comparison of several options
- Provide evidence in legal proceedings

The preparation of test specimens depends on the purposes of testing and on the governing test method or specification. A tensile specimen is usually a standardized sample cross-section. It has two shoulders and a gage in between.

The shoulders are large so they can be readily gripped, whereas the gauge section has a smaller cross-section so that the deformation and failure can occur in this area.

The shoulders of the test specimen can be manufactured in various ways to mate to various grips in the testing machine. Each system has advantages and disadvantages; for example, shoulders designed for serrated grips are easy and cheap to manufacture, but the alignment of the specimen is dependent on the skill of the technician. On the other hand, a pinned grip assures good alignment.

Threaded shoulders and grips also assure good alignment, b ut the technician must know to thread each shoulder into the grip at least one diameter's length, otherwise the threads can strip before the specimen fractures.



Where,

A	Threaded shoulder for use with a thread
B	Round shoulder for use with serrated grips
C	Butt end shoulder for use with a split collar
D	Flat shoulder for used with serrated grips
E	Flat shoulder with a through hole for a pinned grip

Fig No 5.1 Various shoulder styles for tensile specimens.

The most common testing machine used in tensile testing is the universal testing machine. This type of machine has two crossheads; one is adjusted for the length of the specimen and the other is driven to apply tension to the test specimen. There are two types: hydraulic powered and electromagnetically powered machines.

The machine must have the proper capabilities for the test specimen being tested. There are four main parameters: force capacity, speed, precision and accuracy. Force capacity refers to the fact that the machine must be able to generate enough force to fracture the specimen. The machine must be able to apply the force quickly or slowly enough to properly mimic the actual

application. Finally, the machine must be able to accurately and precisely measure the gauge length and forces applied; for instance, a large machine that is designed to measure long elongations may not work with a brittle material that experiences short elongations prior to fracturing.

Alignment of the test specimen in the testing machine is critical, because if the specimen is misaligned, either at an angle or offset to one side, the machine will exert a bending force on the specimen. This is especially bad for brittle materials, because it will dramatically skew the results. This situation can be minimized by using spherical seats or U-joints between the grips and the test machine. If the initial portion of the stress–strain curve is curved and not linear, it indicates the specimen is misaligned in the testing machine. The strain measurements are most commonly measured with an extensometer, but strain gauges are also frequently used on small test specimen or when Poisson's ratio is being measured.

Fig No: 5.2 Tensile Test

The test process involves placing the test specimen in the testing machine and slowly extending it until it fractures. During this process, the elongation of the gauge section is recorded against the applied force.

5.2 FATIGUE TESTING

Fatigue testing is a specialized form of mechanical testing that is performed by applying cyclic loading to a coupon or structure. These tests are used either to generate fatigue life and crack growth data, identify critical locations or demonstrate the safety of a structure that may be susceptible to fatigue. Fatigue tests are used on a range components from coupons through to full size test articles such as automobiles and aircraft.

Fatigue tests on coupons are typically conducted using servo hydraulic test machines which are capable of applying large variable amplitude cyclic loads. Constant amplitude testing can also be applied by simpler oscillating machines.

The fatigue life of a coupon is the number of cycles it takes to break the coupon. This data can be used for creating stress-life or strain-life curves. The rate of crack growth in a coupon can also be measured, either during the test or afterward using fractography. Testing of coupons can also be carried out inside environmental chambers where the temperature, humidity and environment that may affect the rate of crack growth can be controlled.

Because of the size and unique shape of full size test articles, special test rigs are built to apply loads through a series of hydraulic or electric actuators. Actuators aim to reproduce the significant loads experienced by a structure, which in the case of aircraft, may consist of maneuver, gust, buffet and ground-air-ground (GAG) loading.

A representative sample or block of loading is applied repeatedly until the safe life of the structure has been demonstrated or failures occur which need to be repaired. Instrumentation such as load cells, strain gauges and displacement gauges are installed on the structure to ensure the correct loading has been applied. Periodic inspections of the structure around critical stress concentrations such as holes and fittings are made to determine the time detectable cracks were found and to ensure any cracking that does occur, does not affect other areas of the test article. Because not all loads can be applied, any unbalanced structural loads are typically reacted out to the test floor through non-critical structure such as the undercarriage.

Fatigue tests are used to obtain material data such as the rate of growth of a fatigue crack that can be used with crack growth equations to predict the fatigue life. These tests usually determine the rate of crack growth per cycle versus the stress intensity factor range .

Standardized tests have been developed to ensure repeatability and to allow the stress intensity factor to be easily determined . Strain gauges are used to monitor the applied loading or stress fields around the crack tip. They may be placed beneath the path of the crack or on the back face of a compact tension coupon.

- An extensometer or displacement gauge can be used to measure the crack tip opening displacement at the mouth of a crack. This value can be used to determine the stress intensity factor which will change with the length of the crack. Displacement gauges can also be used to measure the compliance of a coupon and the position during the loading cycle when contact between the opposite crack faces occurs in order to measure crack closure.
- Applied test loads are usually monitored on the test machine with a load cell.
- A travelling optical microscope can be used for measurement of the position of the crack tip. In order to apply the correct loads to various parts of the structure, a mechanism known as a whiffle tree is used to distribute the loads from a loading actuator to the test article. Loads applied to a central point are distributed through a series of pin jointed connected beams to produce known loads at the end connections. Each end connection is typically attached to a pad which is bonded onto the structure such as an aircraft wing. Hundreds of pads are usually applied to reproduce the aerodynamic and inertial loads seen on wing. Because the whiffle tree consists of tension linkages, they are unable to apply compressive loads and therefore, independent whiffle trees are typically used on the upper and lower sides of wing fatigue tests.
- Hydraulic, electromagnetic or pneumatic actuators are used to apply loads to the structure, either directly or through the use of a whiffle tree to distribute the loads. A load cell is placed in line with the actuator and is used by the load controller to control the loads into the actuator. When many actuators are used on a flexible test structure, there may be cross-interaction between the different actuators. The load controller must ensure that spurious loading cycles are not applied to the structure as a result of this interaction.

- Many of the loads such as aerodynamic and internal forces are re-acted by internal forces which are not present during a fatigue test. Hence, the loads are reacted out of the structure at non-critical points such as the undercarriage or through restraints on the fuselage.
- Linear variable differential transformer can be used to measure the displacement of critical locations on the structure. Limits on these displacements can be used to signal when a structure has failed and to automatically shut down the test.
- Some test structure may be expensive or unavailable and are typically replaced on the test structure with an equivalent structure. Structure that is close to actuator attachment points may see an unrealistic load that makes these areas non-representative.

Fig No: 5.3 Fatigue Test

5.3 SHEAR TEST

A shear test is designed to apply stress to a test sample so that it experiences a sliding failure along a plane that is parallel to the forces applied. Generally, shear forces cause one surface of a material to move in one direction and the other surface to move in the opposite direction so that the material is stressed in a sliding motion. Shear tests differ from tension and compression tests in that the forces applied are parallel to the two-contact surface, whereas, in tension and compression they are perpendicular to the contact surfaces.

The most common use of a shear test is to determine the shear strength, which is the maximum shear stress that the material can withstand before failure occurs, of a material. This is a very important design characteristic of many types of fasteners such as bolts and screws. For example, when a bolt is used to secure two plates together it will experience a shear forces if the plates themselves experience any forces parallel to their plane that attempt to separate them. If the small fastener fails in shear it may lead to a chain of failures that could lead to the entire destruction of a much larger structure.

Generally, there are two common types of shear tests. The first requires that the sample be setup in a modified three-point flexure or four-point bend fixture. The purpose of this test is to load the sample so that it experiences double shear or so that the sample has two locations where the forces are applied. Each end of the sample is anchored and the force is applied over the middle of the sample in an attempt to remove the middle section so that both ends are left behind. The second test requires that the sample have tapered ends that are each placed into grip fixtures that have been offset from the vertical axis of the sample. The sample is then pulled so that the opposite faces are pulled in opposing directions.

Three materials are commonly tested in shear such as rigid substrates, adhesives, and layered composites. Rigid substrates may be composed of metals, plastics, ceramics, composites or woods but usually come in a solid form and are used as building materials or fasteners. Adhesives are used to bond two materials together and experience shear stress when the materials are pulled in opposing directions in an attempt to slide them apart. Layered composites experience shear stress in a similar manner to adhesives as the shear forces are applied to the glue or laminate used to hold the layers together.

Shear tests are generally carried out to measure the ability of an adhesive tape to resist creep under a constant load, applied parallel to the surface of the tape and substrate. The purpose of this test is to compare the performance of an adhesive in a joint and to determine its mechanical response.

Fig No: 5.4 Shear Test

5.4 BENDING TESTING

The bend test is a simple and inexpensive qualitative test that can be used to evaluate both the ductility and soundness of a material. It is often used as a quality control test for butt-welded joints, having the advantage of simplicity of both test piece and equipment.

No expensive test equipment is needed, test specimens are easily prepared and the test can be carried out on the shop floor as a quality control test to ensure consistency in

production.The bend test uses a coupon that is bent in three-point bending to a specified angle.The outside of the bend is extensively plastically deformed so that any defects in, or embrittlement of, the material will be revealed by the premature failure of the coupon.The bend test may be free formed or guided.The guided bend test is where the coupon is wrapped around a former of a specified diameter and is the type of test specified in the welding procedure and welder qualification specifications.For butt weld procedure and welder qualification testing the bend coupons may be oriented transverse or parallel to the welding direction.

Where the material thickness is too great to permit the full section to be bent the specifications allow a number of narrower specimens to be taken provided that the full material thickness is tested. Conventionally, most welding specifications require two root and two face bend coupons or four side bends to be taken from each butt -welded test piece.

Fig No: 5.5 Bending Test

The transverse face bend specimen will reveal any defects on the face such as excessive undercut or lack of sidewall fusion close to the cap. The transverse root bend is also excellent at revealing lack of root fusion or penetration. The transverse side bend tests the full weld thickness and is particularly good at revealing lack of side-wall fusion and lack of root fusion in double-V butt joints. This specimen orientation is also useful for testing weld cladding where any brittle regions close to the fusion line are readily revealed.

Weld joints with non-uniform properties such as dissimilar metal joints or where the weld and parent metal strengths are substantially different can result in 'peaking' of the bend coupon. This is when most of the deformation takes place in the weaker of the two materials which therefore experiences excessive localized deformation that may result in premature failure.A dissimilar metal joint where one of the parent metals is very high strength is a good example of where this may occur and similar peaking can be seen in fully hard welded aluminium alloy joints.

CHAPTER 6

RESULT AND GRAPH ANALYSIS

The result and analysis of graph for both Jute and GFRP composite materials are discussed in this chapter.

CHAPTER 7

CONCLUSION

The Jute and GFRP composites are successfully fabricated under specific dimensions by using Vacuum assisted epoxy resin infusion manufacturing technique and subjected to Tensile, Fatigue, Shear and Bending tests respectively. On following the results of testing, comparative graphs are drawn to analyse the material behaviour of composites easily

In this research, the mechanical characterization and behavioral analysis of both Natural (JUTE) and Artificial (GFRP) fiber laminated in epoxy resin composites are studied.

The load carrying capacity of these composites are very less. In future, reinforcement of composite materials can be done to increase the load carrying capacity. The work may be extended by analyzing the corrosion and thermal resistant of this material so that, it may find more applications. By changing the type of resin, the application may be extended to prepare bio-degradable and eco-friendly composite materials for different applications. These samples are further treated for Compressive test, Fracture toughness test, Creep test, Water absorption test etc.,

One of the major problems associated with the use of natural fibers in composites is their high moisture sensitivity leading to severe reduction of mechanical properties and delamination. The reduction in mechanical properties may be due to poor interfacial bonding between resin matrices and fibers. It is therefore necessary to modify the fiber surface to render it more hydrophobic and also more compatible with resin matrices. An effective method of chemical modification of natural fibers is graft copolymerization. The resulting co-polymer displays the characteristic properties of both fibrous cellulose and grafted polymer. It will enrich the mechanical properties of both natural (Jute) and artificial (GFRP) composites.

ABSTRACT: The composite materials are replacing the traditional materials, because of its superior properties such as high tensile strength, low thermal expansion, high strength to weight ratio. Natural fiber composites such as sisal and jute polymer composites became more attractive due to their high specific strength, lightweight and biodegradability. Artificial composites such as Glass Fiber Reinforced Polymer, Carbon Fiber Reinforced Polymer having high strength, durability and non-biodegradability.

In this study, both the Natural (Jute fiber) and Artificial Composites (GFRP) are developed and their mechanical properties such as tensile strength, compression strength, bending test, fatigue strength, shear strength and impact strength are evaluated. The interfacial properties, internal cracks and internal structure of the fractured surfaces are evaluated.

INTRODUCTION: A composite is a structural material that consists of two or more combined constituents that are combined at a macroscopic level and are not soluble in each other. Composite materials are multiphase materials obtained through the artificial combination of different materials in order to attain properties that the individual components by themselves cannot attain. One constituent is called the reinforcing phase and the one in which it is embedded is called the matrix. The reinforcing phase material may be in the form of fibers, particles, or flakes. The matrix phase materials are generally continuous. Examples of composite systems include concrete reinforced with steel and epoxy reinforced with graphite fibers, etc. If the composition occurs on a microscopic scale (molecular level), the new material is then called an alloy for metals or a polymer for plastics.

ANALYSIS AND EFFECT OF SHIM USED IN A COMPOSITED AND METAL BOLTED JOINT

ABSTRACT

This paper about the behaviour of joints, that most of the composites can't be riveted. Mostly bonding (adhesives) technique is used to join the two different materials, like metal to composites and composites-composites. Our work is to address the behaviour (strength and life time) of different composite and metal joints using FEA analysis. Which will reduce the time and cost of the testing. There are different techniques (from literature) which have been considered and by using different thickness layer of shim with bolted joints in the composite material and compare the results with the test results.

CHAPTER 1

INTRODUCTION

Composite materials are being extensively used in an aircraft manufacturing industry. The property of weight reduction is the main driving force which benefits fatigue and corrosion resistance properties. A clear trend in composites is being increasing with in heavily loaded primary structures. The increasing use of Composite materials and its popularity has prompted significant changes in the field of research and developing for reliable design methods. Designing useful structures requires several parts to be joined together. This can be done only by adhesive, mechanical or hybrid joins which is a combination of the first two techniques. With low weight and good sealing properties the adhesive joints have advantage over the mechanical joints. The adhesive joints are sensitive to environmental conditions and adhesive structures cannot be easily replaced when few parts get damaged. Mechanical joining, i.e. using fasteners, is the most common method in an aerospace industry. Although it's most preferred in most of the cases it's associated with difficulties. The presence of a hole in the laminate disturbs the stress field because stresses are concentrated at the vicinity of the hole. This makes the bolted joint as a weak link in the composite structure, which materials

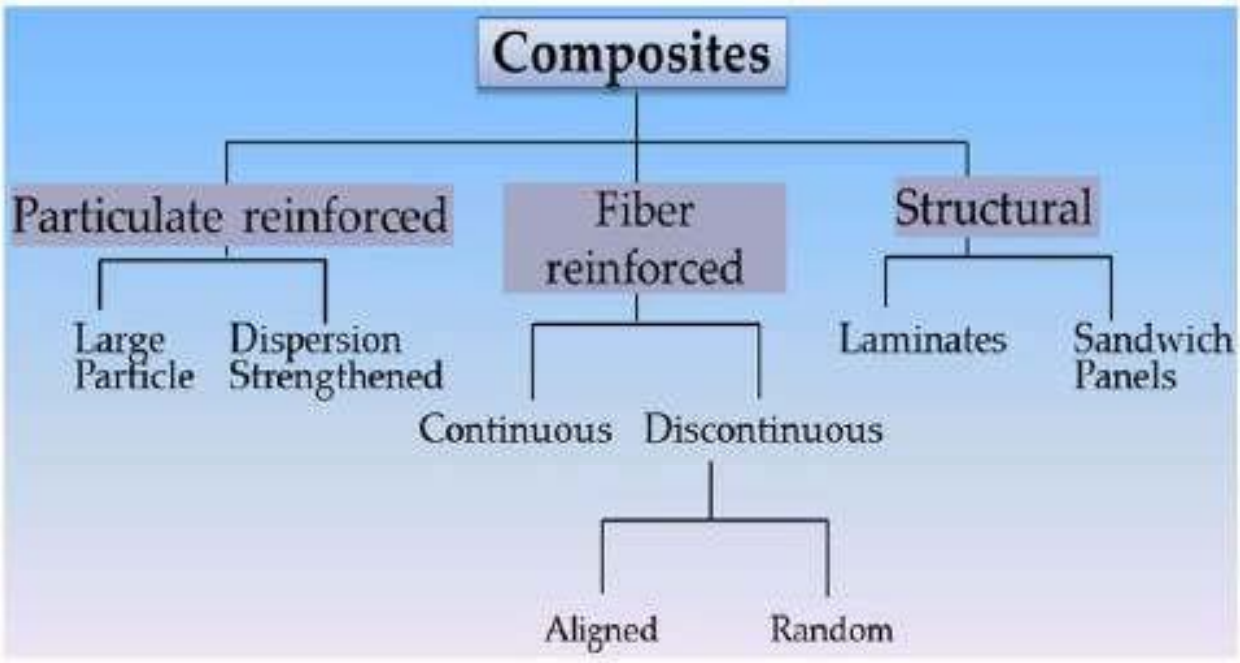

Fig 1.1 Classification of composites

1.1 CLASSIFICATION

Most composite materials developed thus far have been fabricated to improve mechanical properties such as strength, stiffness, toughness, and hightemperature performance. It is natural to study together the composites that have a common strengthening mechanism. The strengthening mechanism strongly depends on the geometry of the reinforcement. Therefore, it is quite convenknt to classify composite materials on the basis of the geometry of a representative unit of reinforcement.

1.2 PARTICULATE COMPOSITES

A composite whose reinforcement may be classified as particles is called a particulate composite. A particle, by definition, is nonfibrous and generally has no long dimension, with the exception of platelets. The dimensions of the reinforcement determine its capability of contributing its properties to the composite. Also, a reinforcement having a long dimension discourages the growth of incipient crack normal to the reinforcement that otherwise might lead to failure, particularly with brittle matrices. Therefore, fibers are very effective in improving the fracture resistance of the matrix. In general, particles are not very effective in improving fracture resistance. However, particles of rubberlike substances in brittle polymer matrices improve fracture resistance by promoting and then arresting crazing in the brittle matrices.

Other types of particles, such as ceramic, metal, or inorganic particles, produce reinforcing effects in metallic matrices by different strengthening mechanisms The particles in a particulate composite place constraints on the plastic deformation of the matrix material between them because of their inherent hardness relative to the matrix. The particles also share the load, but to a much smaller extent than those fibers in fibrous composites that lie parallel to the direction of load. Thus the particles are effective in enhancing the stiffness of the composites but do not offer the potential for much strengthening.

For example, hard particles placed in brittle matrices reduce the strength due to stress concentrations in the adjacent matrix material. Particle fillers, however, are used widely to improve the properties of matrix materials, such as to modify the thermal and electrical conductivities, improve performance at elevated temperatures, reduce friction, increase wear and abrasion resistance, improve machinability, increase surface hardness, and reduce shrinkage. In many cases they are used simply to reduce cost. The particles and matrix material in a particulate composite can be any combination of metallic and nonmetallic materials. The choice of a particular combination depends on the desired end properties. Particles of lead are mixed with copper alloys and steel to improve their machinability. In addition, lead is .a natural lubricant in bearings made of copper alloys. Particles of many brittle metals such as tungsten, chromium, and molybdenum .are incorporated into' ductile metals to improve their elevated temperature performance while maintaining ductile characteristics at room temperature. Composites with parttticles of tungsten, molybdenum, or their carbides in silver and copper matrice are used widely for electrical-contact applications. These applications requil materials with properties such as high thermal and electrical conductivitie: high melting point, and low friction and wetting characteristics. These m, terials are also used for electrodes and related applications in the weldin industry.

It is well known that the measured strengths of most materials are found to be much smaller (by a couple of orders of magnitude) than their theoretical strengths. The discrepancy in strength values is believed to be due to the presence of imperfections or inherent flaws in the material. An attempt to minimize or eliminate flaws enhances the strength of a material. Flaws in the form of cracks that lie perpendicular to the direction of applied loads are particularly detrimental to strength. Therefore, compared with the strength of the bulk material, man-made filaments or fibers of non polymeric materials exhibit much

higher strengths along their lengths because large flaws that may be present in the bulk material are minimized owing to the small cross sectional dimensions of the fiber. In the case of polymeric materials, orientation of the molecular structure is responsible for high strength and stiffness.

Properties of some common types of fibers as well as some conventional materials are given in, which clearly shows the importance of fibers in achieving higher strengths. The high strength of glass fibers is attributed to a defect-free surface, whereas graphite and aramid fibers attain their strength as a result of improved orientation of their atomic or molecular structure. The most important reinforcement fiber is E-glass because of its relative low cost. However, boron, graphite, and the aramid polymer fibers (Kevlar49) are most exceptional because of their high stiffness values. Of these, thegraphite fibers offer the greatest variety because of the ability to control their structure. Fibers, because of their small cross-sectional dimensions, are not directly usable in engineering applications. They are, therefore, embedded in matrix materials to form fibrous composites. The matrix serves to bind the fibers together, transfer loads to the fibers, and protect them against environmental attack and damage due to handling. In discontinuous fiber-reinforced composites, the load-transfer function of the matrix is more critical than in continuous-fiber composites. The fibrous composites have become the most important class of composite materials because they are capable of achieving high strengths.

APPLICATIONS OF FIBER COMPOSITES

The two outstanding features of oriented-fiber composites are their high strength-weight ratio and contrQlled anisotropy. The strength and modulus of commonly used bidirectional composites are compared with those of conventional structural materials strengths and moduli approximately one-half of those of unidirectional laminates. They have equal properties in two principal directions and show smaller property. variation with direction. Fiber composites generally are superior to metals with respect to specific strength and modulus. However, glass-fiber composites are inferior to both steel and aluminum with respect to specific modulus. In applications where the structure's weight is a factor in the design, comparisons should be made on the basis of specific properties of the materials.

Controlled anisotropy means that the ratio of property values in different directions can be varied or controlled. For example, in a unidirectional composite, l >P. longitudinal strength-transverse strength ratio can be changed easily by changing the fiber volume fraction. Similarly, other properties can be altered by altering the material and manufacturing variables. Further, laminates are designed and constructed from unidirectional composites to obtain desired directional properties to match requirements of specific applications.

These two features, high specific strength and controlled anisotropy, make fiber composites very attractive structural materials. Their other advantages include ease of manufacture and structural forms that are otherwise inconvenient or impossible to manufacture. Their use, therefore, in aerospace and transportation industries is increasing continuously. Fiber-reinforced polymer matrix composites are the most widely used fiber composites. The U.S. polymer composite industry has grown at an average rate of 6.5% since 1960, which is approximately twice the growth rate of the U.S. economy. U.S. growth in composites is compared with that of steel.

ADVANCED FIBERS

A great majority of materials are stronger and stiffer in the fibrous form than as a bulk material. A high fiber aspect ratio (length-diameter ratio) permits very effective transfer of load via matrix materials to the fibers, thus taking advantage of their excellent properties. Therefore, fibers are very effective and

attractive reinforcement materials. Reinforcing fibers used in advanced composites are discussed in this section.

Glass fibers are the most common of all the reinforcing fibers for polymer matrix composites. The principal advantages of glass fibers are the low cost and high strength. However, glass fibers have poor abrasion resistance, which reduces their usable strength. They also exhibit poor adhesion to some polymer matrix resins, particularly in the presence of moisture. To improve adhesion, the glass fiber surface often is treated with chemicals called coupling agents (mostly silanes).

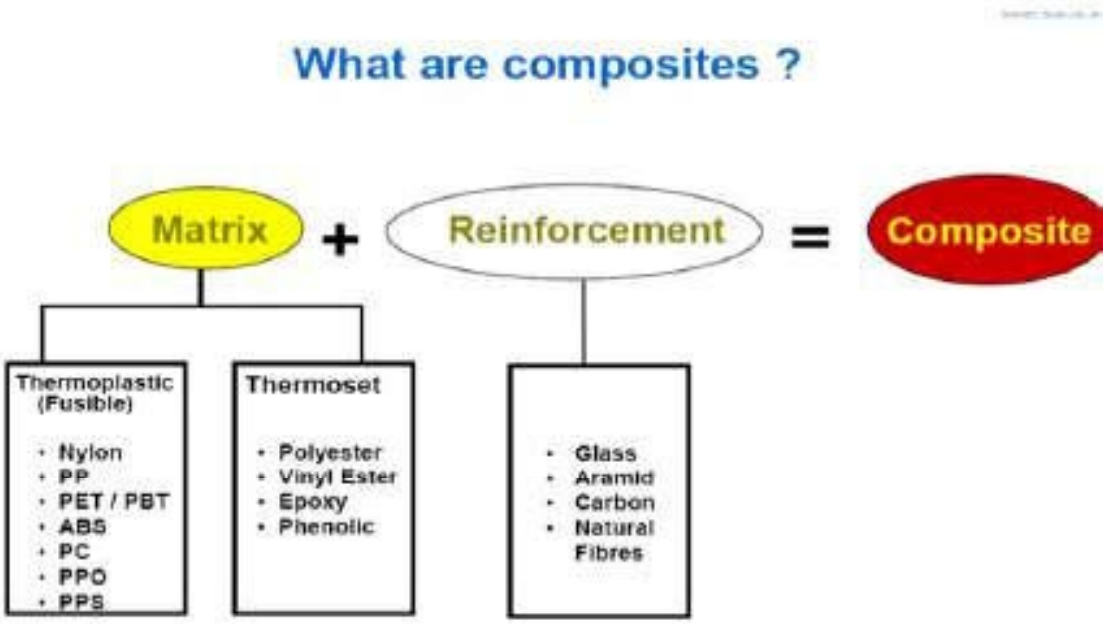

Fig 1.2 properties of composites

Two forms of fiberglass can be produced- continuous fiber and staple (discontinuous) fiber. Both forms are made by the same production method up to the fiber-drawing stage. Ingredients such as sand, limestone, and alumina are dry-mixed and melted in a refractory furnace. The temperature of the melt varies for each glass composition but generally is about 1260°C. The molten glass flows directly.

Into the fiber-drawing furnace in the direct-melt process or flows into a marble-making machine in the. marble process. The marbles are subsequently remelted and drawn into fibers. Most fiberglass is currently produced by the direct-melt process, illustrated schematically.

Continuous fibers are produced by introducing molten glass into a platinum bushing, where the molten glass is gravity-fed through a multiplicity of holes in the base of the bushing. The molten glass exits from each orifice and is gathered together and attenuated mechanically to the proper dimensions, passed through a light water spray (quench), and then traversed over a belt that applie's a protective and lubricating binder or size to the individual fibers. These fibers then are gathered together into a bundle of fibers called a strand or end. The fiberglass strand, typically consisting of 204 filaments, is then wound onto a receiving package (spool) at speeds of up to 50 mis. This "cake" is then conditioned or dried prior to further processing into other textile forms.

Glass fibers are amorphous solids. Chemically, glass is composed primarily of a silica (Si02) backbone in the form of (-Si04-)n tetrahedra. Modifier ions are added for their contribution to glass properties and manufacturing capability. For structural composites, the two commonly used types of glass fiber are E-glass and S-glass. Compositions of these are given and some important properties. At present, E-glass constitutes the majorityof glass-fiber production.

Sizes and Coupling Agents The chemical treatments applied during the forming of glass fibers are called sizes.These are of two general types: temporary sizes and compatible sizes.The temporary sizes are applied to minimize the degradation of strength resulting from abrasion of fibers against one another and to bind the fibers together for easy handling in forming woven (twisting and weaving) glassfiber products. These sizes are often starch-oil sizes. Ingredients of starch-oil sizes interfere with good bonding between the fibers and impregnating resin. Oil, emulsifying agent, and lubricant prevent good fiber wetting by the resin, and the starch, gelatin, and polyvinyl alcohol result in high water absorption and poor fiber-resin adhesion in the presence of moisture. Sizes of this type must be removed and replaced by a finish (coupling agent) before the fibers can be impregnated with resin. The sizes are easily removed by heating the fibers in an air-circulating oven at 340°C or higher temperatures for 15-20 h. Forms of Glass Fiber Glass fibers are commercially available in various forms suitable for different applications. Some of them are described in the following paragraphs and are illustrated in the photographs .

Fiberglass roving is a collection of parallel continuous ends of filaments. Conventional rovings are produced by winding together the number of single strands necessary to achieve the desired yiekl (number ofmeters of roving per kilogram of weight). Generally, rovings are made with fibers of diameter 9 or 13 μm. Roving yields vary from about %00 to 450 m/kg and typically have 20 strands. Rovings are used directly in pultrusion, filament winding, and prepreg manufacture.

Carbon/ graphite fibers are the predominant high-strength, high-modulus reinforcement used in th fabrication of high-performance polymer-matrix composites. Their use is growing rapidly owing to a significant reduction in their price in the 1990s and an increase in their availability. Besides aerospace applications, they are now being u,sed in sporting goods, automotive, civil infrastructure, offshore oil, and mahy other consumer applications.

In the graphite structure, the carbon atoms are arranged in the form of hexagonal layers with a very dense packing in the layer planes. The highstrength bond between carbon atoms in the layer plane results in an extremely high modulus, whereas the weak van der Waals-type bond between the neighboring

Layers results in a lower modulus in that direction. Strictly speaking, the term "graphite fibers" is a misnomer because there is no true graphite crystal structure in the fibers. The term "graphite fiber" is used to describe fibers that have a carbon content in excess of 99%, whereas the term "carbon fiber" describes fibers that have a carbon content of 80-95%. The carbon content is a function of the heat-treatment temperature. The current technology for producing carbon fibers generally centers on the thermal decomposition of various organic precursors. However, currently available carbon fibers are made using one of the three precursor materials: polyacrylonitrile (PAN), pitch, and rayon. Candidate organic materials for pyrolysis into carbon fibers having good properties should satisfy four criteria. First, the precursor should possess the appropriate strength and handling characteristics needed "to hold the fibers together" during all stages of the conversion process to carbon. Second, the precursor should not melt during any stage of the conversion process. This can be accomplished by either selecting infusible precursor material or by stabilizing a thermoplastic precursor prior to the conversion process. Third, the precursor material must not volatilize completely during the pyrolysis process: that is, the carbon yield of the precursor fiber after pyrolysis shouldbe appreciable enough to justify its use on an economic basis. Furthermore, in order to obtain optimal properties, the carbon atoms should tend to array themselves in an aligned graphite structure during pyrolysis. In general, the more highly graphitic and oriented the fibers, the better are the mechanical properties. Finally, the, precursor material should be as inexpensive as possible. One of the production methods for graphite fiber production is described below.

Graphite Fibers from PAN

The process by which PAN* is converted to carbon fibers involves five steps :
1. Spinning the PAN into a precursor fiber.
2. Stretching the precursor.
3. Stabilization by holding the prestretched polymer under tension at a. temperature of 205-240°C for uto 24 h in •an oxidizing atmosphere (air).
4. Carbonization at approximately 1500°C in an inert atmosphere. Carbonization is the process of pyrolizing stabilized PAN fibers to drive out most (if not all) noncarbon elements of the precursor fibers until they are essentially transformed into carbon1fibers. It is during this stage that the high mechanical properties found in most commercially available carbon fibers are developed.
5. Graphitization at approximately 3000°C in inert atmosphere. Graphitization heat treatments are carried out at temperatures in excess of 1800°C in order to improve the tensile modulus of elasticity of the fiber by improving the crystallite structure and preferred orientation of the graphitelike crystallite within each individual fiber.

Model nesting is the most commonly applied and traditional method of linking numerical and physical models. A global or regional numerical model provides the external boundary conditions for a smaller area, more detailed model. Model nesting is a common way to downscale numerical model results from the global to the local level or to drive a more detailed regional model from a less detailed, larger scale model. However, here we are interested in how to drive a physical model covering a small, specific area, from a numerical model of a wider area.

Carbon fibers produced from each precursor have distinct advantages and drawbacks in terms of both cost and properties. The PAN-based carbon fibers are lower in cost and have good properties. They are the dominant class of structural carbon fibers and are used widely in military aircraft, missiles, and spacecraft structures. Pitch-based carbon fibers generally have higher stiffness and thermal conductivities, which make them useful in satellite structures and thermal-management applications, such as space radiators and electronic enclosures. Rayon-based carbon fibers are not used for structural applications, but their low thermal conductivity makes them useful for insulating and ab~lative applications such as rocket nozzles, missile reentry vehicle nosecones, and heat shields. Typical property ranges of each class of carbon fibers. Carbon fibers are available in a great variety of property combinations because their properties can be altered easily by controlling their structure through manufacturing process (e.g., by heat-treatment temperature). Fiber properties change from batch to batch and also as manufacturers improveiber technology. The latest dat from the manufacturer should be consulte for specific fibers and their actual properties. Carbon fibers are available in various forms: continuous, chopped, wovel fabric, 01/ mat. Tows, yarn, rovings, and tape are the most common foons o conti'nuot4's-graphite fibers sold today. A tow consists of numerotrS rilament in a straight-laid bundle and is /specified by their number. Depending on th1 organic precursor and manufacturer, typical filament counts vary from 400- 10,000 or as high as 160,000. A ·yiim is a twisted tow, whereas a roving is : number of ends or strands collected in a parallel bundle with little or no twis and is specifiea by the number of ends. Finally, a tape consists of numerous tows or yarns' (e.g., 300) side by side on a backing or stitched together.

Various types of polymer fibers (e.g., nylon, polyester, rayon) have been i1 use for many years as reinforeements in automobile tires, large balloons am dirigibles, body armor, and rubber-coated fabrics.Polymer-aramid fibers (Kevlar) were first introduced in 1971. The aramil fiber-forming polymers, that is, the aromatic polyamides, are believed to b made by solution-polycondensation of diamines and diacid halides at lo, temperatures. The polymers are spun from strong acid solutions (e.g., concentrated H2S04) by a dry-jet wet spinning process. The polymers are madeby rapidly adding a diacid chloride to a cool (5-10°C) amine solution while stirring. The polymer thus formed is recovered from the crumbs or gel bypulverizing, washing, and drying. To form filaments, the clean polymer, mixed with strong acid, is extruded from spinne.rets at an elevated temperature (51-100°C) through a 0.5-1.9-cm layer of air into cold water (0-4°C). The fibers are then washed thoroughly in water and dried on bobbins. Fiber properties can be altered by using solvent additives, varying the spinning conditions, and using postspinning heat treatments. Kevlar fibers possess unique properties. Tensile strength and modulus are substantially higher and fiber elongation is significantly lower for Kevlar fibersthan for other organic fibers. Kevlar fibers have poor characteristics incompression, with compressive strength being only one-eighth the tensilestrength. This results from their anisotropic structure, which permits rather

easy local yielding, buckling, and kinking of the fiber in compression. They are not as brittle as glass or graphite fibers and can be readily woven on conventional fabric looms. Representative properties of Kevlar fibers.

Boron filaments are produced by chemical vapor deposftion (CVD) from the reduction of boron trichloride (BC13) with hydrogen on a tungsten or carbon monofilament substrate. The substrate is resistively heated to a temperature of 1260°C and pulled continuously through a reactor to obtain the desired boron coating thickness. Currently, boron filaments are produced with diameters of 100, 140, and 200 μm (4, 5.6, and 8 mils), in descending order ofproduction quantity; however, both smaller- and larger-diameter fibers havebeen produced in experimental quantities.The tensile strength of boron-tungsten filaments has improved steadilyover the past decade from an average of under 2750 MPa to over 3445 MPa.

The need for high-temperature reinforcing fibers has led to the development of ceramic fibers. The ceramic fibers combine high strength and elastic modulus with high-temperature capability and a general freedom from environmental attack. Alumina fibers and silicon carbide fibers are among the importan ceramic fibers. Alumina fibers marketed by Du Pont (E.I. Du Pont de Nemours & Co.) with the trade name "Fiber FP" are a continuous aalumina yarn with a 98% theoretical density. These fibers are made by spinning of an aqueous slurry and a two-step firing. As-produced Fiber FP surface is very rough. A thin silica coating enhances tensile strength by about 50%. An excellent feature of Fiber FP is its strength retention at high temperatures. They retain strength up to about 1370°C. Properties of Fiber FP . Silicon carbide (SiC) fibers are produced by a chemical vapor deposition (CVD) process (AVCO Specialty Materials Co.), as well as by controlled pyrolysis of a polymeric precursor (Nippon Carbon Co.-Nicalon fibers). Properties of SiC fibers . Silicon carbide fibers retain tensile strength well above 650°C. Alumina and SiC fibers are suitable for reinforcing meta matrices, in which carbon and boron fibers exhibit adverse reactivities. In addition, alumina has an inherent resistance to oxidation that is desirable in applications such as gas-turbine blades.

For different applicatiqns. The range of properties of the HPPE fibers, as reported by manufacturers. The reported properties often are influenced by the testing method, and actual usable properties of fibers may b~ lower than the reported values.

HPPE fibers have a density of only 0.97 g/cm3

Their modulus and strength are slightly lower than those of K5Ylar fibers but on a per-unit-weight basis, HPPE fibers have 30-40% higher strength and modulus than Kevlar fibers. High-energy absorption of HPPE fibers makes them suitable for use in ballistic protection applications. HPPE fiber-based composites perform exceptionally well against high~velocity impacts such as the ones produced by rifle rounds and shock waves from an explosion. This is so because the highvelocit impact produces a high strain-rate loading on the composite, and the strength and stiffness of the PE fibers increase at high strain rate. Highperformance body armors (concealed ballistic vests) made from these fibers provide comfort and maneuverability. They also find use in vehicles for se· curity and law enforcement blaSt-:dmtainment applications, and reinforce cockpit doors on commercial airliners. Major limitations in the application of HPPE fibers come from their lo"' melting point of I 50°C, an inert surface that makes it difficult to bond to othei polymers, and poor creep characteristics.

Fibers, because of their small cross-sectional dimensions, cannot be loaded directly. Further, fibers, acting alone, cannot transmit loads from one to an· other to be able to share a load. This severely limits their direct use in load· bearing engineering applications. This limitation is overcome by embeddini

Them in a matrix material to form a composite. The matrix binds the fiber: together, transfers loads between them, and protects them against environ· mental attack and damage due to handling. The matrix has a strong influenet on several mechanical properties of the composite, such as transverse modulw and strength, shear properties, and· properties ir1 compression. The matrb material frequently limits composite's service -femperature. Temperatunranges at which composites with different types of matriee can be use. Physical and chemical characteristics of the matrix, sudas· melting or curing temperatures, viscosity, and reactivity with fibers, influ. ence the choice of fabrication process. The matpx material for a compositesystem is selected keeping in view all these factors. Commonly used matrb materials are described in this section.

According to their structure and behavior, polymers can be classified as thermoplastics or thermosets. The polymers that soften or melt on heating, called thennoplastic polymers, consist of linear or branched-chain molecules having strong intramolecular bonds but weak intermolecular bonds. Melting and solidification of these polymers are reversible, and they can be reshaped by application of heat and pressure. They are either semicrystalline or amorphous in structure.

Examples include polyethylene, polystyrene, nylons, polycarbonate, polyacetals, polyamide-imide, polyether-ether ketone (PEEK), polysulfone, polyphenylene sulfide (PPS), and polyether imide. Thermosetting plastics have cross-linked or network structures with covalent bonds between all molecules. They do not melt but decompose on heating. Once solidified by a crosslinking (curing) process, they cannot be reshaped. Common examples of thermosetting polymers include epoxide~ polyesters, phenolics, ureas, melamine, silicone, and polyimides.

These transition temperatures are illustrated as measured by specific volume changes with temperature. Transition temperatures (Tg and Tm) of some polymers are given in Table 2-9. The temperature for processing of thermoplastics is governed by either the melt temperature or glass transition temperature. For example, an amorphous thermoplastic must be molded well above its Tg in order to reduce its melt viscosity sufficiently.

An understanding of the effect of these temperatures on the mechanical behavior of polymers is best seen by the behavior of modulus of elasticity (E) with temperature An amorphous thermoplastic (e.g., polystyrene, polycarbonate, or polymethylmethaerylate) has a significant change of mechanical properties at the glass transition temperature. Hence maximum use temperatures must be less than the glass transition temperatures. A thermoset (e.g .. epoxy, polyester, or phenolic) has a much reduced change in properties at the glass transition temperature because of its high degree of cross-linking. However, their maximum use temperatures should not exceed Tg. Semicrystalline thermoplastlics alsohave a modest change in properties at the glass transition temperature owing to the presence of the crystalline regions. Their maximum use temperatures are more dictated by the melting

These general shapes are applicable for crystalline or amorphous materials. It is important to recognize that these large variations in behavior can occurover a temperature range of only 100-200°C for some materials. Further, the rate of strain has a comparable effect, although much greater rate changes must occur to alter the behavior substantially. Thermosets also are not as affected by temperature and strain rate, the range of behavior being limited to approximately the higher three curves . Environmental influences (e.g., moisture absorption) also have a significant effect on the behavior of polymers, particularly relative to metals and ceramics For example, epoxy or polyester resins can absorb up to 4-5% by weight of water if exposed to 100% relative humidity or immersed in water. The mechanical properties of nylon thermoplastics are influenced significantly by their moisture contents. Polymers are also susceptible to deterioration as a result of exposure to ultraviolet radiation.

Polyester and epoxy resins are the most common polymeric matrix materials used with highperformance reinforcing fibers. Both are thermosetting polymers. Easy processibility and good chemical resistance are their chief advantages.

A polyester resin is an unsaturated (reactive) polyester solid dissolved in a polymerizable monomer. Unsaturated polyesters are long-chain linear polymers containing a number of carbon double bonds. They are made by a condensation reaction between a glycol (ethylene, propylene, or diethylene glycol) and an unsaturated dibasic acid (maleic or fumaric). A typical polyester resin made from reaction of maleic acid and diethylene glycol is shown below:

The length of the molecule or degree of polymerization n may vary. The resin generally will be a solid. It is dissolved in a polymerizable (reactive) monomer such as styrene, which also contains carbon double bonds and acts as a crosslinking agent by bridging adjacent polyester molecules at their unsaturation points. The monomer also acts as a diluent, reducing the viscosity of the polyester, and makes it easier to process. The curing or cross-linking process is initiated by adding a small quantity of a free-radical initiator/curing agent such as an organic peroxide (e.g., benzoyl peroxide) or an aliphatic azo compound. The styrene monomer cross-links or reacts with the double bond in the polyester backbone above to form a network polymer, as shown below:

Vinyl esters, polyimides, and phenolics are among the other thermosetting polymers that are used as matrix materials for composites. Vinyl esters are closely related to the unsaturated polyesters. Like unsaturated polyesters, they possess low viscosity and cure fast but are slightly more expensive. They possess exceptional mechanical and chemical performance characteristics and thus provide a transition in mechanical properties and cost between polyesters and the high-performance epoxy resins. Vinyl esters often are used because of their ease and speed of processing and their good resistance to wet environments. Their applications include high performance gel coats, pipes, and reaction vessels.
Polyimides have a relatively high service temperature range (250-300"C). They also possess excellent chemical and solvent resistance. Bismaleimide (BMIs) are the most widely used thermosetting polyimides for composites employed at high temperatures. However, these materials are inherently very brittle, and thus they are often combined with polysulfone, polyetherimide, or other thermoplastics. The handling and processing techniques for BMI resins are similar to those for epoxy resins. Their applications include aerospace wing-skin ribs, helicopter firewalls, and printed wiring boards. Phenolic resins have low flammability, low smoke production, good dimensional stability under temperature fluctuations, and good adhesive properties. Phenolics are attractive for aircraft and mass-transit vehicles and as interior construction materials where outgassing due to fire must be extremelylow.

Phenolics also are used for rocket nozzle ablative and insulation liners. Chopped-fiber molding compounds of phenolic resin are used mostly in the automotive, appliance, and electrical component markets.

Fillers Fillers are used widely in polymeric composites primarily to reduce cost with some sacrifice in physical properties. They also are used to reduce shrinkage, control viscosity, and improve part stiffness. Commonly used fillers include calcium carbonate, kaolin (china clay), silica (sand), feldspar,talc, and glass microspheres. Fillers are not as common in highperformance composites because they may adversely affect the fiber-resinload transfer and decrease the toughness of the resin at high filler content.Calcium carbonate (CaC03) is a widely used filler for both economic and performance considerations.Glass-fiber-reinforced polyesters from sheetmolding compounds or bulk-molding compounds may contain substantial amounts of CaC03 for cost reduction and shrinkage control. High surface smoothness may be achieved and sink marks eliminated. Kaolin is used to increase resin viscosity to prevent fibers from extruding from molded surfaces. It also improves the fire resistance of the compound.Natural silicas are used in thermoset resins for dimensional stability, good electrical insulation, and improved thermal conductivity. Talc (hydrated magnesium silicate), in the form of finely ground thin platelets,

Is added to resins to improve stiffness and creep resistance. Some natural organic materials such as wood flour, shell fibers (e.g., shell of almond, coconut, peanut, walnut, etc.), and cotton and vegetable fibers (e.g., hemp, jute, ramie, and sisal) are also used as fillers. Hollow microspheres made from glass or polymers can be used to reduce thedensity of the resin significantly. Additives used for fire resistance (e.g., antimony oxide), chemical thickening (e.g, magnesium oxide and calcium hydroxide), and for lowering shrinkage (e.g ., fine-powdered polyethylene) are also common. For more detailed information on fillers and additives, the reader shouldrefer to the books suggested at the end of this chapter.

Metals are by far the most versatile engineering materials. The properties that are particularly important for their use as matrix materials in composites include high strength, high modulus, high toughness and impact resistance, and relative insensitivity to temperature changes.

1.3 Summary

Here the introductory part about the analysis and effect of shim used in a composite and metal bolted joints.

CHAPTER 2

LITERATURE REVIEW

The report explains his works that consists on a new experimental methodology for testing metal-composite bolted joints. Single-lap titanium-composite structure joints attached by monel fasteners were investigated. Finite element analysis was carried out in order to predict the mechanical behaviour of the joints up to the first failure, as well as to aid test setup. The experimental tests were carried out by using geometry specifications for composite-composite joints, and procedures established by the Secondary-Modulus Method for metal-metal joints. Based on the experimental tests, using the proposed methodology it was possible to observe the mechanical behaviour of the metal-composite joints, mainly to determine the stiffness and strength of the structures. Therefore, the proposed methodology can contribute for designing metal-composite bolted joints, estimating not only the compliance but also allowable stress values for those structures .

This thesis deals with composite joints with single shear tensile loading for a single piece specimen. The bearing response data from single shear test using a single piece specimen has been extensively used in the development of design allowable data. The first objective of the work was to test three different displacement gauge position configurations for determining the bearing chord modulus and the 2% offset strength of composite coupons. Testing was done according to ASTM D5961: Procedure 'C' - the standard test procedure for the bearing response of a single shear one-piece polymer matrix composite laminate. The Procedure 'C' testing method is not yet standardized by the ASTM and there is a great deal of confusion in the extensometer position. Hence, an attempt has been made to study the variability in the chord modulus, and more importantly the 2% offset bearing strength depending on the different reference positions of the displacement gage placement. The other aim of thesis was to build a finite element (FE) model for a quasi-isotropic material, to justify the FE results with experimental results, and then to conduct a set of parametric studies to study the stiffness behaviour in all the three positions. The statistical analysis using Design of Experiments (DOE) of the parametric study data, identified significant factors affecting the results .

In this study, analytical models with different material and geometry for both single and double- lap bolted joints were reviewed for better understanding on how to select the proper model for a particular application. The survey indicates that the analytic models selected for the adhesively

single or double bolted lap joints, as well as T, scarf, and stepped joints, with linear material properties are mostly two dimensional and the studies on stress distribution and/or failure of the joints are performed experimentally, analytically or by finite element method. The results seem to be generally accurate and adequate. Additionally, it was shown that any increase in the bolt-hole clearance leads to an increase in bolt rotation, as well as a decrease in bolt-hole contact area. Hence, there is a reduction in joint stiffness. Moreover, studies on hybrid joints have revealed that the proper choice of adhesive material in conjunction with bolts or rivets in a joint, allows for significant increase in the static and fatigue strength compared to similar pure bonded joints. Additionally, the results on hybrid scarf joints showed that it is vital to place fasteners closer to the ends of the overlap to suppress the peak peeling stresses and hence, delay the effects of early crack initiation in the adhesive layer. Experimental studies on fatigue behaviour and strength of bolted joints have shown that compared to clearance fit specimens, clamping force increases the fatigue life of a bolted joint. Moreover, higher tightening torque, in general, results in higher fatigue lives in bolted joints .

The formation of micro-cracks and crack propagation is still an acute problem in polymer and polymer composites. These micro-cracks usually occur while the materials are manufactured or serviced. The development and coalescence of these cracks reduces the lifespan and brings about a catastrophic failure of the materials. Novel scientific research on polymeric self-healing is emphasised in a number of publications, which consist of contributions from many of the prominent researchers in this area. Progress in this field can eventually enable scientist to construct new flexible materials that both monitor the material's integrity and repair the deformed material prior to the occurrence of any fatal failures. This report describes recent trends that have been used in material science and computational methods to mitigate the development of micro-cracks and crack propagation in polymer composites.

Prepregs are fibre-reinforced resins that cure under heat and pressure to form exceptionally strong yet lightweight components. Hexcel is a world leader in prepreg technology and this guide has been written to provide a greater understanding of prepregs, how they are manufactured, processed their properties and varied applications. Information is provided to guide you through the choice of the most suitable prepreg and processing method for an application. To assist with product selection Hexcel has produced PREPREG MATRIX SELECTOR GUIDES for Aerospace and Industrial applications which are available on request. For more information on our product range, prepreg selection or processing techniques please contact Hexcel .

2.1 Summary

Based on the above research is considered as a foundation for our project for composite and bolted joints.

CHAPTER 3

MODELLING

The specimen is modelled using CATIA V5. Initially the parts such as top and bottom plate, shim, nut and bolt are designed using part design feature. Then these parts are assembled to model the specimen using assembly design feature. Fig.3. 1 shows the CAD models of the different parts and also the assembled model.

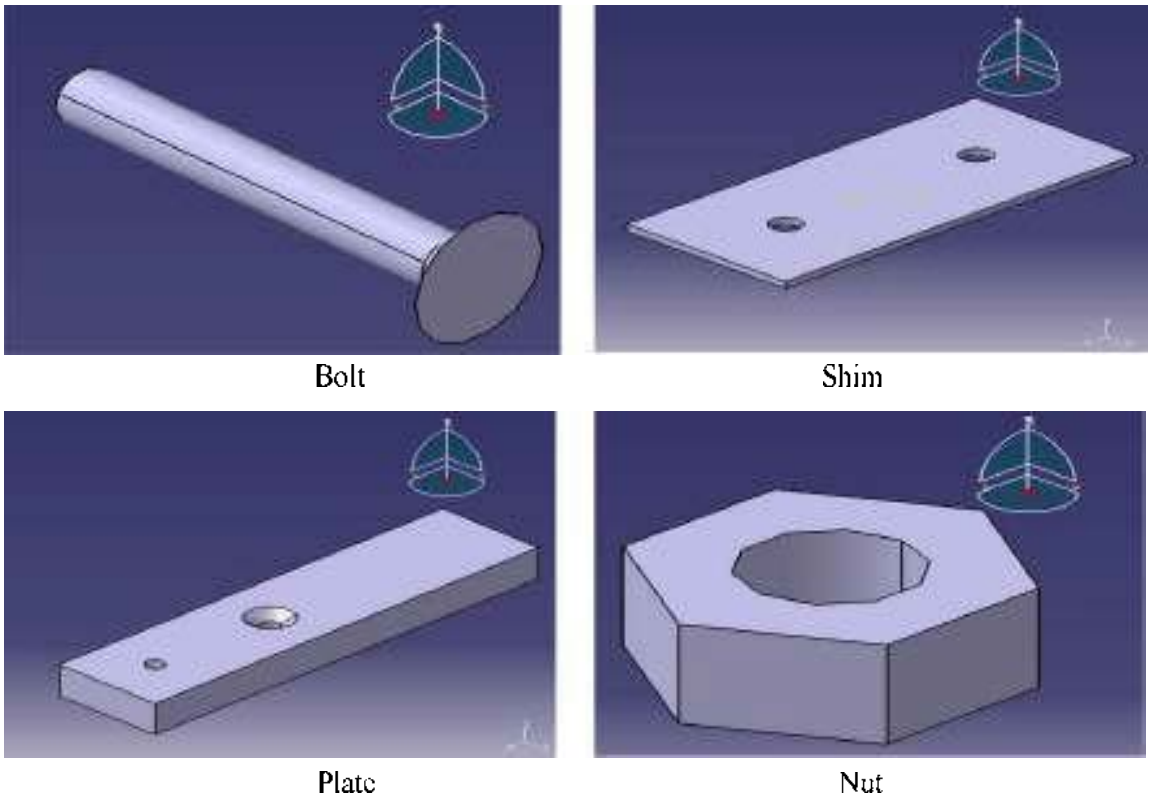

Fig 3.1 : Modelling of bolt, nut, shim and plate

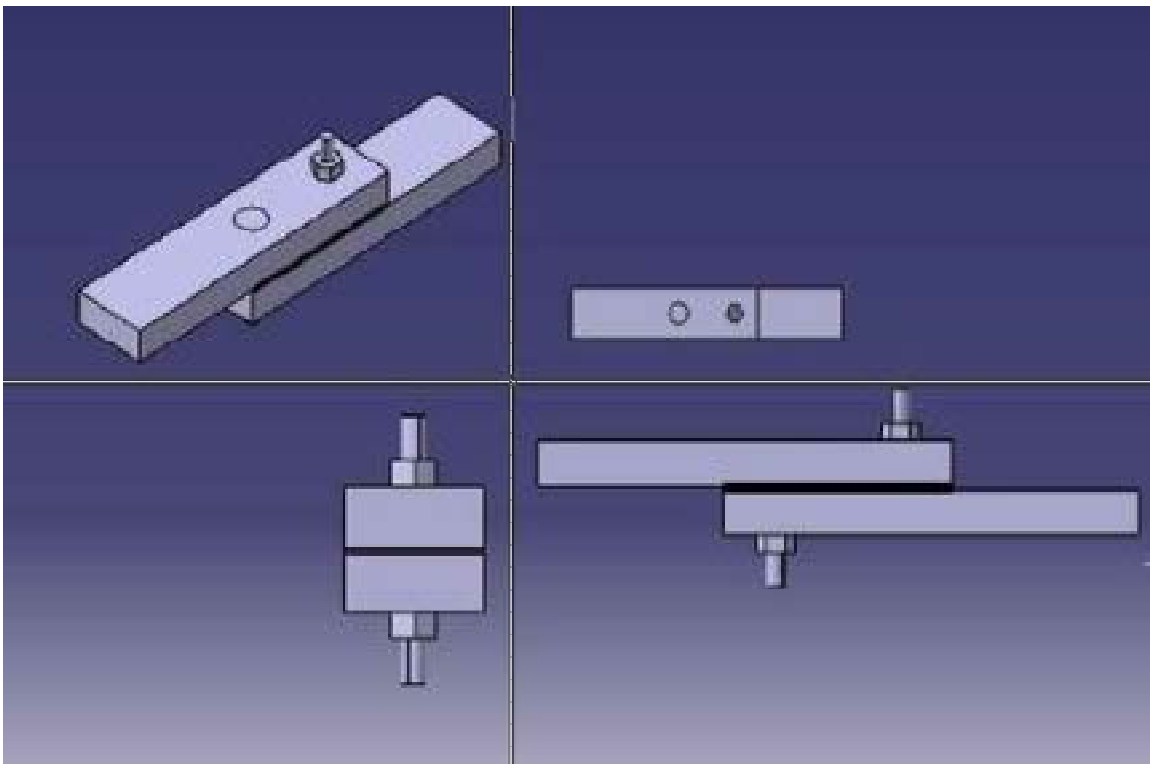

Fig. 3.2 : CAD models of the specimen

An unusual extension of this composite modeling approach involved the physical and numerical models covering the same domains (van den Boogaard et al, 2009, summarized in Gerritsen et al, 2009, Gerritsen and Sutherland, 2011). Here wave propagation over a nearshore bar was modeled using a physical and a numerical model to determine the worst cases wave conditions at the toe of a seawall. The worst case was determined by the geometry of the nearshore bar and intertidal terrace, so several geometries had to be modeled for each wave condition. In general terms, physical wave experiments for near-shore problems are accurate but expensive and time consuming, while numerical wave modelling for these problems is flexible, relatively fast and cheap, but still much less accurate. An error correction technique was devised to use the results of the physical model to correct the results of the numerical model. The error correction procedure was based on an artificial neural network model of type Multilayer Perceptron. A priori knowledge and analysis were used to reduce the dimensionality of the problem to acceptable limits.

In this way the speed and flexibility of the numerical model was combined with the accuracy of the physical model so that the worst case of nearshore bathymetry could be determined. Moreover, the above combination of both models significantly reduced the number of flume experiments needed to derive the most critical bed geometry for the defined problem.

While individual length-scale and time-scale computational approaches provide extremely useful information, there is a need for an integrated multi-scale simulation approach to investigate existing and novel composite materials. Based on the current research efforts, we are hoping to see the development of multi-scale simulation approaches to examine composites in the near future.

One example of this involves the design of lock filling and emptying (F/E) systems. A numerical model with 1D pressure flow and 1D open channel flow was used to model the F/E system. The head loss of each component must be represented in such a system, but this is difficult to estimate for a complex culvert. Therefore the numerical model was used to model the system with standard textbook head losses. A physical model of a culvert was constructed and run. Pressure gradients were measured and flow patterns were observed (as an even flow distribution is desired). The culvert design was optimized based on the physical model results. The head losses derived from measurements on the physical model were then incorporated into the numerical model so that the overall design could be optimized (Bousmar, 2010, personal communication).

Both of these examples are similar to the composite modeling approach advocated by Oumeraci (1999) for whom the principle of Composite Modelling consists in subdividing a very complex and complicated problem into several simple and more easily tractable processes which can be described by the most appropriate methods in order to get the most reliable process models, including physical and validated numerical and analytical models. These models should then be combined using a hydro-informatics approach. As the hydro-informatics approach taken commonly consists of the development of a numerical model including behavioral (parameterized) elements, this can be seen as a typical means of numerical model development. However, in these cases the physical model tests were designed to produce sit-specific and conditions-specific results, which were not intended to be generalized for use in a numerical model of other similar cases.

In a coastal area where a breakwater is being built, for example, it may be necessary to construct a physical model to test armour stability, scour, overtopping or any other nonlinear phenomenon that cannot accurately be represented in a numerical model. In this case an offshore wave condition would typically be obtained and a regional wave model used to propagate the desired wave conditions inshore, modelling processes such as shoaling, refraction and possibly diffraction. The modelled wave condition is output at typically one location in relatively deep water at the offshore edge of the physical model. A characteristic wave height and wave period (often the significant wave height and peak wave period) is extracted from the numerical model, even if it is a spectral model with wave-wave interactions that contains much more information than simply height and period. A wavemaker will then generate an irregular but normally longcrested sea state with a standard spectral shape.

3.1 Summary

The above modelling is designed in CATIA V5 software. And it's designed in upper and lower plate, nut, bold and shim.

CHAPTER 4

MESHING

Meshing is done using NFX. The plates, bolts and the shim are meshed separately to maintain the quality of mesh. Fig. 4.1 shows the mesh files of the individual parts.

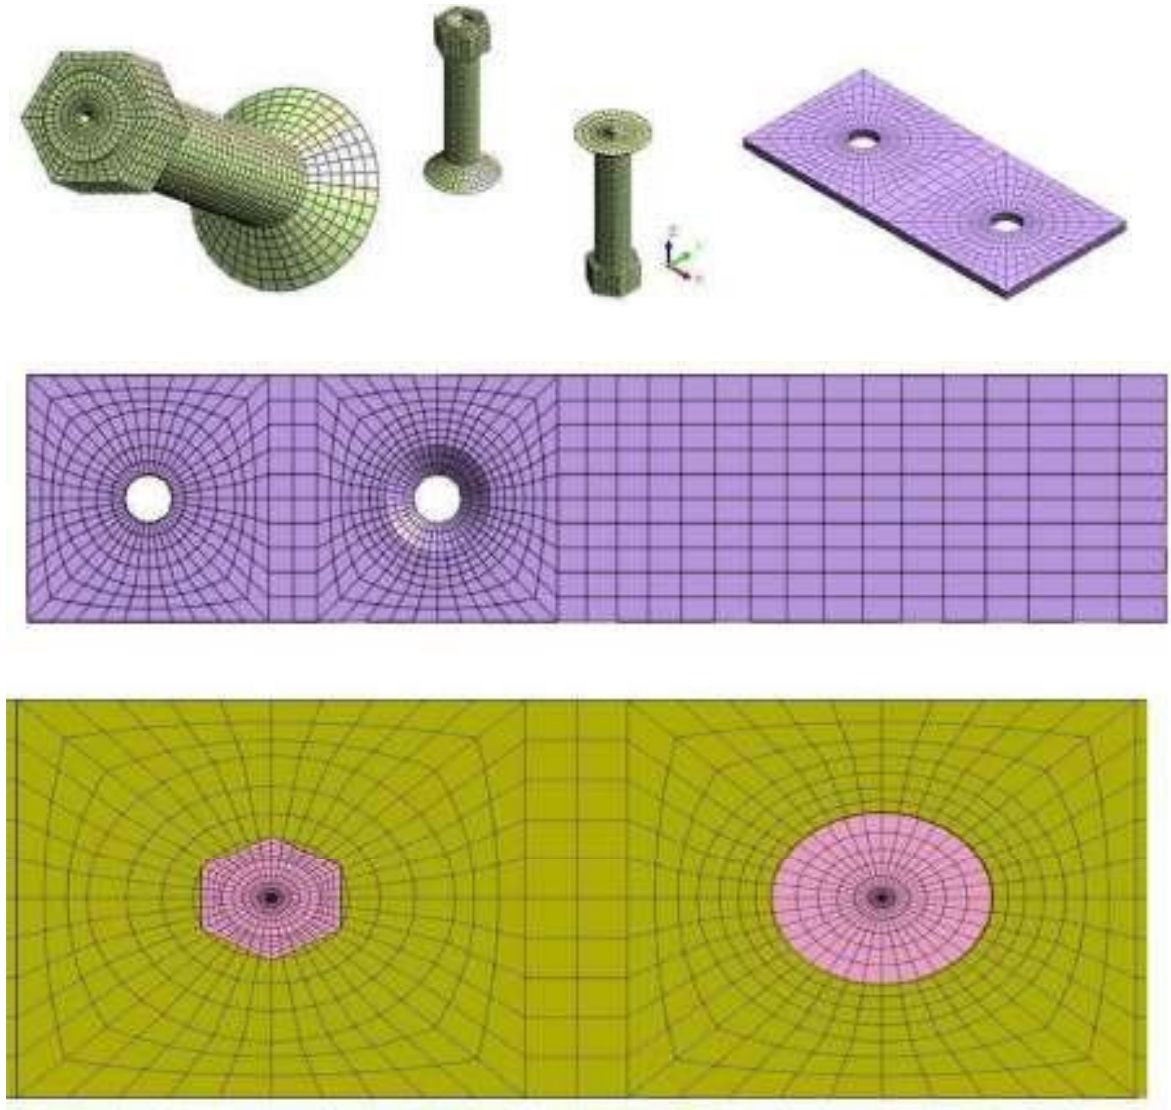

Fig. 4.1: Mesh of individual parts

4.1 Finite Element Analysis:

The tensile test is carried out in MIDAS NFX 2019. The right end of the top plate is made as a rigid body to apply load. The entire model is constrained in Y and Z direction to prevent movement in y and z directions. The left end of the bottom plate is fixed and the load is applied on the rigid body on the right end of the top plate. Fig. 4.2 shows the specimen with boundary condition and applied load. FEA is done for specimens with three different thickness and with varying the dimensions of the shim. Displacement and von Mises stress distribution is obtained for all specimens.

Fig. 4.2: Specimen with constraints and applied load

4.2 Summary

The meshing and finite element analysis run in MIDAS NFX software. To distribute the weight in each and every parts in the upper and lower plate

CHAPTER 5

MATERIALS AND PROPERTIES

The top and bottom plates are made with hexcel prepreg made with carbon IM7 as fibre and epoxy 8552 as resin. The bolt is considered as titanium and the shim is made up of epoxy resin. The stacking sequence of 3 different specimens are $[45/-45/90/0/45/-45/90/0/45/-45/90/0]_s$, $[45/-45/90/0/45/-45/90/0/45/-45/90/0/45/-45/90/0]_s$ and $[45/-45/90/0/45/-45/90/0/45/-45/90/0/45/-45/90/0/45/-45/90/0/45/-45/90/0]_s$ respectively. The shim thickness is varied from 0 mm to 2 mm with an interval of 0.5 mm. Here the composite laminate is assumed as 3D anisotropic material whereas the shim and bolts are assumed as 3D isotropic materials. The material properties for the prepreg is given in Table 1. Also the material properties of titanium and epoxy resin is given in Table 5.1

5.2. Properties of epoxy and titanium

Material	E (MPa)	V
Titanium	110000	0.3
Epoxy	6000	0.35

5.1 Contact Pairs:

Contact pairs are created in MIDAS NFX to create contact between the individual parts. Three contact pairs are created (between plates and bolt head, between plate and shim and between plates and bolt middle portion). Welded contact is provided for plates and bolts whereas sliding contact is provided between plates and shim. Fig. 3 shows the master and slave of the contact pairs.

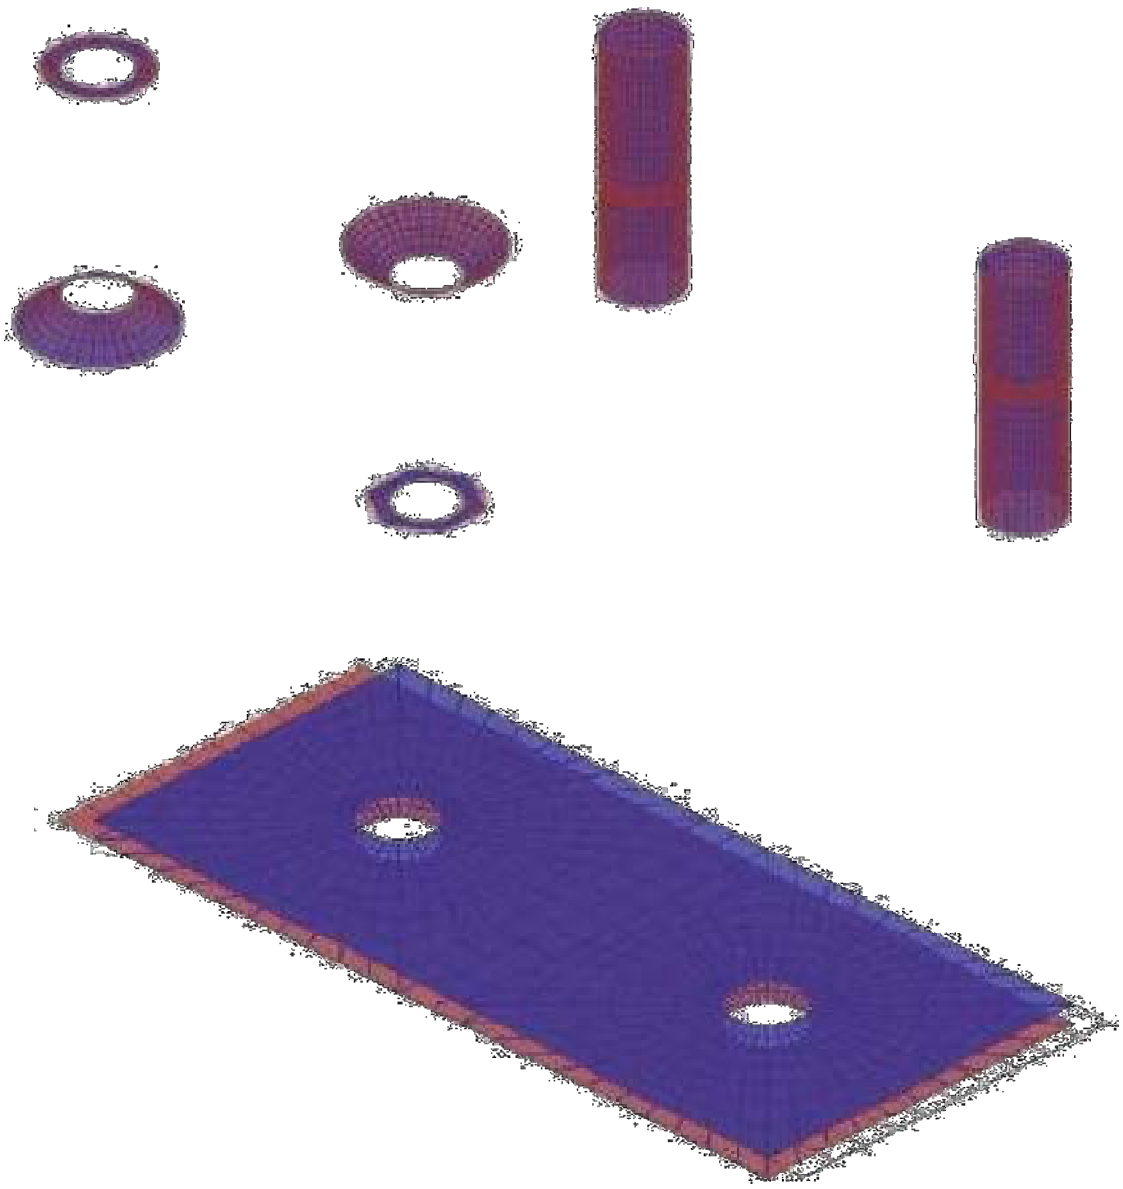

Fig. 5.1: Contact Pairs

5.2 Summary

The above materials and properties are choosing based upon the quality and strong materials. Contact pairs meshed in MIDAX NFX Software in individual parts of nut and bolt heads and plate and bolt mid span.

CHAPTER 6

CALCULATIONS

The top and bottom plate is made with three different kinds of thickness such as 12.7, 8.48 and 6.36 mm respectively. The diameter of the bolt is fixed as 6.35 mm. The bearing allowable stress is considered as 758 MPa. The applied load for tensile test is obtained using the bearing allowable stress. is used to calculate the applied load.

For t=12.7 mm and d=6.35 mm, P=758*12.7*6.35 =61129 N

For t= 8.48 mm and d= 6.35mm, P= 758*8.48*6.35 = 40817 N

For t= 6.36 mm and d= 6.35mm, P= 758*6.36*6.35 = 30613 N

Table 6.1 shows the thickness of top and bottom plates, thickness of shim, total thickness of the specimen and diameter of the bolt. Table 4 shows the applied load calculated for three different specimen thickness.

Table: 6.1 Specimen dimensions

Specimen ID	t_u (mm)	t_l (mm)	t_s (mm)	t_{total} (mm)	d (mm)

Different graphs were plotted to understand the displacement and stress variations with respect to shim to total thickness ratio as shown in Fig. 7.5 and fig 7.6

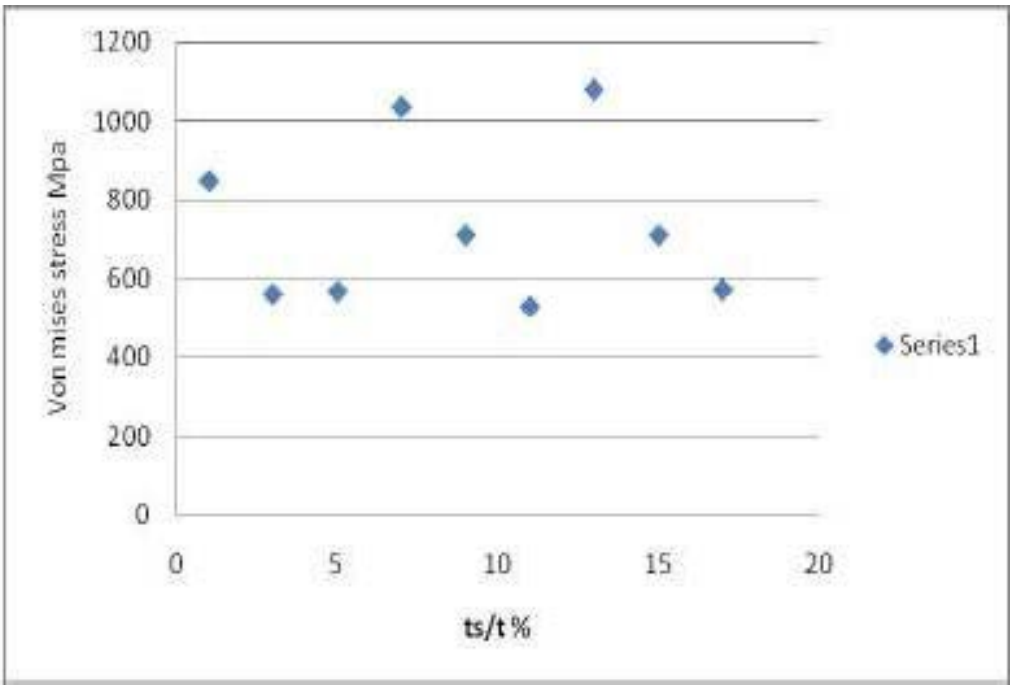

Fig. 7.5: von Mises stress vs. t_s/t_{total} (%) of bolt

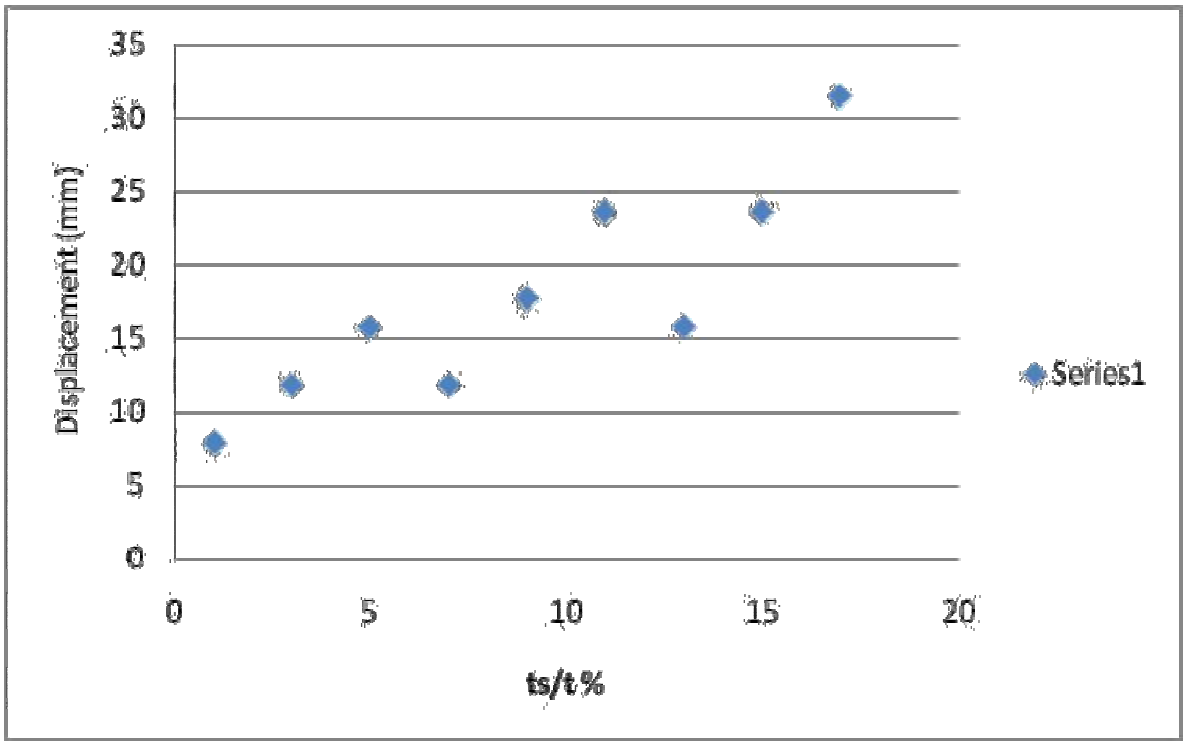

Fig. 7.6: Displacement vs. t_s/t_{total} (%) of specimen

7.1 Summary

The result is compared to the with shim and without shim in five different shim thicknesses. The shim thickness in 2 mm is sustained more stress in other shim thicknesses.

CHAPTER 8

CONCLUSIONS

Finite element simulations play a vital role in the design validation of concepts at the early stages of any validation of engineering substance. In this work, the design and analysis of an effect in shims in a composite and metal bolted joint has been validated through the use of finite element simulations in which the simulation depicted the true deformation iterations and the stress levels observed for various shimmy joints will be coincided with the engineering judgement. The following conclusions are observed after the tensile test of specimens with varying thickness of top and bottom plates and shim of varying thickness. From the graphs we came to know that more stress is obtained in bolts than the plates. Also it clearly showed that the stress increases with the shim thickness but it decreases when we reduce the thickness of the thickness of the top and bottom plates. After observing the displacement plots, we came to know that the displacement increases when there is an increase in the shim thickness and also it decreases when we reduce the thickness.

ABSTRACT; This paper study the behaviour of joints, that most of the composites can't be riveted. Mostly bonding (adhesives) technique is used to join the two different materials, like metal to composites and composites-composites. Our work is to address the behaviour (strength and life time) of different composite and metal joints using FEA analysis. Which will reduce the time and cost of the testing. There are different techniques (from literature) which have been considered and by using different thickness layer of shim with bolted joints in the composite material and compare the results with the test results.

1. INTRODUCTION

Composite materials are being extensively used in an aircraft manufacturing industries. The property of weight saving is the main driving force which benefits fatigue and corrosion resistance properties. A clear trend in composites is being increasing with in heavily loaded primary structures. The increasing use of Composite materials and its popularity has prompted significant changes in the field of research and developing for reliable design methods. Designing useful structures that means several parts must be joined together. This can be done only by adhesive, mechanical or hybrid joins which is mainly combination of the first two techniques. With low weight and good sealing properties the adhesive joints have advantage over the mechanical joints. Also mean while the adhesive joints are sensitive to environmental conditions and adhesive structures cannot be easily replaced while some parts get damage. Mechanical joining, i.e. using fasteners, is the most common method in an aerospace industry.

EFFECTS OF ORGANIC LIQUID FERTILIZERS ON SOIL PROPERTIES AND GROWTH OF BRINJAL

ABSTRACT

Nowadays, the synthetic fertilizers are used in agriculture when compared with organic fertilizer. But the continuous use of chemical fertilizers are diminishing soil fertility, health threads to human, livestock and also microbial community present in the soil. Applying liquid fertilizers directly to the root zone will provide an immediate effect on plant growth because the solution of fertilizer acts quickly to make the nutrients available to plants. The treatment of liquid fertilizer is prepared from waste materials. The different liquid organic fertilizers are Banana peel, Cow dung, Coconut cake, Groundnut cake and Vegetable waste.

The main intention of this project to compare the performance of different organic liquid fertilizers and to find out the nutrients present in the soil. With the help of parameters like pH, electrical conductivity (EC), nutrients of soil like nitrogen, phosphorous, potassium, organic carbon and plant growth.

KEY WORDS:

Organic liquid fertilizer, pH, Electrical conductivity, nutrients.

CHAPTER 1

INTRODUCTION

1.1. GENERAL

Organic liquid fertilizer is natural or artificial substance containing all macro and micro essential nutrients that improve the growth and productiveness of plants, enhance the natural fertility of the soil or replace the chemical elements taken from the soil by previous crops or other factors and improve the essential micro-organisms in the soil. Liquid concentrates are rich in nitrogen and defined as fertilizers containing organic elements including sulphur and trace metal elements used in agricultural applications. Liquid concentrate provides features such as organic form of nitrogen and adds positive value, compared to typical industrial fertilizers. The fertilizer, available to be used for plants are produced from completely natural raw materials without causing damage to the environment. After making necessary specifications these fertilizers can be sold through the agency of retail or fertilizer producers. Fertilizers are simply plant nutrients applied to agricultural fields to supplement required elements found naturally in the soil.

Liquid organic fertilizers consist of essential plant nutrients and beneficial microorganisms, which recycle organic matter. Microorganisms have an important role on the degradation of substrates in the fermentation process. However, it is a rich source of nutrients (nitrogen, phosphorus and potassium). Liquid organic fertilizers are generally having low concentration of chemical compounds with fairly good nutrient content to fulfil the plant requirement. If there is an excessive amount of the fertilizer in the soil, the plants can easily control its absorption. Liquid fertilizers are concentrated liquids that are added to water and applied to the soil and foliage. These types of fertilizers contain a synthetic chemical mix of the plant's essential nutrients, including nitrogen, phosphorus, potassium and iron. Organic liquid fertilizers are generally better for edible plants that produce fruit and veggies, because they are made from purely organic materials, whilst still releasing the nutrients they need. The great thing about liquid fertilizers is that they feed your plants the nutrients they need quickly, as well as adding beneficial bacteria, fungi and organic matter that improves your soil or potting mix. Organic fertilizer inputs in agricultural fields in the present scenario has significant environmental benefits over the use of chemical fertilizers and the practice has gained much importance. One of the advantages of using liquid organic

fertilizers into plants is the easily absorbed nutrients in the fertilizers by the soil that can readily be utilized by the plants.

The application of organic liquid fertilizers is using foliage, fertigation and direct spray to the soil. The fertigation organic liquid fertilizer especially, Nitrogen and phosphorus are the two primary nutrients injected through fertigation systems. Liquid fertilizer can offer opportunities for more efficient nitrogen use when they are applied through a drip irrigation system such an application is called fertigation. Any nutrient in a water - soluble form is readily available for plant uptake just after application, leading to a more efficient use of fertilizers. When nutrients are applied shortly before they are needed, growers can reduce loss of nutrients from the root zone. These liquid fertilizers may be applied on a regular basis, depending on the nutrient need of the crop. This allows the growers greater control over nutrient availability to their crop. Fertigation can provide supplemental doses of these nutrients, especially at critical periods during the growing season such as vegetative growth, flowering and fruit filling or blooming. The organic liquid fertilizers used for fertigation such as N, P, K and micro-nutrients to increase vegetable production per area or plant through improving soil fertility. Their ease of handling, low labour requirement, and the possibility of mixing with herbicides have made liquid fertilizers more acceptable to farmers. And the farmers were interested on the soluble organic fertilizers using drip irrigation.

1.2 BENEFITS OF USING ORGANIC LIQUID FERTILIZER

Liquid fertilizers offer a quick response and are applied to plants and lawn using spray bottles or sprinkler attachments. Because they are absorbed through the water directly into the roots of the plants, liquid fertilizers provide an immediate effect.

FAST ACTING:

The plant's root systems absorb most of the nutrients and provide a rapid green-up of your garden at a lower cost A small amount of these nutrients are taken through the leaves as well. One of the benefits of liquid fertilizers that because the liquid penetrates the soil immediately, plants are given faster access to the nutrients. Some plants will see results from this application almost immediately.

EASIER TO HANDLE:

No clean up, easily mixed into your daily watering and offers a uniform application. It is an easy process to apply the liquid fertilizer, and it is worked into the soil in more uniform ways.

UNIFORM APPLICATION:

When granular fertilizers are applied, they can be dropped in patterns throughout fields that are not necessarily uniform, which simply is a matter of it being a solid rather than a liquid. Liquid fertilizers can seep into the soil and spread more uniformly, thus giving your fields an even consistent coating so that all plants receive the same nutrients regardless of location.

COMBINED FERTILIZER AND PESTICIDES:

To apply on one pass over the lawn and garden, saving time and money. This better coverage also helps to combat weeds too.

1.3 OBJECTIVES

- ✓ To improve soil fertility.
- ✓ To prevent the soil from chemical pollution and toxic residues.
- ✓ To reduce salinity.
- ✓ To restore the ecological balance.

CHAPTER 2

REVIEW OF LITERATURE

Abhishek Raj, Manoj Kumar Jhariya, Pratap Toppo (2019) entitled as **"COW DUNG FOR ECOFRIENDLY AND SUSTAINABLE PRODUCTIVE FARMING"** said Cow dung is a most important source of bio-fertilizer. It is very effective's alternatives to chemical fertilizers by enhancing productivity in long term with maintaining the soil health and enhances the microbial population. Cow dung manure and vermicompost increases soil organic matter content, and this leads to improved water infiltration and water holding capacity as well as an increased cation exchange capacity. As per Fulhage (2000) manure contains the three major plant nutrients, nitrogen, phosphorus and potassium (NPK), as well as many essential nutrients such as Ca, Mg, S, Zn, B, Cu, Mn etc. That, in addition to supplying plant nutrients, manure generally improves soil tilth, aeration, and water holding capacity of the soil and promotes growth of beneficial soil organisms.in addition to supplying plant nutrients, manure generally improves soil tilth, aeration and promotes growth of beneficial soil organisms. Cow dung and cow's urine products, which can be used as fertilizers and pest repellent in agricultural practice. It showed positive response in suppress the growth of plant pathogenic fungi like *Fusarium solani, F. oxysporum.* Similarly, as per Mary *et al.* (1986) cow dung extract spray was also reported to be effective for the control of bacterial blight disease of rice and was as effective as penicillin, paushamycin and streptomycin. As per Pammel (1889) cow dung as organic manure increase vigour of plant and reduce the disease incidence of root rots in cotton caused by *Phymatotrichum omnivorum*.

From this literature, we conclude that the Application of cow dung in a sustainable way can enhance not only productivity of yield but also minimizing the chances of bacterial and fungal pathogenic disease. Due to increasing prices of chemical fertilizer and non-efficient role in long term to sustainable production, there is a need of application of organic manure including cow dung for enhancing maximum productivity in sustainable way with better soil health. It is an effective tool to improves physio - chemical and biological properties of the soil with higher yield of plants in sustained basis without deleting the fertility of soil. It can be also productively used for basic energy, biogas, electricity and fertilizer and has a strong socioeconomic dimension. The effective use of dung would contribute to increase energy security and reduce environmental degradation and greenhouse

S. Ginandjar, B. Frasetya, W. Nugraha and M. Subandi (2019) entitled as **"THE EFFECT OF LIQUID ORGANIC FERTILIZER OF VEGETABLE WASTE AND PLANTING MEDIA ON GROWTH AND YIELD OF STRAWBERRY"** said Increasing growth and yield of strawberry plant can be achieved by applying liquid organic fertilizer (LOF) of vegetable waste and planting media. This research was conducted to study interaction between Liquid organic fertilizer and planting medium and to inquire about the best dosage of Liquid organic fertilizer and planting medium for the growth and yield of strawberry. The first factor was vegetable waste of LOF with four treatments level respectively: p0: without LOF application, p1:250 ml, p2: 500 ml, and p3: 750 ml. The second factor was planting media with three treatments level respectively: m0: without husk charcoal, m1: (1:1) soil and husk charcoal, m2: (1:2) soil and husk charcoal. LOF vegetable waste preparation of liquid organic fertilizer for vegetable waste is done for 2 weeks according to the method of making LOF for vegetable waste. The application of liquid organic fertilizer is very good against the growth of plant height in each observation is indicated by there is a significant influence on the dosing of 500 ml and 750 ml. The highest rate of plant growth was demonstrated at 60 DAP at treatment of p3 with dose of 750 ml with a very significant effect on this matter. Liquid organic fertilizer waste can increase the availability of nutrients Ca, Mg and K surrounding soil and the presence of growth regulators such as auxin, spur leaf formation. Application of liquid organic fertilizer, vegetable waste done on 7 days before planting on planting medium and 21 DAP. The amount of leaf and plant height depends on the availability of nutrients absorbed. Liquid organic fertilizer of vegetable waste plays a role in the provision of nutrients and nutrients for plants.

From this literature, we know that the Organic fertilizers can provide ingredients of amino acids, proteins and contain substances that grow the auxin that plays a role in spurring root growth and ready to build a network of plant growth. Increased root growth and the formation of tissues on and leaves in large and large quantities can support the increase in fresh weight of plants. The advantages of liquid organic fertilizer are to provide nutrients in accordance with the needs of plants. Organic material is now promoted by farmers to support the application of organic farming. The number of microorganism population at soil used as an indicator for soil degradation. The natural pesticide was proven to be better and more profitable, biological control of pest will avoid ecology contamination with chemical pesticides, and be compatible with other methods of pest control.

Papa Malick Sall, Hani Antoun, Francois-P. Chalifour & Chantal J. Beauchamp (2019) entitled as **"POTENTIAL USE OF LEACHATE FROM COMPOSTED FRUIT AND VEGETABLE WASTE AS FERTILIZER FOR CORN"** said Composting fruit and vegetable waste from grocery stores on farms is a challenge due to the large quantity of liquid that leaches out. This leachate needs to be characterized for its effects on plant growth and soil. It was acidic with high conductivity, the plant mineral nutrient contents derived from the leachate (in decreasing order) were K, N mainly as ammonium-N, Ca, Mg, Na, and P; the trace elements were quite low. These results demonstrate the opportunity of recycling plant nutrients from compost leachate of fruit and vegetable waste as composting 6000 kg of fruit and vegetable waste generated about 400 L of leachate per day. After harvesting, soil samples were taken at depths of 0–20 and 20–40 cm, air-dried, and sieved at 2 mm before pH (1:1 soil:water (w:v)) and electrical conductivity (1:5 soil:water (w:v)) determinations. For total N, soil samples were ground at 100 mesh and analyzed as previously described. The leachate obtained was brown with an unpleasant odor that could be attributed to the organic acids and volatile fatty acids produced from composting food waste. Therefore, the physicochemical composition and effects of the leachate produced by fruit and vegetable waste compost were investigated. First, the plant mineral nutrients, including the trace elements, were determined. Then, under controlled environmental conditions, the phytotoxicity of leachate for cress and corn germination, and corn grown in pots were studied. Finally, the effects of leachate on corn yield and soil accumulation of plant nutrients were investigated in small field plots. At the end of the growing season, soil samples at depths of 0–20 and 20–40 cm were analyzed.

From this literature, we know that the germination and rootlet growth of cress and corn increased with the dilution of the compost leachate. In a field study on sandy loam, corn yields and plant uptake of P and K were similar among the mineral fertilized control and split application leachate treatments applied to meet the P or K requirements of corn. After harvest, the soil pH, conductivity, and total N, P, and K contents were not affected by the leachate treatments. No significant differences among the treatments and controls were measured in terms of soil pH, electrical conductivity, total N, and available P and K. In this study, the sandy loam and rainy weather could have prevented K accumulation in the soil. Lastly, the acidic property of the compost leachate could have prevented the buildup of soil K. Within these limits, the leachate-fertilized treatment could be used to substitute most mineral fertilizers for corn .

Lalnunpuia, Arun Alfred David, Syed H Mahzar, Tarence Thomas and Smriti Rao (2018) **"EFFECT OF DIFFERENT LEVELS OF FERTILIZERS AND NEEM CAKE ON SOIL HEALTH GROWTH AND YIELD OF POTATO (*SOLANUM TUBEROSUM* L.) CV. KUFRI JYOTI"** said that the field experiment was conducted to study the effect of different levels of fertilizers and Neem cake on soil health, growth and yield of Potato. The experiment was carried out in RBD (Randomised Block Design) with three replications for each treatment. The treatment combination was laid out as T0- Control, T1-NPK 0% Recommended Dose of Fertilizer (RDF)+ Neem cake 50 kg ha-1 T2- NPK 0% RDF+ Neem cake 100 kg ha-1, T3-NPK 50% RDF+ Neem cake 0 kg ha-1, T4-NPK 50% RDF+ Neem cake 50 kg ha-1, T5-NPK 50% RDF+ Neem cake 100 kg ha- 1, T6-NPK 100% RDF+ Neem cake 0 kg ha-1, T7-NPK 100% RDF+ Neem cake 50 kg ha-1, T8-NPK 100% RDF+ Neem cake 100 kg ha-1 respectively. Soil samples were taken from 0-15cm depth of soil randomly prior to tillage operations, air dried and passed through 2 mm sieve. Then the composite sample was taken for mechanical and chemical analysis. The findings of the experiment concluded that the application of NPK (@ 120 kg ha-1, 100 kg ha-1, 120 kg ha-1 and Neem cake @ 1250 kg ha-1 had significant effects on the soil, growth and yield of Potato which makes the combined application of NPK and Neem cake a beneficial approach towards an important source of plant nutrients. From economical point of view, the treatment T8 (NPK 100% RDF+ Neem cake 100 kg ha-1) was found to be economically viable in terms of gross return (Rs 325120.00 ha-1). It has been recorded that the maximum number of yield of 40.64 t ha-1was found in treatment T8 (NPK 100% RDF+ Neem cake 100 kg ha-1), followed by treatment T7 (NPK 100% RDF+ Neem cake 50 kg ha-1) with 33.03 t ha-1. And the minimum tuber yield was found in treatment T0 (Control) with 12.25 t ha-1. Application of both NPK and Neem cake resulted in significantly higher tuber yield as compared to Control.

From this, NPK and neem cake showed significant response in plant growth and neem cake manure protects plant roots from nematodes, soil grubs and white ants probably due to its residual limonoid content. It also acts as a natural fertilizer with pesticidal properties. Neem cake also reduces alkalinity in soil, as it produces organic acids on decomposition. Being totally natural, it is compatible with soil microbes, improves and rhizosphere micro flora and also enhances the fertility of the soil. Neem cake improves the organic matter of the soil, helping improve soil texture, water holding capacity, and soil aeration for better root development.

Rajesh and Arun Alfred David (2017) entitled as "**RESPONSE OF NEEM CAKE RHIZOBIUM AND INORGANIC FERTILIZER ON SOIL HEALTH GROWTH AND YIELD OF GREEN GRAM (*VIGNA RADIATA* L.) VAR. SAMRAT"** said that it was concluded from trial that the various level of N P K + Neem cake and *Rhizobium* used from in the experiment, the treatment combination T11(I2+N2+R1) @100% N P K ha-1 + @ 100% Neem cake 0.5 t ha-1 + @ 100% *Rhizobium* 20 g/ Kg seed was found to be the best treatment gave highest benefit of 58651with highest cost benefit ratio 1:2.73 for Green gram it could be recommended for profitable production of Green gram (*Vigna radiata* L.*)* var. The use of biofertilizers are more eco-friendly in nature. They can play a significant role in fixing atmospheric nitrogen; biofertilizers enrich soil fertility and improves soil fertility. Samrat, it improves soil physical and chemical properties. Integrated nutrient management is better for soil health and Green gram production. The composition of Neem cake is 5.2 % N, 1.0 % P, 1.4 % K. Neem cake act as a nitrogen inhibitor means reduce the nitrification. It supplies the available nitrogen for a long time in the soil (Katyayan, 2012). If we compare the pH of pre sowing soil sample which was 7.44 with that of after crop harvest soil, there was decrease in pH after crop harvest. Increasing dose of N P K and Neem cake lightly decrease pH of the post-harvest soil. The decrease in pH might be due to higher growth of crops as respiration is more. Respiration evolves carbon dioxide and reacts with water to form carbonic acid in soil.

From this, we concluded that the Neem cake is a potential source of organic manure. Neem has demonstrated considerable potential as a fertilizer. Our Neem cake also reduce alkalinity in soil, as it produce organic acid on decomposition, being totally natural, the Neem cake we offer hence ensure fertility of the soil, it also improve the organic matter contain of the soil, helping improvement in soil texture, water holding capacity, soil aeration for batter root development. The addition of Neem cake also positively affected the available soil organic carbon, N P K and Mn content of soil resulting better growth and grain yield of mung bean (*Vigna radiata* L.) besides suppressing soil borne pathogens. Organic carbon (%), available nitrogen, phosphorus and potassium (kg ha-1) were increased in soil after crop harvests. The chemical properties were significantly affected by different treatment combination of N P K, Neem cake and *Rhizobium*.

Hiral J. Jariwala, Huma S. Syed (2016) entitled as **"STUDY ON USE OF FRUIT PEELS POWDER AS A FERTILIZER"** said that Fruits contain a high amount of antioxidants that are beneficial to our health in many ways. The present study deals with the utilization of fruit peels for the effective growth of plants and higher yield, by mainly focusing on Nitrogen, Phosphorous and Potassium. Different fruit peels such as Pomegranate, Orange, Sweet lime and Banana were used. Generally, fruit peels are thrown in garbage and it goes to solid waste dumping site. That causes odor problem due to degradation of peel content in dumping site. These fruit peels have nutrients like potash, iron, zinc, calcium, citrate content etc. Fruit peel powders are used as natural fertilizer in the present study. Different formulation of fruit peel powder was used to compare the plant growth. Fruit peels were collected from fruit juice vendors were segregated first. So different fruit peels can be used on field as per requirements of pH and nutrients. Each formulation was mixed with water in different quantities. Each formulation was mixed with water in different quantities. 1g of fruit peel powder of citrate peels like pomegranate, orange, sweet lime were taken in 100 ml of distilled water and mixed thoroughly for the preparation of extract. This mixture was stirred for 3 days by using magnetic Stirrer. Same procedures are also done by Alkaline Banana peel powder and make solution. There are two types of fruit peel powder like a) citrate peel powder which consists of orange, sweet lime and pomegranate peel and b) alkaline peel powder consisting of banana peel. Both type of peel powder has different pH, generally alkaline peel powder is used for reducing acidity content present in soil. Similarly, acidic peel reduces salinity of soil. The final results of the study showed that Citric Peel powder has higher Nitrogen content(9.1 mg/g), whereas alkaline peel powder has higher quantity of Phosphorous(4.2 mg/g) and Potassium(2.1 mg/g).

This proves that the powder can be feasibly used as a Soil Fertilizer, pH regulator (for improving soil morphology) as micronutrient supplement (zinc, iron, calcium) and also for horticultural purposes. Both different peels are used for control pH of soil. Where citrate peel powder is used to decrease pH of soil and alkaline peel powder is used to increase pH of soil. By mixing of both citrate and alkaline peel powder we can reach up to maximum nutrient content. The use of fruit peel powder is pH regulator for soil, improve soil morphology, fulfils requirements of micronutrient, best use for Horticulture. These are cheapest and harmless materials are used for plant growth. The present study deals with the utilization of fruit peels for the effective growth of plants and higher yield.

A A Kadir, N A Rahman and N W Azhari (2016) entitled as *"***THE UTILIZATION OF BANANA PEEL IN THE FERMENTATION LIQUID IN FOOD WASTE COMPOSTING"** said the preparation for fermentation liquid is by using banana peel to replace fermented food and coconut candy to replace sugary water. Banana peel is an organic waste that highly rich in nutrient especially K, that could support the microbial growth in fermentation phase. Using banana peel as fermentation liquid or waste in composting is considered as good as it stimulates soil microbial growth and activity with the subsequent mineralization of plant nutrients. As replacement of brown sugar in common fermentation liquid, uses of candy which serves as food source for the microbes. Three litres of water was mixed with 250gram candy and 250gram banana peel from Makanan Ringan Mas. Fermentation was occurred when bubbles starts to form, which normally occurs on the second day. Ideally, fermentation should take no longer than 7 days. Fermentation liquid was completed when the banana peel floats and the liquid settles at the bottom. During the fermentation process, the lid of the bottle should be loosened once a day to remove the gas that trapped in the bottle. The sweet and sour smell produced indicates that the fermentation liquid is successfully conducted. The goal of this study was to compost the food waste generated at Makanan Ringan Mas and determine the physical parameters which are temperature, pH and chemical parameters which are Nitrogen (N), Phosphorous (P) and Potassium (K). The parameters which include temperature, pH value, NPK values has been examined. Banana peel is being used as the fermentation liquid whilst soil and coconut husk were used as the composting medium. Based on the results during the composting process, most of the pH value in each reactor is above 5 and approximately at neutral. As for NPK content Nitrogen value range is 35325 mg/L to 78775 mg/L, Phosphorus, 195.83 mg/L to 471 mg/L and potassium is 422.3 mg/L to 2046 mg/L which is sufficient to use for agricultural purpose.

This study also used to compare between NPK concentration produce from the composting process using banana peel as fermentation liquid with the chemical fertilizers. Reactor B showed the most effective composting process in this composting study. Reactor B which consists of banana peel waste is easily decomposed and the nutrient produced in compost is much faster and higher than others. This is probably due to the oxygen and supplementary nutrient supply that could promote specific growth of microorganism essential for mineralization of organic substance. High K and N content in banana peel compost reactor is to assist in obtaining high potential K and N nutrient source in the soil.

Monisha. J. N. and Dr. G. N. Rameshaiah (2016) entitled as "**PRODUCTION AND COMPARSION OF SOLID-LIQUID FERTILIZER FROM VEGETABLE WASTE"** said Vegetable wastes are produced in large quantities in the markets across the world, to make use of this waste and to reduce the pollution they can be used to produce Biofertilizers. The collected five vegetables were produced in large quantity because they are daily used in everyday life; they are subjected to decomposition (1month) for producing solid and liquid fertilizers. Since Biofertilizers are one of the best tools that is used in the agricultural field, which is applied as a replacement of conventional fertilizers. The nutrients present in the fertilizers were determined and comparative study was undertaken to evaluate Vegetable waste make an extraordinary measure of contamination which contain high part of natural matter that causes genuine ecological and wellbeing issues. Predetermined samples were taken to estimate the components like pH, moisture content, organic content, particle size followed by major components like nitrogen, potassium and phosphate, minor components like calcium and magnesium, sulfur and micro components like boron, manganese were also estimated. A different type of waste was collected and they were separated according to the requirement. The types of vegetable waste that are collected from market are varieties of green leaves, potato, tomato, beans and carrot as they are used in large quantities in day to day life. The collected samples were finely chopped and grounded with the help of mixer and they were kept in separate bins for solid and liquid fertilizer. For solid fertilizer the 500grams of each sample were added containing ½ kg of soil in it and allowed for decomposition. For liquid fertilizer 500grams of each sample were added and approximately 3litres of water was added depending upon the requirement and they were subjected to aerobic decomposition process for 1month. The liquid fertilizer sample was filtered and centrifuged at 10,000 rpm for 10 minutes and stored for further analysis. The fertilizer sample is of its suitable characteristics which should be sealed tightly and then stored at room or cold temperature. Samples are stored in tightly sealed containers.

The present work is carried out to explain the uses of Biofertilizers that are produced naturally from the vegetable waste which are produced in two different ways and its comparison to select the better source for further application. Hence forth using natural composts or Bio fertilizers will help in retaining the soil properties and produce organic food crops which does not have any side effects.

Dr. Asha V. Pillai, Aswathy, K. K., Preethy, T. T. and Renisha, Mannambeth (2016) entitled as **"EFFECT OF ORGANIC LIQUID MANURES ON CROP GROWTH AND PRODUCTIVITY"** said Unscientific use of chemicals in agriculture leads to several health hazards and environmental problems. India has vast potential of organic resources and the extract prepared from these resources can be effectively utilized to sustain yield, improve physical, chemical and biological properties of soil and to maintain soil health. Commonly used liquid manures are compost tea, vermiwash, biogas slurry and cow's urine along with the extracts of oil cakes like groundnut cake, poultry manure and neem cake. The nutrient content of cow's urine was reported to be 0.9 - 1.2% N, 0.2 – 0.5% P and 0.5-1% K. The combined use of neem cake (0.5 t ha-1) as soil application and foliar application of vermiwash (1:1 ratio) increased the crop vigour and fruit yield of chilli (George, 2006). Ingham (2003) observed that compost tea contained soluble nutrients that enhanced crop yield. The beneficial organisms present in the EM solution increased the yield of crops (Yamada *et al*., 2003). Sayre (2010) reported that application of compost tea at fort nightly interval increased the marketable yield of potato by 18 to 19 %.Compost tea could reduce the severity of diseases like powdery mildew and downy mildew of grape, grey mould of strawberries and late blight of potato (Elad *et al.,* 1994); butter cup infestation and tomato blight (Touart, 2000). Scheuerell *et al.* (2002) observed that compost tea as foliar spray reduced the incidence of pests and diseases in crops by competition with disease causing microbes and degradation of toxic pesticides. The effectiveness of compost tea in controlling the bacterial spot of tomato was reported by (Al-Dahmaniel *et al*., 2003). According to Sayre (2003), compost tea had the capacity to manage many pests and diseases of crop plants. Ingham (2005) reported that the compost tea contained populations of several beneficial microorganisms and also the well made compost tea will be dominated by beneficial bacteria or fungi.

From this, it can be concluded to protect our crops and the environment we have to follow sustainable and eco-friendly agriculture. Among the several methods of ecofriendly agriculture, liquid nutrition occupies an important position. Foliar nutrition with organic compounds in vegetables is especially important as they provide quality foods, which are very important for providing health security to people. And the observation shows that greater the amount of soluble material in the compost tea, the more food resources would be there for the growth of beneficial bacteria and fungi, and microbial activity will be improved.

Mercy S, Mubsira Banu S, Jenifer (2015) entitled as **"APPLICATION OF DIFFERENT FRUIT PEELS FORMULATIONS AS A NATURAL FERTILIZER FOR PLANT GROWTH"** said that Fruit peels of Banana, Pomegranate, Sweet lime and Orange are highly rich in potash, ion, zinc etc. Three different formulations were applied for plant growth in two methods such as fruit peel powder, fruit peel powder extract as a natural fertilizer. Fenugreek seeds were used to test the utilization of fruit peel powder as a natural growth enhancer. After 45 days of application of fertilizer, plant growth was measured and the yield of fenugreek vegetables was counted. Among the three formulations of fruit peel powder and fruit peel extract, formulation 1 was found more suitable for plant growth. Control soil, fruit peel fertilized- both powder and extract applied soil samples were analyzed for the nutritive values of soil. Nitrogen, Phosphorous, Potassium were mainly observed. After the application of three different formulations in soil, soil fertility is increased. The soil was fertilized with different formulation of fruit peel powder. After 15days of application of fruit peel powder. The seeds of fenugreek (*Trigonella foenum graecum*) were sown in fertilized soil which was already fertilized by formulation of fruit peel. Control was maintained without formulation. After 45 days of seedling the plant length was measured for control and test. Control was maintained without formulation. Length of the plant was very less in control than the fruit peel powder applied soils. The collected soil was taken separately and filled with many pots. Each pot contains 4 kg of soil. The soil samples were air-dried and the dried soil was packed in sterile polythene bags and sent to soil quality centre, collected fruit peels were washed thoroughly with tap water to remove the unwanted material including seeds. The washed peels were cut into small pieces [1-5 cm] and air dried in sunlight for 20 days. The dried fruit peels were powdered individually, sieved and stored at room temperature. Different formulation of fruit peel powder was used to compare the plant growth. Each formulation was mixed with water in different quantities. 1g of fruit peel powder of pomegranate, orange, sweet lime, banana was taken in 100 ml of distilled water and mixed thoroughly for the preparation of extract. This mixture was stirred for 3 days by using magnetic stirrer.

From this, we concluded that the fruit peel powder extract increased the growth of plants and yield and the leaves of the plants were remaining green till harvesting. Additionally, growth of microorganisms was also increased by the application of fruit peel powder and extract. And the chemical fertilizers can be replaced by the fruit peel powder and extract to protect the soil from the infertility.

Asha V. Pillai and Sheela K. R (2015) entitled as **"ORGANIC LIQUID MANURES AS FOLIAR NUTRIENT SUPPLEMENT IN AMARANTHUS"** said the liquid manures were prepared by soaking composite organic manures in water (1:5 ratio), collecting the extract seven days after soaking and enriching the same with PGPR addition. Among the combinations, the extracts of composite manure prepared by mixing groundnut cake, neem cake and poultry manure (in 1:0.5:0.5 ratio), groundnut cake, vermicompost and poultry manure (in 1:0.5:0.5 ratio), and groundnut cake and poultry manure (in 1:1 ratio) recorded high nitrogen content (0.56-0.78%). Foliar application of these liquid manures as substitute to nitrogen for top dressing in amaranthus enhanced plant height, number of leaves per plant, crop yield and vitamin C content. The basal application of farmyard manure along with full P and K and half nitrogen was applied uniformly for all treatments. Organic liquid manures (T1 to T3) were prepared by mixing composite manures with five times water and the liquid extract was collected after seven days. After each harvest a foliar spray was given. Four harvests could be obtained from the crop. Observation on growth characters like plant height, number of leaves, total dry matter production and yield and quality attribute like Vitamin C were recorded. Use of foliar formulations is gaining importance in crop production owing to its quick response in plant growth. It is proved to be the fastest way of curing nutrient deficiencies and boosting plant performances at specific physiological stages. The result revealed that the use of (groundnut cake + neem cake + poultry manure) can be used as a substitute to top dressing of nitrogen in Amaranthus. The significance of organic N nutrition in enhancing the vitamin C content of amaranthus. Though the N content of the best liquid manure T3 is lesser than 2% foliar applied urea, the presence of invitro beneficial microorganisms might have enhanced the biological efficiency of the crop plants resulting in improved crop quality.

From this literature, we conclude that the organic liquid manures contain several beneficial microbes which help to increase yield, impart resistance to diseases, insects, pests, improve drought tolerance and enhance crop quality. Organic liquid fertilizer is considered as a viable means for enhancing crop production both in conventional and modern production system. Organic manures play a key role in sustaining crop growth and productivity and this is very important in vegetable cultivation. Among the organic manures, groundnut cake, vermicompost, neem cake, poultry manure and compost are considered to be viable choice in crop production on account of their high nutrient content.

CHAPTER 3

METHODOLOGY

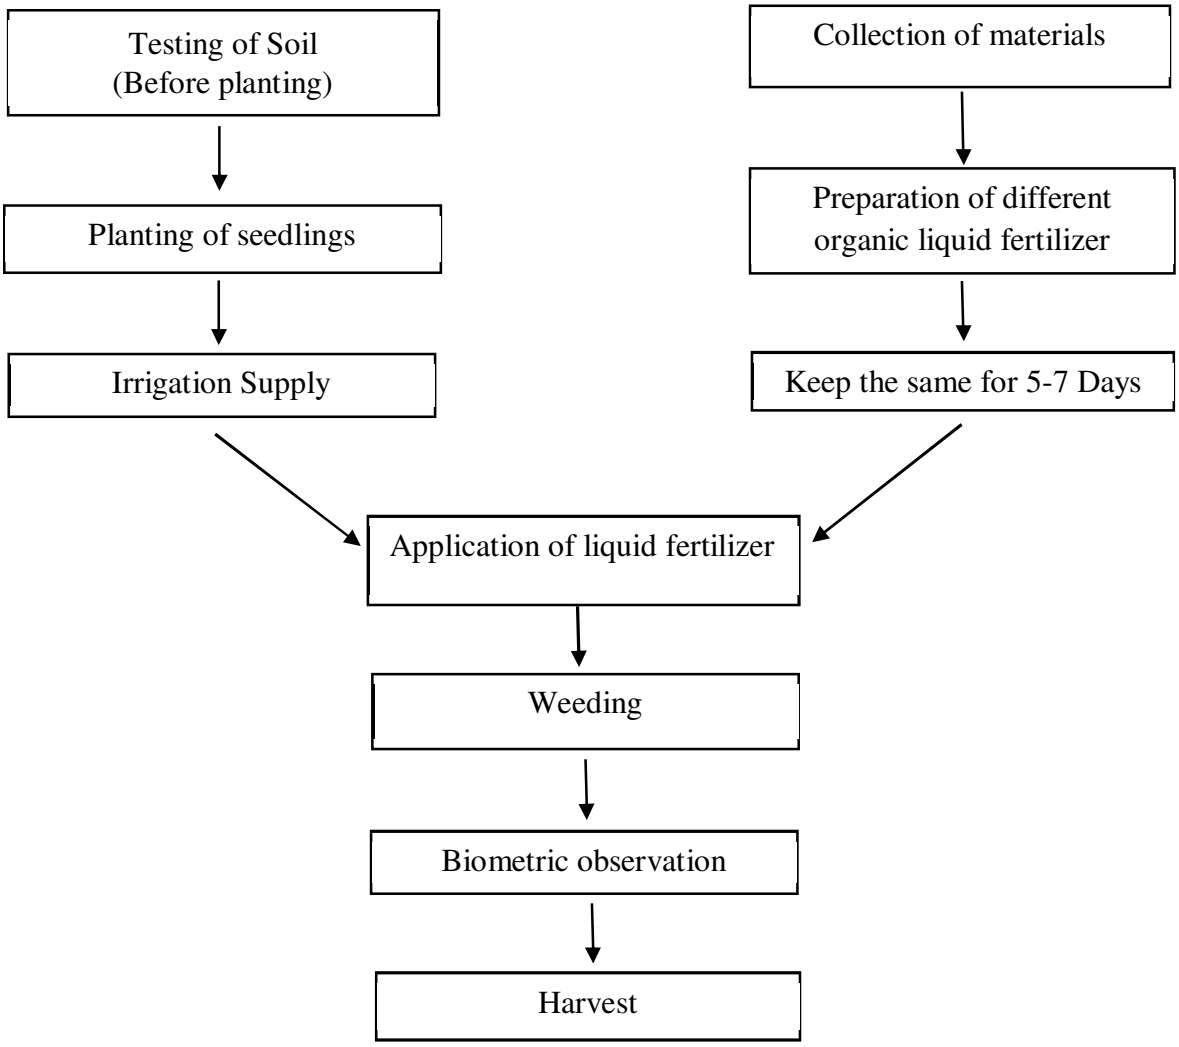

FIGURE 3.1 METHODOLOGY FLOW CHART

3.1 TESTING OF SOIL

Before planting the seedlings, the soil sample was collected at the field of Paavai Engineering College at Namakkal located on latitude 11.2195158 and longitude 78.1677931. The parameters like soil pH, Electrical conductivity (EC), Organic Carbon, Nitrogen, Phosphorus and Potassium (soil nutrients) were tested in the laboratory.

3.2 PLANTING THE SEEDLINGS

Planting two seedlings per hill in the polybag and then thin one plants per hill after 10 days. It consists of 5 treatments with two replications. Planting can be done during November - December. The optimum time of seed sowing varies greatly depending upon climate, varieties and their temperature requirement for growth.

FIGURE 3.2 AT THE TIME OF PLANTING THE SEEDLING

FIGURE 3.3 AT 30 DAP

3.3 IRRIGATION SUPPLY

Irrigation is done at weekly intervals. A pre-sowing irrigation 3-4 days before sowing is beneficial. Give pre-sowing irrigation, if the soil is not moist enough. During summer, irrigate the crop at intervals of 2 to 3 days.

3.4 COLLECTION OF MATERIALS

The different materials are Banana peel, Tea powder waste, Cow dung, Coconut cake, Neem cake, Groundnut cake, Vegetable waste. The materials were collected for preparing the liquid fertilizer and these are easily available waste materials.

3.5 PREPARATION OF LIQUID FERTILIZERS

The liquid fertilizers were prepared with different ratios of organic materials and the preparation details are explained below.

3.6 APPLICATION OF LIQUID FERTILIZER

Liquid fertilizers can be applied at every 30 days intervals (i.e. 30 DAP, 60 DAP, 90 DAP, 120 DAP and 150 DAP) and the observation of plant growth can be recorded.

3.7 WEEDING

Weeding is the process to remove out the weeds. Weeds are unwanted plants which grows along the useful crops. Weeding is required because weeds are competitive plants as they reduce the useful crop yield by acquiring space, fertilizers and nutrients from the soil. Hand weeding can be done at every 15 days interval.

3.8 BIOMETRIC OBSERVATION

3.8.1 GROWTH ATTRIBUTES

Different parameters of growth attributes such as plant height, leaf length, leaf breadth and number of leaves present in the plant was recorded at 30 DAP, 60 DAP, 90 DAP, 120 DAP and 150 DAP.

3.8.2 YIELD

Production in each treatment was recorded and expressed in gram. It requires good amount of fertilizers for high yield. The fertilizer dose depends upon the fertility of soil.

3.9 HARVEST

FIGURE 3.4 AT HARVESTING STAGE OF BRINJAL

Harvesting can be done at 70 to 85 days from transplanting. Brinjals are ready for harvest when the fruit is glossy, firm, full-coloured. Usually picking can be done once in each week; twice each week at the peak of the season. Frequent picking promotes fruit development and prevents the pods from growing too large.After harvesting of brinjal, the performance of organic liquid fertilizers was analyzed through the observation of plant growth and also based on the soil testing parameters like pH, EC, NPK and organic carbon.

CHAPTER 4

MATERIALS AND ITS PROPERTIES

4.1 BANANA PEEL

FIGURE 4.1 BANANA PEEL

It is the outer covering of banana fruit. A banana peel is also called as banana husk or banana skin. Banana peels contain nutrients that are essential for healthy potted plants. Bananas are a great source of potassium and phosphorus. Their peels also contain the same elements which work wonders for plants. These peels actually decompose quickly and provide necessary nutrient to the plants.

4.1.1 PROPERTIES

- Banana peel as a growth booster for plants.
- Banana peel has a fantastic source of potassium which is about 42%.
- It contains potassium, phosphorus, calcium, magnesium, sodium, manganese and sulphur.
- Using banana peels in the garden provides nutrients that plants need to thrive, and it acts also as a pest repellent.
- Banana peels also contain calcium, which helps plants take up more nitrogen, which some potassium loving plants need.

4.1.2 TREATMENT PROCESS (BANANA PEEL FERTILIZER)

- Take the banana peels and Chop the peels.
- Take some amount of tea powder waste.
- Add 1 litre of water and cover the container or bottle.

- Keep the same for 7 days. Stir the mixture once every three days.
- Mix with same amount of water and apply to the plants.
- Working cut up banana peels into the soil surrounding your plants not only feeds the plants, it also will help naturally deter green aphids and other pests. You can also spray your banana peels compost tea directly onto plants to help repel aphids.

4.2 TEA POWDER

FIGURE 4.2 TEA POWDER WASTE

Tea powder can be a great source of biodegradable garbage but it can make a good source of compost as well. By using this compost, the plants grow very rapidly and there is increment in the leaf area, leaf density, height, and germination period and germination frequency of the plant. It acts as a fertilizer and help to improve the plants growth, overall health and vigour.

4.2.1 PROPERTIES

- Tea waste powder is a good fertilizer for plant growth.
- It contains nutrients and trace minerals that promote healthy growth in plants.
- The evidence dried leaves contain about 4.4% nitrogen,0.24% phosphorus and 0.25% potassium.
- Create a more fertile environment for the plants.
- It increases the nutrient levels and improve the soil quality as they decompose.

4.3 COW DUNG

Cow dung is the undigested residue of plant matter which has passed through the animal's gut. The resultant faecal matter is rich in minerals. Cow dung contains a substance similar to penicillin, which has a disinfecting effect and reduces bacteria that cause disease.

FIGURE 4.3 COWDUNG

Cow dung is high in organic materials and rich in nutrients. It contains about 3 percent nitrogen, 2 percent phosphorus, and 1 percent potassium (3-2-1 NPK). In addition, cow manure contains high levels of ammonia and potentially dangerous pathogens.

4.3.1 PROPERTIES

- Cow manure is rich in minerals, especially nitrogen, phosphorus, and potassium.
- It can support the growth of beneficial microorganisms when it's mixed with soil.
- Manure can also improve the texture of the soil and help it to maintain moisture.
- It contains about 3% Nitrogen, 2% phosphorus and 1% potassium (3-2-1 NPK).
- In addition, cow manure contains high level of ammonia and potentially dangerous pathogens. For this reason, it is usually recommended that it be aged or composted prior to its use as cow manure fertilizer.

4.3.2 TREATMENT PROCESS (COWDUNG FERTILIZER)

- Place the cow dung into the bucket and add 1 lit of water, stir the mixture once for first 3 days and apply to the plants.
- Use a drum, bucket, or other suitable container. It must have a lid or a makeshift lid.
- Place the dried-out cow manure into the container. Place in to about one-third of the container's height.
- Fill the rest of the container with water.
- Cover the container. This keeps out the flies and other pests.
- Stir the mixture once every three days. Or, stir once a day for the first three days and then only stir weekly.

- Leave until the smell dissipates. Once it doesn't smell anymore, it is ready for use. The odor may be smelly over the container itself but the ammonium odor should be completely gone. If not, leave longer until it has gone.

4.4 COCONUT CAKE

FIGURE 4.4 COCONUT CAKE

Coconut Oil Cake is the by-product of Oil Extraction. Coconut Oil Cake is the residue left after the extraction of oil from copra which is mainly used as manure for plants and also as cattle feed. You have to use with Neem Cake or any other natural insect repellent. Coconut Oil Cake contains 4-5 per cent oil which is extracted by solvent extraction process.

4.4.1 PROPERTIES

- Oil cake is one of the natural fertilizer with high nitrogen content, which is the residues of coconut.
- It is mainly used as a manure for plants.
- It is very effective when it can be use with neem cake or any other natural insect repellent.

4.4.2 TREATMENT PROCESS (COCONUT CAKE FERTILIZER)

- Take 200gms of coconut cake and 100gms neem cake into the bucket.
- Add 1 litre of water and cover the bucket perfectly.
- Keep the same for 2-3 days or leave it until the smell dissipates.
- Filter the liquid from the mixture.
- Now mix the liquid with 1-2 times of water.
- Apply the liquid fertilizer to the plants at every 30 days interval.

4.5 GROUNDNUT CAKE

FIGURE 4.5 GROUNDNUT CAKE

Groundnut Oil Cake is made by extracting the oil completely from the groundnut seeds. The left over is then processed to produce high quality Groundnut Oil Cake. Oilseed cakes are the by-products generated from edible oil processing. The oilseed cakes are generally used as animal feed, plant fertilizer or soil compost due to their high protein, carbohydrate, mineral and nitrogen contents.

4.5.1 PROPERTIES

- Groundnut cake is rich in nitrogen (7.3%) and facilitates better growth of plants.
- Also, it contains phosphorus (1.5%) and potash (1.3%) enables flowering and higher yield in plants.
- Peanut cake is a very effective way to grow your veggies organically.
- This helps in improving the health of plants and thus enhance the crop yield.
- It is often used to boost the growth of fruit, flower and vegetable crops.
- Groundnut cake increase the water holding capacity of soil and soil structure.
- Don't apply directly into soil, mix with neem cake fertilizer it to prevent from ant and neem also good biofertilizer, bioinsecticide.

4.5.2 TREATMENT PROCESS (GROUNDNUT CAKE FERTILIZER)

- Take 200gms of ground nut cake and 100gms neem cake and put it in 1 lit of water, 100ml of curd.
- Add jaggery and it acts as a good promoter to increase the absorption of nutrients by plants.
- Keep the same for 2-3 days.
- After 2-3 days you can take that and mix with 1-2 times of water and apply to the plants.

4.6 NEEM CAKE

FIGURE 4.6 NEEM CAKE

Neem cake organic manure is the by-product obtained in the process of cold pressing of neem tree fruits and kernels, and the solvent extraction process for neem oil cake. It is a potential source of organic manure. Neem cake organic manure protects plant roots from nematodes, soil grubs and white ants probably due to its residual limonoid content. It also acts as a natural fertilizer with pesticidal properties.

4.6.1 PROPERTIES

- Neem Cake is used as an organic fertilizer because of the various micro and macro nutrients which it is composed of.
- It will provide a better crop yield because it will provide the nutrients that crops need.
- It helps to cure diseases and will control the growth of nematodes and harmful plant pathogens.
- The crop yield is15-25% higher when using Neem Cakes than with any other fertilizer.
- It will also inhibit nitrification of the soil plus enhance the efficiency of nitrogen providing fertilizer.
- The use of Neem Cakes will increase the water holding capability of the soil and improve soil structure.

4.7 VEGETABLE WASTE

Vegetable wastes include the rotten, peels, shells, and scraped portions of vegetables or slurries. These wastes can be treated for biofuel production through fermentation under controlled conditions or else used for composting. The natural decomposition of wastes by microbes generates products with high humus content.

FIGURE 4.7 VEGETABLE WASTE

4.7.1 PROPERTIES

- Vegetable waste provides good amount of nutrients for during harvesting.
- It contains major nutrients like NPK and also provides micronutrients to the plant.
- The microorganisms and the nutrients present in the raw materials are very helpful in improving soil health.
- Vegetable waste compost can increase water and nutrient holding capacity of sandy soils, increase aeration and internal drainage of clay soils, add nutrients, increase soil microorganisms, and suppress some plant diseases.
- The vegetable waste containing lettuce and onion waste has high amounts of sulphur 0.2% and 0.7% respectively, their moisture content is of 96.2% and 91.1% respectively.

4.7.2 TREATMENT PROCESS (VEGETABLE WASTE FERTILIZER)

- Put the vegetable waste into the bucket, add certain amount of sugar.
- Cover the bucket.
- After 2-3 weeks, discharge the brown liquid.
- Then mix the brown liquid with 1-2 times of water and apply to the plants.

CHAPTER 5
RESULT AND DISCUSSION

5.1 GROWTH ATTRIBUTES

5.1.1 PLANT HEIGHT

The average height of plants from each replication was measured with a measuring scale and results were expressed in centimetres. The plant height of selected plants was recorded at 30 days interval in each replication of different treatments. The plant height was recorded from the bottom of the plant to the highest leaf of the individual plant. The plant height recorded at 30 DAP, 60 DAP, 90 DAP, 120 DAP and 150 DAP. From this observation, maximum plant height was observed in groundnut cake treatment (89cm) followed by coconut cake (85cm) and the minimum plant height (74cm) in control treatment.

5.1.2 LEAF LENGTH

The average length of randomly selected leaves from each replication was measured in cm. The leaf length of the plant was recorded at 30 DAP, 60 DAP, 90 DAP, 120 DAP and 150 DAP. From this observation, maximum leaf length was observed in groundnut cake fertilizer (16.5cm) and the minimum leaf length (14 cm) in control treatment.

5.1.3 LEAF BREADTH

The average breadth of randomly selected leaves from each replication was measured in centimetre and the measurements are recorded at 30 days interval. The maximum breadth (12 cm) was measured under groundnut cake fertilizer whereas the lowest (10 cm) was scored under control treatment and the measurements of leaf breadth in each treatments were showed below.

5.1.4 LEAF COUNT

The average number of leaves were recorded in each treatment and results were expressed as leaf number per plant. Leaf count was observed at 30 DAP, 60 DAP, 90 DAP, 120 DAP and 150 DAP. More number of leaves formed under groundnut cake, coconut cake and control treatment were 180, 176 and 168 respectively.

5.1.5 YIELD

The total fruit production in each treatment was recorded and yield was expressed in kilogram. It has been recorded that the higher yield of 2.10 kg was found at groundnut cake treatment, whereas lower yield 1.50 kg was recorded at control treatment. Application of different organic liquid fertilizer had resulted significantly higher yield as compare to control treatment.

TABLE 5.6 ANALYSIS OF SOIL PROPERTIES AFTER HARVEST OF BRINJAL

Soil pH

Soil pH is a measure of the acidity or basicity of a soil. The normal pH suitable for plant growth ranges from 6.5 – 7.5. The result shows that the highest pH (7.7) was recorded with control treatment followed by vegetable waste treatment (7.20) whereas the lowest value was observed with groundnut cake treatment(6.82).

Electrical Conductivity (dSm^{-1})

Soil Electrical conductivity is a measurement that correlates with soil properties which includes soil texture, cation exchange, drainage conditions, organic matter level, salinity and subsoil characteristics. Too low EC levels indicate low available nutrients, and too high EC levels indicate an excess of nutrients.

The maximum Electrical conductivity (EC) value 0.58 dSm^{-1} was found at groundnut cake treatment and the minimum electrical conductivity value 0.0033 dSm^{-1} was recorded in control treatment. The application of various fertilizers raised the EC of the soils and the highest was recorded at treatment receiving the dose of organic fertilizers.

Organic Carbon (%)

The result shows that maximum soil organic carbon (OC) of 0.58 % was observed in groundnut cake treatment and the minimum soil organic carbon of 0.38 % was recorded in control treatment.

Available Nitrogen (kg ha-1)

The maximum available Nitrogen of 284.00 kg ha^{-1} was recorded at groundnut cake fertilizer treatment and the minimum available Nitrogen was recorded at control treatment with 258.00 kg ha^{-1}.

Available Phosphorus (kg ha-1)

The maximum available Phosphorus of 29.6 kg ha^{-1} was recorded at groundnut cake fertilizer treatment and the minimum available Phosphorus was recorded at control treatment with 15.9 kg ha^{-1}.

Available Potassium (kg ha-1)

The maximum available Potassium of 163 kg ha^{-1} was recorded at groundnut cake fertilizer treatment and the minimum available Potassium was recorded at control treatment with 106 kg ha^{-1}.

CHAPTER 6

CONCLUSION

From the result, it can be concluded that the application of fertilizer showed that the plant height, leaf length, leaf breadth, leaf count and yield was higher in groundnut cake and followed by coconut cake treatment whereas the minimum growth was observed in control treatment . The application of fertilizer treatment had significant effects on the soil, growth and yield of brinjal and it makes a beneficial approach towards an important source of plant nutrients in the soil.

Observations on plant growth showed that the Brinjal plants in groundnut and coconut cake treatments were generally tall, more vigorous and reached 50% flowering earlier than in the control treatment. And the use of these cakes reduces the alkaline content in the soil because when they decompose, this produces organic acids. It is very low cost process to convert waste resources into organic liquid fertilizer.

These fertilizer treatments make a good addition to the soil and it makes the soil rich and ideal for plant growth. The utilization of organic liquid fertilizer in proper way not only useful in increasing soil fertility but also decrease pollution load and increase greenery, it is proving to be beneficial for human being as well as for nature. And it is an effective tool to improve the physio - chemical and biological properties of the soil with higher yield of plants in a sustained way without affecting the fertility of soil.

ABSTRACT

Dairy farming is the important allied sector of agriculture and it has been a major sources of food, nutrition, income and livelihoods for hundreds of millions of people around the world. In the recent years with advancement in monitoring and automation technology, research in cattle rearing has resulted in development of production technologies that improved the quality and quantity of the milk, thus leading to improvement and increasing of milk production. India is a subcontinent hence it experiences a varied change in the temperature. Thus it creates an unfavourable condition for the dairy cattle. It leads to a problem called heat stress. It reduce their feed intake, then affect the fertility rate and finally lead to the decrease in the milk production. Hence we use a temperature sensor to find the surrounding temperature of the stanchion barn, when the temperature level is above to the fixed level it will trigger the relay to switch ON, the water will be sprayed in the form of mist. The mist form of the water will mixed with the surrounding air and tend to reduce the temperature. When the temperature reaches below the fixed level the will switch OFF the pump. The ambient temperature for the cattle growth is 19 – 21^{o} C. Cleaning the shed by pressurized water and water feeding to the cattle in regular intervals by coding on Arduino board. This system can be implemented at any small size dairy barn at low cost. It can be solution for the problems in the Indian dairy farms.

Key Words: *Heat Stress, Temperature, Automation.*

CHAPTER 1

INTRODUCTION

1.1 GENERAL

Agriculture is said to be the backbone of Indian economy. However, every Indian farmer own a cow in order to earn an additional income and meet the nutritional requirements of the family. In India farmers did not do any special arrangements for the cow rearing, mostly the stanchion barn will be the part of their house wall. Hence, it can be stated that dairy cows are the part of their family and even it considered the part of their spiritual belief. India has the tremendous milk production in the last 40 years and has become the largest milk-producing nation among the world countries due to its liberalisation in this field. India is known as the 'Oyster' in the global milk industry.

India has 37 pure cattle breeds, out of this Sahiwal, Gir, Red Sindhi, Tharparker, Rathi are known for their milking powers. In addition, few others such as Kankerj, Ongole and Hariana are known as dual breeds they are both the milking and draught qualities. Under good management conditions, the Red Sindhi averages over 1700 kg of milk after suckling their calves but under optimum conditions there have been milk yields of over 3400 kg per lactation. Hence, India is a sub-continent it experience a varying temperature all through the year, it leads to result in heat stress in the cattle. An automated system was developed to monitor the temperature change and to reduce it to normal.

1.2 OBJECTIVE

The main objective is to develop the cost-efficient automated system, which requires less maintenance work. The dairy farm i.e., cattle rearing is done in India as an additional income work. The feeds to the cattle is given the fodder that grown in the field and the residual remain in the field after the harvest of the crop. India is the sub continental country where it experiences a high temperature every year. At the time of the high temperature, the dairy cows get affected. As the global warming increases, there will be constant increase in the temperature day by day. Indian farmers won't have enough time to look into the matter.

- Due to the increase in the temperature, the cows are prone to the heat stress. The heat stress affect the feed intake of the cow then soon reduces the

milking rate and affect the fertility of the cows. This system can help in the monitoring temperature and control it by an automated system. It is a pre-programmed microcontroller, which senses the temperature with the help of the temperature sensor and guides the fogger system to switch ON automatically and automatically switched OFF when the temperature is normal.

- Cleaning the shed by pressurized water with submerged pump automatically with the help of Arduino IDE program. It has the relay to control the fluctuations and the water has pumped 2hrs interval the cow dung was converted into liquid by pressurized manner. It leads to keep clean shed.
- Water feeding is necessary for cows to stabilize the body temperature and producing the milk. Water feeding for cows should be in time and perfect interval for that we made the automation system for water feeding to the cows in the interval of 4hrs, 4hrs and 16hrs automatically the water cup has filled in 3minutes. By this method, the water has feed interval is perfect and there is no human to work.

1.3 DAIRY FARM AND DAIRY FARMING

1.3.1 Dairy Farming

Dairy farming is a class of agriculture for long-term production of milk, which is processed (either on the farm or at a dairy plant, either of which may be called a dairy) for eventual sale of a dairy product. While cattle were domesticated as early as 11,000 years ago as a food source and as beasts of burden, the earliest evidence of using domesticated cows for dairy production is the seventh millennium BC - the early Neolithic era - in north western Anatolia. Dairy farming developed elsewhere in the world in subsequent centuries: the sixth millennium BC in east Europe, the fifth millennium BC in Africa, and the fourth millennium BC in Britain and Northern Europe.

Dairy cattle housing systems vary greatly throughout the world depending on the climate, dairy size, and feeding strategies. Housing must provide access to feed, water and protection from relevant environmental conditions. One obvious issue for humanely housing cattle is temperature extremes. Heat stress can decrease fertility and milk production in cattle. Providing shade is a very common method for reducing heat stress. Barns may also incorporate fans or tunnel ventilation

into the architecture of the barn structure. Overly cold conditions, while rarely deadly for cattle, cause increases in maintenance energy requirements, thus increased feed intake, and decreased milk production.

During the winter months, where temperatures are low enough, dairy cattle are often kept inside barns, which are warmed by their collective body heat. Feed provision is also an important feature of dairy housing. Free stall barns and open lots are intensive housing options where feed is brought to the cattle at all times of year. Free stall barns are designed to allow the cows freedom to choose when they feed, rest, drink, or stand. They can be either fully enclosed or open-air barns again depending on the climate. The resting areas, called free stalls, are divided beds lined with anything from mattresses to sand. In the lanes between rows of stalls, the floor is often make of grooved concrete. Most barns open onto uncovered corrals, which the cattle are free to enjoy as the weather allows. Open lots are dirt lots with constructed shade structures and a concrete pad where feed is delivered.

1.3.2 Dairy Cattle

Cows

Dairy cattle (also called dairy cows) are cattle cows bred for the ability to produce large quantities of milk, from which products are made. Dairy cows generally are of the species *Bos taurus*. Historically, there was little distinction between dairy cattle and beef cattle, with the same stock often being used for both meat and milk production. Today, the bovine industry is more specialized and most dairy cattle have been bred to produce large volumes of milk. Either dairy cows may be found in herds or dairy farms where dairy farmers own, manage, care for, and collect milk from them, or on commercial farms. Herd sizes vary around the world depending on landholding culture and social structure. The United States has 9 million cows in 75,000 dairy herds, with an average herd size of 120 cows. The number of small herds is falling rapidly with the 3,100 herds with over 500 cows producing 51% of U.S. milk in 2007. The United Kingdom dairy herd overall has nearly 1.5 million cows, with about 100 head reported on an average farm. In New Zealand, the average herd has more than 375 cows, while in Australia, there are approximately 220 cows in the average herd.

FIGURE. 1.1. COWS AT STANCHION BARN

The United States dairy herd produced 84.2 billion kilograms (185.7 billion pounds) of milk in 2007, up from 52.9 billion kilograms (116.6 billion pounds) in 1950, yet there were only about 9 million cows on U.S. dairy farms—about 13 million fewer than there were in 1950. The top breed of dairy cow within Canada's national herd category is Holstein, taking up 93% of the dairy cow population, have an annual production rate of 10,257 kilograms (22,613 pounds) of milk per cow that contains 3.9% butter fat and 3.2% protein. Dairy farming, like many other livestock raring, can be split into intensive and extensive management systems.

Intensive systems focus towards maximum production per cow in the herd. This involve formulating their diet to provide ideal nutrition and housing the cows in a confinement system such as free stall or tie stall. These cows are housed indoors throughout their lactation and may be put to pasture during their 60-day dry period before ideally calving again. Free stall style barns involve cattle loosely housed where they can have free access to feed, water, and stalls but are moved to another part of the barn to be milked multiple times a day. In a tie stall system, the milking units are brought to the cows during each milking. These cattle are tethered within their stalls with free access to water and feed are provided. In extensive systems, cattle are mainly outside on pasture for most of their lives. These cattle are generally lower in milk production and are herded multiple times daily to be milked. The systems used greatly depends on the climate and available land of the region of which the farm is situated.

To maintain lactation, a dairy cow must be bred and produce calves. Depending on market conditions, the cow may be bred with a "dairy bull" or a "beef bull." Female calves (heifers) with dairy breeding may be kept as replacement cows for the dairy herd. If a

replacement cow turns out to be a substandard producer of milk, she then goes to market and can be slaughtered for beef. Male calves can either be used later as a breeding bull or sold and used for veal or beef. Dairy farmers usually begin breeding or artificially inseminating heifers around 13 months of age. A cow's gestation period is approximately nine months. New born calves are removed from their mothers quickly, usually within three days, as the mother/calf bond intensifies over time and delayed separation can cause extreme stress on both cow and calf.

Domestic cows can live to 20 years; however, those raised for dairy rarely live that long, as the average cow is removed from the dairy herd around age six and marketed for beef. In 2014, approximately 9.5% of the cattle slaughtered in the U.S. were culled dairy cows: cows that can no longer be seen as an economic asset to the dairy farm. These animals may be sold due to reproductive problems or common diseases of milk cows such as mastitis and lameness.

Calf

Most heifers (female calves) are kept on farm to be raised as a replacement heifer, a female that is bred and enters the production cycle. Market calves are generally sold at two weeks of age and bull calves may fetch a premium over heifers due to their size, either current or potential. Calves may be sold for veal, or for one of several types of beef production, depending on available local crops and markets. Such bull calves may be castrated if turnout onto pastures is envisaged, to make them less aggressive. Purebred bulls from elite cows may be put into progeny testing schemes to find out whether they might become superior sires for breeding. Such animals can become extremely valuable.

Most dairy farms separate calves from their mothers within a day of birth to reduce transmission of disease and simplify management of milking cows. Studies have been done allowing calves to remain with their mothers for 1, 4, 7 or 14 days after birth. Cows whose calves were removed longer than one day after birth showed increased searching, sniffing and vocalizations. However, calves allowed to remain with their mothers for longer periods showed weight gains at three times the rate of early removals as well as more searching behaviour and better social relationships with other calves. After separation, some young dairy calves subsist on commercial milk replacer, a feed based on dried milk powder. Milk replacer is an economical alternative to feeding whole milk

because it is cheaper, can be bought at varying fat and protein percentages, and is typically less contaminated than whole milk when handled properly. Some farms pasteurize and feed calves milk from the cows in the herd instead of using replacer. A day-old calf consumes around 5 litres of milk per day.

FIGURE. 1.2. CALF

Cattle are social animals; their ancestors tended to live in matriarchal groups of mothers and offspring. The formation of "friendships" between two cows is common and long lasting. Traditionally individual housing systems were used in calf rearing, to reduce the risk of disease spread and provide specific care. However, due to their social behaviour the grouping of offspring may be better for the calves' overall welfare. Social interaction between the calves can have a positive effect on their growth. It has been seen that calves housed in grouped penning were found to eat more feed than those in single pens, suggesting social facilitation of feeding behaviour in the calves. Play behaviour in pre-weaned dairy calves has also been suggested to help build social skills for later in life. It has been seen that those reared in grouped housing are more likely to become the dominant cattle in a new combination of animals. These dominant animals have a priority choice of feed or lying areas and are generally stronger animals. Due to these reasons, it has become common practice to group or pair calves in their housing. It has become common within Canada to see paired or grouped housing in outdoor hutches or within an indoor pack penning.

Bull

A bull calf with high genetic potential may be reared for breeding purposes. It may be kept by a dairy farm as a herd bull, to provide natural breeding for the herd of cows. A bull may service up to 50 or 60 cows during a breeding season. Anymore and the sperm count declines, leading to cows "returning to service" (to be bred again). A herd bull may only stay for one season, as when most bulls reach over two years old their temperament becomes too unpredictable. Bull calves intended for breeding commonly are bred on specialized dairy breeding farms, not production farms. These farms are the major source of stocks for artificial insemination.

FIGURE. 1.3. BULLS

Goat Farming

Goat farming is the raising and breeding of domestic goats (*Capra aegagrus hircus*). It is a branch of animal husbandry. Goats are raised principally for their meat, milk, fibre and skin. Goat farming can be very suited to production with other livestock such as sheep and cattle on low-quality grazing land. Goats efficiently convert sub-quality grazing matter that is less desirable for other livestock into quality lean meat. Furthermore, goats can be farmed with a relatively small area of pasture and limited resources

Meat

Three-quarters of the global population eat goat meat. It comprises 10% of worldwide meat consumption and 60% of red meat. Goat meat contains low amounts of saturated fatty acids and cholesterol. It is considered to be a healthier alternative to other types of red meat. The taste of goat kid meat has been reported as similar to that of spring

lamb meat. In some localities (e.g. the Caribbean, Bangladesh, Pakistan and India) the word "mutton" is used to describe both goat and lamb meat. However, some compare the taste of goat meat to veal or venison, depending on the age and condition of the goat.

The flavour is primarily linked to the presence of 4-methyloctanoic and 4-methylnonanoic acid. Goat meat can be prepared in a variety of ways, including stewing, baking, grilling, barbecuing, canning, and frying; it can be minced, curried, or made into sausage. Because of its low fat content, the meat can toughen at high temperatures if cooked without additional moisture. One of the most popular goats farmed for meat is the South African Boer, introduced into the United States in the early 1990s. The New Zealand Kiko is also considered a meat breed, as is the myotonic or "fainting goat"

Offal

When slaughtered, none of the animal need be wasted – so, all of the eviscerate can be used. This includes heart, liver, kidneys, spleen, lungs, stomach and intestines. The stomach can be eaten as tripe or stuffed like a haggis. The intestines make good sausage casings but have to be processed whilst still warm, otherwise the digestive enzymes start to digest the gut itself *post mortem*. Once cleaned out and cut into convenient lengths they can be turned inside out so that the internal lining can be scraped away with a knife. They can then be left in an isotopic cool solution (salty water) which keeps them supple until needed. This is traditionally done in autumn/fall when the temperature drops to below 55 degree Fahrenheit to avoid the meat within rotting -which can lead to botulism poisoning. Likewise, the skins need to be pricked so that air can ingress, as botulism needs an anaerobic medium in order to multiply. Goat sausages dry cured in this way, require no refrigeration. Modern curing methods include nitre to inhibit botulism but it is best not to wean a baby on sausages as it could induce *infantile botulism* from any spores present. It is considered by some that such dry cured sausages of goat, take on a rancid taste quite quickly and develop a *strong taste* so are not popular today. Yet, for those that like a goat taste it only adds to their appeal. In the case of billy goats, the testicles sliced and fried are considered a delicacy.

FIGURE. 1.4. GOAT

1.3.3 Milk, Butter and Cheese

Goats produce about 2% of the world's total annual milk supply. Some goats are bred specifically for milk. Unprocessed goat milk has small, well-emulsified fat globules, which means the cream remains suspended in the milk instead of rising to the top, as in unprocessed cow milk; therefore, it does not need to be homogenized. Indeed, if goat milk is to be used to make cheese, homogenization is not recommended, as this changes the structure of the milk, affecting the culture's ability to coagulate the milk and the final quality and yield of cheese. Dairy goats in their peak milk production (generally around the third or fourth lactation cycle) average 2.7 to 3.6 kg of milk production dairy roughly 2.8 to 3.8 l (3 to 4 U.S. qt) during a ten-month lactation, producing more just after freshening and gradually dropping in production toward the end of their lactation. The milk generally averages 3.5% butterfat.

Goat milk is commonly processed into cheese, butter, ice cream, yogurt, *cajeta* and other products. Goat cheese is known as *fromage de chèvre* ("goat cheese") in France. Some varieties include Rocamadour and Montrachet. Goat butter is white because goats produce milk with the yellow beta-carotene converted to a colourless form of vitamin A. Male goats are generally not required for the dairy-goat industry and are usually slaughtered for meat soon after birth. In the UK, approximately 30,000 billy goats from the dairy industry are slaughtered each year.

Fibre

Most goats have soft insulating hairs near the skin and longer guard hairs on the surface. The desirable fibre for the textile industry is the former; it has several names

including "down", "cashmere" and "pashmina". The guard hairs are of little value as they are too coarse, difficult to spin and difficult to dye. Goats are typically shorn twice a year, with an average yield of about 4.5 kg. In South Asia, cashmere is called "pashmina" (from Persian *pashmina*, "fine wool"). In the 18th and early 19th centuries, Kashmir (then called Cashmere by the British), had a thriving industry producing shawls from goat-hair imported from Tibet and Tartary through Ladakh. The shawls were introduced into Western Europe when the General in Chief of the French campaign in Egypt (1799–1802) sent one to Paris. Since these shawls were produced in the upper Kashmir and Ladakh region, the wool came to be known as "cashmere".

The Cashmere goat produces a commercial quantity of cashmere wool, which is one of the most expensive natural fibres commercially produced; cashmere is very fine and soft. The Cashmere goat fibre is harvested once a year, yielding around 260gm of down. Angora goats produce long, curling, lustrous locks of mohair. Their entire body is covered with mohair and there are no guard hairs. The locks constantly grow to 9 cm or more in length. Angora crossbreeds, such as the pygora and the nigora, have been selected to produce mohair and/or cashgora on a smaller, easier-to-manage animal.

The skin of goats is a valuable by product of goat farming. Up until 1849 all Rolls of Parliament were written upon parchment usually made from goat skin. Another populer use is for drum skins. Parchment is prepared by liming (in a solution of quick lime) to loosen the hair follicles.

CHAPTER 2

LITERATURE REVIEW

B.PRAVEEN KUMAR, S.RAJAGOPAL (2015) entitled as **"DAIRY AUTOMATION USING CONTROLLED AREA NETWORK PROTOCOL"** said, In these days automation in industry's increases rapidly. For safety purpose and to reduce man power requirement automation is adapted by industries. Some automation is fully automatic and some require human driver some control on automation. Automation has been achieved by various means including mechanical, hydraulic, pneumatic, electrical, electronic sensors, usually in combination. Complicated systems, such as, Milk Diaries, modern factories, airplanes and ships typically use all these combined techniques. These various sensor produced data collected by the vehicle data acquisition system by interactive communication through an intelligent information network called as Controlled area network.

It is a serial bus protocol to connect control system to sensors as an alternative to conventional multi- wire looms. They currently use PLC based system in Milk industries of southern India which is costly and a lot of noise is induced in the system as the distance between the control room and the area of work is large. And for the flushing of milk containers they use manually operated system which is quite time consuming and always increases the man power. This paper analyses an Architecture of control system and deals with its application using the controlled area network protocol. The benefits of this system over the system they currently employ is that noise reduction takes place as CAN is used and it is much cost effective than the PLC's and the man power is reduced. This prototype system hardware circuits mainly consist of LPC2129 32-bit Microcontroller, MCP 2551 CAN standalone Controller, MCP 2515 Transceiver. LPC 2129 32 -bit Microcontroller which based on ARM 7 Advanced RISC Architecture CPU serially interfaced with MCP 2515 and CAN Controller Rx and Tx pin connected to Tx and Rx pin of MPC 2551 transceiver.

From this literature we conclude that all the modern technologies are combined in the form of dairy system and also increase the milk production by using sensorized automotive controllers. Then analyse the farm area through CAN protocol.

AJINKYA S KADATE , ASHWINI R KANADE , ITI RASTOGI(2015) entitled as **"POLYHOUSE AUTOMATION USING PLC"** observed that, Poly-house is basically naturally ventilated climate controlled system. In poly-house various crops are grown under their favourable environmental conditions. Environmental conditions such as temperature within the poly-house, humidity of soil and atmosphere etc. Every crop needs different climatic conditions and to provide that condition farmers need manpower to do labour work. The system we designed and implemented on small working model of poly-house reduces labour and manpower. The various agricultural universities and agricultural experts provide the info about favourable condition and need of plant. Today we have cheap sensors and more precise and programmable controllers such as PLC available in the market. With the help of temperature, light intensity, humidity sensors and PLC automation of poly-house can be done. With the help of automation, minimum and effective use of valuable resources can lead to achieve maximum crop.

From this literature we conclude that the temperature, humidity and light intensity are kept as parameters for the automation of dairy farm and to reduce the work of labour in a cheap rate of materials.

NADER BARSOUM & ADRIAN PETER (2014) entitled as **"GSM GREENHOUSE MONITORING AND CONTROL OF TEMPERATURE AND SOIL MOISTURE"** observed that, Monitor and control of greenhouse environment play an important role in greenhouse production and management. To monitor the greenhouse environment parameters effectively and to match the crops needs is very challenging to a farmer as it needs 24hour of monitoring to the crops. Thus, it is necessary to design a control system to assist the farmer to boost up the production with reduction in human labour and assist in the greenhouse management. This paper presents basic monitoring and control method using mobile phone .GSM modem is used to control wirelessly the output variables of the greenhouse having the ability to monitor the parameters such as temperature and soil moisture in the greenhouse. This system is developed to bring convenience to the farmer to control and monitor the climate inside the greenhouse anywhere using SMS application.

Siemens TC35i Modem is used as SMS receiver while MCU PIC16F877A is connected to process the data by reading the content of the SMS. The MCU control the whole system and to enable the water pump and fan to operate by following the user

instruction through SMS. Moreover, the MCU can collect the climate data through the Temperature sensor and Soil moisture sensor and using TC35i modem to send it to the mobile phone whenever the farmer request for it. This paper describes the design of fully automated and manually greenhouse management system. From the experiment it is seen that the system is working properly which full fill the entire requirement related in greenhouse management. Thus, by using GSM technology the farmer can use mobile phone to control the fan and the water pump. The initial cost to implement this project may be costly but the cost can be cut when using low cost water pump and using low cost GSM modem which is the function is for messaging only.

From this literature we conclude that the process of monitoring and control of the dairy farm at regular intervals the monitoring process can also be done by mobile phones and monitoring the climate inside the green house using SMS from any location.

ROBERT J H DUNN, NAOMI E MEAD, KATE M WILLETT AND DAVID E PARKER (2014) entitled as ***"ANALYSIS OF HEAT STRESS IN UK DAIRY CATTLE AND IMPACT ON MILK YIELDS"*** said, Much as humans suffer from heat-stress during periods of high temperature and humidity, so do dairy cattle. Using a temperature-humidity index (THI), we investigate the effect of past heat waves in the UK on heat-stress in dairy herds. Daily THI data derived from routine meteorological observations show that during the summer, there has been an average of typically 1 day per year per station over the past 40 years when the THI has exceeded the threshold for the onset of mild heat-stress in dairy cattle. However, during the heat waves of 2003 and 2006, this threshold was exceeded on typically 5 days on average in the Midlands, south and east of England. Most dairy cattle are in the west and north of the country and so did not experience the severest heat. Milk yield data in the south-west of England show that a few herds experienced decreases in yields during 2003 and 2006. We used the 11-member regional climate model ensemble with the A1B scenario from UKCP09 to investigate the possible future change in days exceeding the THI threshold for the onset of mild heat-stress. The number of days where the THI exceeds this threshold could increase to over 20 day yr^{-1} in southern parts of England by the end of the century.

From this literature we conclude that the THI observation can be taken to determine the heat produced in the dairy farm and to maintain optimum temperature in the dairy farm.

CARIG THOMAS (2010) entitled as **"HEAT STRESS IN DAIRY CATTLE"** observed that, Thermal comfort for workers is very important factor to increase their performance, as well as the comfort level of dairy cattle will influence in milk productivity. The purposes of the paper is to measure the level of heat stress and then use the information to design the dairy cattle house for increasing thermal comfort. The research is started with literature review of heat stress and early survey of environment condition e.g. temperature, wind speed and relative humidity. The next step is using the information to determine the temperature humidity index (THI) level for dairy cattle with maximum THI = 86 and 84 (moderate stress). The 3D Computer Aided Designing model and Computational Fluid Dynamic simulation are employed to looking for solution for reducing the discomfort thermal of dairy cattle. A scenario (fan) air conditioning to get better condition of thermal comfort have been successfully presented with final THI index = 76 and 78 (mild stress). Finally, the paper shows how to reduce heat stress of cattle house by installation 3 exhaust fans in tropical climate.

From this literature we conclude that the heat stress in the cattle shed is determined and based on it the temperature is altered to the determined rate.

MRS.REENA P. SHINDE1 , MR.YOGESH (2010) entitled as **"AN SMART GREENHOUSE AUTOMATION SYSTEM APPLYING MOVING AVERAGE ALGORITHM"** observed that, Automation of greenhouses has proved to be extremely helpful in maximizing crop yields and minimizing labour costs. The optimum conditions for cultivating plants are regularly maintained by the use of programmed sensors and actuators with constant monitoring of the system. In this paper, we have designed a prototype of a smart greenhouse using Arduino microcontroller, simple yet improved in feedbacks and algorithms. Only three important microclimatic parameters namely moisture level, temperature and light are taken into consideration for the design of the system. Signals acquired from the sensors are first isolated and filtered to reduce noise before Arduino processes it. With the help of Lab view program, Time domain analysis and Fast Fourier Transform of the acquired signals are done to analyse the waveform.

Especially, for smoothing the outlying data digitally, Moving average algorithm is designed. With the implement of this algorithm, variations in the sensed data, which could occur from rapidly changing environment or imprecise sensors, could be largely smoothed and stable output could be created. In addition, actuators are controlled with constant feedbacks to ensure desired conditions are always met. Lastly, data is constantly acquired

by the use of Data Acquisition Hardware and can be viewed through Computer or Smart devices for monitoring purposes.

From this literature we conclude that the moving average algorithm is observed to sense the variations in the data due to rapidly changing environment or imprecise sensors.

G.ANDRÉ, B.ENGEL, P.B.M.BERENTSEN, TH.V.VELLINGA, AND A.G. J. M. OUDE LANSINK (2005) entitled as **"QUANTIFYING THE EFFECT OF HEAT STRESS ON DAILY MILK YIELD AND MONITORING DYNAMIC CHANGES USING AN ADAPTIVE DYNAMIC MODEL"** said, Automation and use of robots are increasingly being used within dairy farming and result in large amounts of real time data. This information provides a base for the new management concept of precision livestock farming. From 2003 to 2006, time series of herd mean daily milk yield were collected on 6 experimental research farms in the Netherlands. These time series were analysed with an adaptive dynamic model following a Bayesian method to quantify the effect of heat stress. The effect of heat stress was quantified in terms of critical temperature above which heat stress occurred, duration of heat stress periods, and resulting loss in milk yield. In addition, dynamic changes in level and trend were monitored, including the estimation of a weekly pattern. Monitoring comprised detection of potential outliers and other deteriorations.

The adaptive dynamic model fitted the data well; the root mean squared error of the forecasts ranged from 0.55 to 0.99 kg of milk/d. The percentages of potential outliers and signals for deteriorations ranged from 5.5 to 9.7%. The Bayesian procedure for time series analysis and monitoring provided a useful tool for process control. Online estimates (based on past and present only) and retrospective estimates (determined afterward from all data) of level and trend in daily milk yield showed an almost yearly cycle that was in agreement with the calving pattern: most cows calved in winter and early spring versus summer and autumn. Estimated weekly patterns in terms of weekday effects could be related to specific management actions, such as change of pasture during grazing. For the effect of heat stress, the mean estimated critical temperature above which heat stress was expected was 17.8 ± 0.56°C. The estimated duration of the heat stress periods was 5.5 ± 1.03 d, and the estimated loss was 31.4 ± 12.2 kg of milk/cow per year. Farm-specific estimates are helpful to identify management factors like grazing, housing and feeding,

that affect the impact of heat stress. The effect of heat stress can be decreased by modifying these factors.

The adaptive dynamic model is appropriate for quantification of the effect of heat stress for each farm in its specific situation in terms of critical temperature, duration, and effect on milk production. The critical temperature can be used as an indicator for the risk on heat stress based on daily weather forecasts. The duration can be used to evaluate and improve management regarding grazing, feeding, and housing during warm periods. The adaptive dynamic model is appropriate for evaluation and monitoring level and trend of herd mean daily milk yield, including the estimation of weekday effects. The online estimates provide useful information to the farmer to evaluate the actual situation and the retrospective estimates provide a good insight after- ward.

From this literature we conclude that the adaptive dynamic model is taken for quantification of the effect of heat stress in the dairy farm.

PERDIGONES, L. GARCIA , A. ROMERO , A. RODRIGUEZ , L. LUNA , C. RAPOSO , S. DE LA PLAZA(2004) entitled as **"COOLING STRATEGIES FOR GREENHOUSES IN SUMMER: CONTROL OF FOGGING BY PULSE WIDTH MODULATION"** observed that, The possibilities for improving the control of greenhouse fogging systems, were studied by comparing several combinations of ventilation cooling techniques, shade screening and low-pressure fogging. The study was divided into three parts: experiments, modelling and simulations. In the first part of the paper, ten combinations of five cooling techniques were tested during the summers of 2002 and 2003 in a 132-m^2 greenhouse with a steel structure and a single-layer methacrylate cover located in Madrid, Spain. An analysis of variance of the climatic parameters was carried out to determine which combinations produced significant differences in inside temperature or relative humidity. Comparing the values for the inside to outside temperature difference, the combination of a shade screen and above-screen fogging achieved a difference in temperature almost the same as that for under-screen fogging, but the relative humidity was significantly lower. In the second part of the study, a dynamic model was developed (2002) and validated (2003). The mean absolute error obtained for inside temperature was similar in the fit and the validation and it was less than 1.5 °C in both cases. The model was used to simulate the inside air temperature for a fog system working without shading, and above and under a shade screen. Control

algorithms were developed for reducing system water consumption. In the three cases a simple on/off control with a fixed fogging cycle was compared with a pulse width modulation (PWM) strategy, in which the duration of the fogging pulse was increased as a function of inside temperature.

The strategies with PWM applied to the fog system were able to reduce water consumption by 8-15% with respect to the strategies with a fixed fogging cycle. Combination of ventilation with shade screening and low-pressure fogging above the screen, but did not produce high humidity levels around the plant (mean relative humidity lower than 50%). It is therefore a suitable combination of equipment for crops that require cooling and relative humidity values far from saturation. A simple in situ calibration climate model has been used to evaluate the energy fluxes involved. This model can be easily used for control simulations. The absolute mean error for the calculation of the inside temperature was under 1.5 °C. The control of fogging using the PWM technique, regulating the fogging rate applied as a function of the inside temperature error yielded an estimated water saving of between 8% and 15% as compared with on/off control with fixed fogging cycles.

From this literature we conclude that the cooling strategies during summer and the method of fogging is been adopted to overcome the excess heat produced in the dairy farm.

J. W. WEST (2004) entitled as **"EFFECTS OF HEAT-STRESS ON PRODUCTION IN DAIRY CATTLE"** said, The south eastern United States is characterized as humid subtropical and is subject to extended periods of high ambient temperature and relative humidity. Because the primary non evaporative means of cooling for the cow (radiation, conduction, convection) become less effective with rising ambient temperature, the cow becomes increasingly reliant upon evaporative cooling in the form of sweating and panting. High relative humidity compromises evaporative cooling, so that under hot, humid conditions common to the Southeast in summer the dairy cow cannot dissipate sufficient body heat to prevent a rise in body temperature. Increasing air temperature, temperature-humidity index and rising rectal temperature above critical thresholds are related to decreased dry matter intake and milk yield and to reduced efficiency of milk yield.

Modifications including shade, barns which enhance passive ventilation, and the addition of fans and sprinklers increase body heat loss, lowering body temperature and improving DMI. New technologies including tunnel ventilation are being investigated to determine if they offer cooling advantages. Genetic selection for heat tolerance may be possible, but continued selection for greater performance in the absence of consideration of heat tolerance will result in greater susceptibility to heat stress. The nutritional needs of the cow change during heat stress, and ration reformulation to account for decreased dry matter intake, the need to increase nutrient density, changing nutrient requirements, avoiding nutrient excesses and maintenance of normal rumen function is necessary. Maintaining cow performance in hot, humid climatic conditions in the future will likely require improved cooling capability, continued advances in nutritional formulation, and the need for genetic advancement, which includes selection for heat tolerance or the identification of genetic traits which enhance heat tolerance. Extended periods of high ambient temperature coupled with high relative humidity compromise the ability of the lactating dairy cow to dissipate excess body heat. Cows with elevated body temperature exhibit lower DMI and milk yield and produce milk with lower efficiency, reducing profitability for dairy farms in hot, humid climates. Although adequate cooling systems exist their efficiency in humid climates is less than in arid climates and these systems often lack the ability to maintain normal body temperature.

From this literature we conclude that the effects of heat stress in the farm is reduced and the respective adaptive method is followed.

A.A.DIJKHUIZEN, M.A.TOMASZEWSKI (1996) entitled as **"ADAPTATION TO HOT CLIMATE AND STRATEGIES TO ALLEVIATE HEAT STRESS IN LIVESTOCK PRODUCTION"** observed that, Despite many challenges faced by animal producers, including environmental problems, diseases, economic pressure, and feed availability, it is still predicted that animal production in developing countries will continue to sustain the future growth of the world's meat production. In these areas, livestock performance is generally lower than those obtained in Western Europe and North America. Although many factors can be involved, climatic factors are among the first and crucial limiting factors of the development of animal production in warm regions. In addition, global warming will further accentuate heat stress-related problems. The objective of this paper was to review the effective strategies to alleviate heat stress in the

context of tropical livestock production systems. These strategies can be classified into three groups: those increasing feed intake or decreasing metabolic heat production, those enhancing heat-loss capacities, and those involving genetic selection for heat tolerance. Under heat stress, improved production should be possible through modifications of diet composition that either promotes a higher intake or compensates the low feed consumption. In addition, altering feeding management such as a change in feeding time and/or frequency, are efficient tools to avoid excessive heat load and improve survival rate, especially in poultry. Methods to enhance heat exchange between the environment and the animal and those changing the environment to prevent or limit heat stress can be used to improve performance under hot climatic conditions.

Although differences in thermal tolerance exist between livestock species (ruminants > monogastrics), there are also large differences between breeds of a species and within each breed. Consequently, the opportunity may exist to improve thermal tolerance of the animals using genetic tools. However, further research is required to quantify the genetic antagonism between adaptation and production traits to evaluate the potential selection response. With the development of molecular biotechnologies, new opportunities are available to characterize gene expression and identify key cellular responses to heat stress. These new tools will enable scientists to improve the accuracy and the efficiency of selection for heat tolerance. Epigenetic regulation of gene expression and thermal imprinting of the genome could also be an efficient method to improve thermal tolerance. Such techniques (e.g. perinatal heat acclimation) are currently being experimented in chicken.

From this literature we conclude that the tolerance of the cattle towards heat is determined and the optimum heat will provided to the cattle.

JEFFREY F. KEOWN AND RICHARD J. GRAN (1993) entitled as **"HEAT STRESS IN DAIRY CATTLE"** observed that, With an increase in herds than are housed or partially-house all-year-round there has been an increased awareness of the problems associated with heat stress in dairy cattle. High humidity and temperature levels in large buildings combined with poor air flow has been blamed for a 5-15% decrease in milk production and lowered conception rates, due to high cortisol (stress hormone) levels depressing intakes.As with any chronic forms of stress, cows can experience metabolic changes which can result in stress-related illnesses and depressed immunity. This can lead to a lowering of the cow's defences against

mastitis-causing pathogens. This, coupled with conditions in cattle housing that may favour the spread of bacteria can lead to an increase in clinical mastitis and raised Somatic Cell Counts.

The most visible symptoms of heat stress tend to be elevated breathing rates in a significant proportion of the herd. The first step in improving conditions for heat-stressed cows is to identify means of improving air flow and ventilation in buildings replacing doors with gates, or taking out alternate boards on spaced boarding are obvious suggestions. As a last resort, fans can be installed where other improvements cannot be made. Drinking water supply is another essential area in which conditions can be improved for heat-stressed cows; water intakes can increase by up to 10-20% in hot weather, particularly in high-yielders, which are more prone to suffering the effects of heat stress. Overcrowding should be avoided and cows allowed larger than normal space requirements by reducing stocking densities in buildings, if possible. It may also be wise to buffer feed cows either earlier in the morning or later in the evening when temperatures are lower. Rations should be balanced so that the ingredients most likely to degrade due to the heat are fed as efficiently as possible or replaced by other more suitable products. The mineral content of rations should also be reviewed so that the minerals lost in sweat in hot weather are replaced.

From this literature we conclude that the heat stress in the cattle is reduced by providing the optimum temperature for the cattle to survive the environmental conditions.

CHAPTER 3

METHODOLOGY

3.1 FLOWCHART

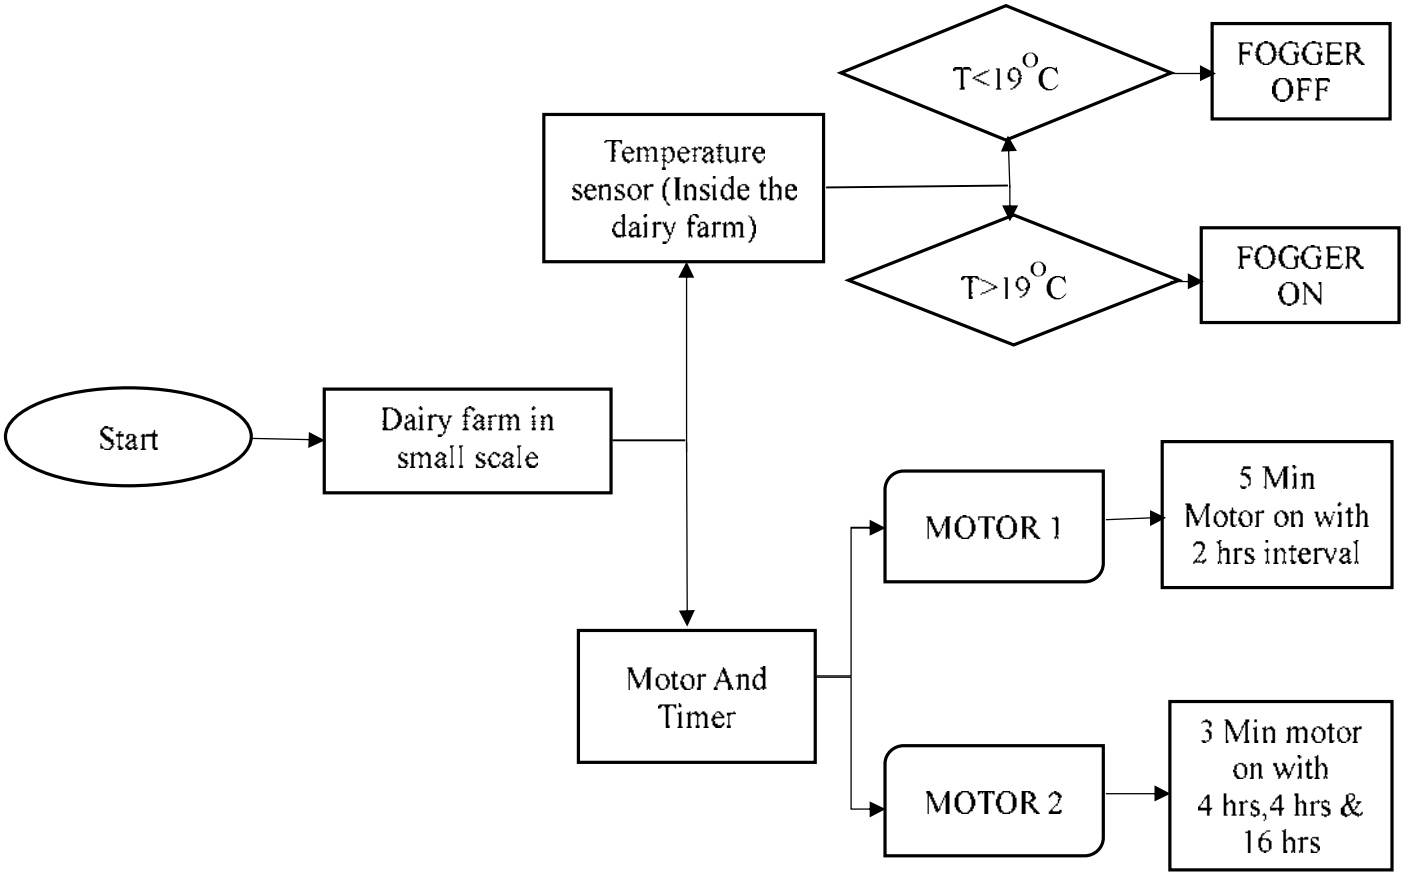

FIGURE. 3.1. FLOWCHART OF METHODOLOGY.

3.1.1 START: To give power of all components and check all components are worked well condition.

3.1.2 TEMPERATURE SENSOR: Temperature sensor is measured temperature range in outside greenhouse and signals are send to Arduino UNO.

3.1.3 T<19ºC: When a temperature range inside the shed are less than 19º C, the fogger is OFF.

3.1.4 T>19ºC: When a temperature range in inside the shed are greater than 19º C, the fogger is ON.

3.1.5 MOTOR (SUBMERSIBLE PUMP) : It was used for water feeding and cow dung was cleaned in between the duration by pressurized pump automatically with the help of Arduino IDE program

CHAPTER 4

MATERIALS AND ITS PROPERTIES

4.1. HARDWARE REQUIREMENT

- Arduino-UNO.
- Temperature sensor.
- Submerged pump.
- LCD display 16*2
- IC2 module
- Relay
- RTC Timer
- Fogger
- Piping system

SOFTWARE REQUIREMENT

- Arduino IDE.

HARDWARE ANALYSIS

4.1.1. ARDUINO - UNO

The Arduino UNO is an open-source microcontroller board based on the MicrochipATmega328P microcontroller and developed by Arduino. The board is equipped with sets of digital and analog input/output (I/O) pins that may be interfaced to various expansion boards (shields) and other circuits. The board has 14 Digital pins, 6 Analog pins, and programmable with the Arduino IDE (Integrated Development Environment) via a type B USB cable. It can be powered by the USB cable or by an external 9-voltbattery, though it accepts voltages between 7 and 20 volts. It is also similar to the Arduino Nano and Leonardo.

4.1.1.1 Properties of Arduino-UNO

- Microcontroller: Microchip AT mega328P.
- Operating Voltage: 5Volts.
- Input Voltage: 7 to 20Volts.
- Digital I/O Pins: 14 (of which 6 provide PWM output).
- Analog Input Pins: 6.
- DC Current per I/O Pin: 20mA.
- DC Current for 3.3V Pin: 50mA.
- Flash Memory: 32 KB of which 0.5 KB used by boot loader.
- SRAM: 2KB.
- EEPROM: 1KB.
- Clock Speed: 16MHz
- Length: 68.6mm
- Width: 53.4mm
- Weight: 25g

FIGURE. 4.1. ARDUINO UNO BOARD

4.1.2 TEMPERATURE SENSOR

The DS18B20 Stainless Steel Temperature Sensor is a pre-wired and waterproofed version of the DS18B20 sensor. Its unique 1-wire interface makes it easy to communicate with devices. It can converts temperature to a 12-bit digital word in 750ms(max). Besides, it can measures temperatures from -55°C to +125°C (-67F to +257F). In addition, this thermo probe doesn't require any external power supply since it draws power from data line. Its stainless steel probe head makes it suitable for any wet or harsh environment. The working principle of DS18B20 Stainless Steel Temperature Sensor and DS18B20 Temperature Sensor is same but the only difference is that the temperature sensor is placed inside the stainless steel probe.

4.1.2.1 Features

- Power supply range: 3.0V to 5.5V
- Operating temperature range:-55°C to +125°C (-67F to +257F)
- Temperature-limit alarm system
- ±0.5°C Accuracy from -10°C to +85°C
- 9 to 12 bit selectable resolution
- Uses 1-Wire interface- requires only one digital pin for communication

FIGURE. 4.2. TEMPERATURE SENSOR

4.1.3 SUBMERSIBLE PUMP

A submersible pump (or sub pump, electric submersible pump (ESP)) is a device which has a hermetically sealed motor close-coupled to the pump body. The whole assembly is submerged in the fluid to be pumped. The main advantage of this type of pump is that it prevents pump cavitation, a problem associated with a high elevation difference between pump and the fluid surfaces. Submersible pumps push fluid to the

surface as opposed to jet pumps which create a vacuum and rely upon atmospheric pressure. Submersibles are more efficient than jet pumps. Hydraulic submersible pumps (HSP's) use pressurised fluid from the surface to drive a hydraulic motor downhole, rather than an electric motor, and are used in heavy oil applications with heated water as the motive fluid.

4.1.3.1 Working principle

Electric submersible pumps are multistage centrifugal pumps operating in a vertical position. Liquids, accelerated by the impeller, lose their kinetic energy in the diffuser where a conversion of kinetic to pressure energy takes place. This is the main operational mechanism of radial and mixed flow pumps. In the HSP, the motor is a hydraulic motor rather than an electrical motor, and may be closed cycle (keeping the power fluid separate from the produced fluid) or open cycle (mingling the power fluid with produced fluid downhole, with surface separation). The pump shaft is connected to the gas separator or the protector by a mechanical coupling at the bottom of the pump. Fluids enter the pump through an intake screen and are lifted by the pump stages. There are also screw-type submersible pumps, there is a steel screw which is used as a working element in them. The screw allows the pump to work in water with a high sand content and other mechanical impurities.

FIGURE. 4.3. SUBMERSIBLE PUMP

4.1.4 LCD DISPLAY 16*2

The liquid-crystal display has the distinct advantage of having a low power consumption than the LED. It is typically of the order of microwatts for the display in comparison to the some order of milliwatts for LEDs. Low power consumption requirement has made it compatible with MOS integrated logic circuit. Its other advantages are its low cost, and good contrast. The main drawbacks of LCDs are additional requirement of light source, a limited temperature range of operation (between 0 and 60° C), low reliability, short operating life, poor visibility in low ambient lighting, slow speed and the need for an ac drive.

4.1.4.1 Structure of an LCD

A liquid crystal cell consists of a thin layer (about 10 u m) of a liquid crystal sandwiched between two glass sheets with transparent electrodes deposited on their inside faces. With both glass sheets transparent, the cell is known as transitive type cell. When one glass is transparent and the other has a reflective coating, the cell is called reflective type. The LCD does not produce any illumination of its own. It, in fact, depends entirely on illumination falling on it from an external source for its visual effect.

4.1.5 RELAY

The main usage of the Relay was seen in the history for transmitting and receiving the information, that was called as Morse code where the input signals used to be either 1 or 0, these change in signals were mechanically noted in terms of ON and OFF of a light bulb or a beep sound, it means those pulses of 1s and 0s are converted as mechanical ON and OFF using electromagnets. Later this was improvised and used in various applications. Let's see how this electromagnet acts as a switch and why it is named as RELAY.

4.1.5.1 Design of a Relay

An electromechanical relay is basically designed using few mechanical parts like Electromagnet, a movable armature, contacts, yoke, and a spring/frame/stand, these parts are showing in the internal pictures of Relay below. All these are arranged logically to form into a relay.

4.1.5.2 Construction of Relay and its operation:

Metal contact connected to another side, all these arrangements are placed over the core such that, when the coil is energized, it attracts the armature. The movable armature is generally considered as a common terminal which is to be connected to the external The following figure shows how a Relay looks internally and how it can be constructed,

4.1.5.3 Applications of Relay:

The applications of the relay are limitless, its main function is to control the high voltage circuit (230V circuit AC) with the low voltage power supply (a DC voltage).

- ❖ Relays are not only used in the large electrical circuits but also used in the computer circuits in order to perform the arithmetic and mathematical operations in it.
- ❖ Used to control the electric motor switches. To turn ON an electric motor we need 230V AC supply but in few cases/applications, there may be a situation to switch ON the motor with a DC supply voltage. In those cases, a relay can be used.
- ❖ Automatic stabilizers are one of its applications where a relay is used. When the supply voltage is other than the rated voltage, set of relays sense the voltage variations and controls the load circuit with the help of circuit breakers.
- ❖ Used for the circuit selection if there exists more than one circuit in a system.

4.1.6 FOGGER

The ELECTRO-GEN UNIT is a dual purpose chemical application device: A THERMAL FOGGER which produces a very small size droplet particle and an optional electric sprayer which produces a cold mist spray similar to that produced by an aerosol can.

4.1.6.1 Cold spraying mode

At the touch of the trigger, an electric pump draws solution from the solution reservoir. The solution is pressurized and forced through a specially restricted orifice where the solution is atomized into a cold mist. In the cold spraying mode the operator has a choice of utilizing water based or solvent based formulations, such as fabric protectors, deodor-ants, flame retardants, spotters, insecticides, etc. Special Advisory The use of resinous materials such as duct sealants, etc. may clog and damage the unit and are to be avoided.

4.1.6.2 Thermal fogging mode

At the touch of the trigger, an electric pump forces solution drawn from the solution reservoir through an atomizing nozzle and into a thermostatically controlled heating chamber in the barrel. The solution is vaporized instantly and a cloud of smoke like fog surges out of the end of the barrel. For odour removal applications always utilize ODORx® Thermo 55™. ODORx Application Advisory is Thermo 55 is ready-to-use and should not be diluted with water. For pest control applications be sure insecticide label permits

4.1.6.3 Thermal fogging.

For best results dry fog is recommended. The dryer the fog the smaller the droplets, resulting in improved penetration and economical treatment. Dryness of the fog is controlled by the rate of solution passing through the heating chamber. This flow rate is controlled by turning the adjustment knob clockwise for a dryer fog, and counter clockwise for a damper fog.

4.1.6.4 Specifications:

- MOTOR: Electro-Mechanical (vibrator)
- 7,200 strokes per minute
- Rating - refer to rating on plate
- PUMP: Displacement Type
- Output-Spraying: 1 ounce (30ml) per minute
- Fogging: 1,000 cubic feet (28 cubic meters) per minute

4.1.6.5 Particle Size

- Cold Spraying: 115 microns in diameter
- Fogging: 13.5 microns in diameter
- Heating element: Thermostatically Controlled
- Operating Temperature: 450° - 525°F (232°C - 274°C)
- Current: 115v = 8 amps Wattage: 900 Watts, 230v = 4 amps
- Solution reservoir: Spun Aluminium 3 quart (2.8 Litre) capacity

4.1.7 IC2 MODULE PROPERTIES

- Only 2 Arduino pins are occupied (Use I2C interface).
- Supports standard I2C mode (100Kbit/s) and fast I2C mode (400Kbit/s).
- Compatible with multiple communication logic levels: 2.8~5VDC.
- Arduino library supported, use a line of code to complete the display.
- Integrate 7 sizes of ASCll fonts, 5 graphics functions.
- Provide dedicated picture data convert software (Bitmap Converter).
- Most of the complex operation is processed by I2C_LCD independent controller, saving user controller resources.
- Supports cursor function, can set up 16 cursor flicker frequency.
- Supports 128 level backlight lightness adjustment.
- Support 64 level screen contrast adjustment.
- Support device address modification.
- Supports 127 I2C_LCD work in parallel.
- When debugging code, it can take the place of the serial monitor to monitor the program running state.
- Two abnormal recovery methods are provided: reset and restore the factory settings.
- Compatible with Grove interface and 4Pin-100mil interface (under the Grove socket).
- 4 symmetrical fixed hole design for easy user installation and China style unique appearance.

4.1.8 REAL TIME CLOCKS (RTC)

Real time clocks (RTC), as the name recommends are clock modules. The DS1307 real time clock (RTC) IC is an 8 pin device using an I2C interface. The DS1307 is a low-power clock/calendar with 56 bytes of battery backup SRAM. The clock/calendar provides seconds, minutes, hours, day, date, month and year qualified data. The end date of each month is automatically adjusted, especially for months with less than 31 days. They are available as integrated circuits (ICs) and supervise timing like a clock and also operate date like a calendar. The main advantage of RTC is that they have an arrangement of battery backup which keeps the clock/calendar running even if there is power failure.

An exceptionally little current is required for keeping the RTC animated. We can find these RTCs in many applications like embedded systems and computer mother boards, etc. In this article we are going to see about one of the real time clock (RTC), i.e. DS1307.

Pin Description of DS1307:

Pin 1, 2: Connections for standard 32.768 kHz quartz crystal. The internal oscillator circuitry is intended for operation with a crystal having a specified load capacitance of 12.5pF. X1 is the input to the oscillator and can alternatively be connected to an external 32.768 kHz oscillator. The output of the internal oscillator, X2 is drifted if an external oscillator is connected to X1.

Pin 3: Battery input for any standard 3V lithium cell or other energy source. Battery voltage should be between 2V and 3.5V for suitable operation. The nominal write protect trip point voltage at which access to the RTC and user RAM is denied is set by the internal circuitry as 1.25 x VBAT nominal. A lithium battery with 48mAhr or greater will backup the DS1307 for more than 10 years in the absence of power at 25ºC. UL recognized to ensure against reverse charging current when utilized as a part of conjunction with a lithium battery.

Pin 4: Ground.

Pin 5: Serial data input/output. The input/output for the I2C serial interface is the SDA, which is open drain and requires a pull up resistor, allowing a pull up voltage upto 5.5V. Regardless of the voltage on VCC.

Pin 6: Serial clock input. It is the I2C interface clock input and is used in data synchronization.

Pin 7: Square wave/output driver. When enabled, the SQWE bit set to 1, the SQW/OUT pin outputs one of four square-wave frequencies (1Hz, 4 kHz, 8 kHz, and 32 kHz). This is also open drain and requires an external pull-up resistor. It requires application of either Vcc or Vb at to operate SQW/OUT, with an allowable pull up voltage of 5.5V and can be left floating, if not used.

Pin 8: Primary power supply. When voltage is applied within normal limits, the device is fully accessible and data can be written and read. When a backup supply is connected to the device and VCC is below VTP, read and writes are inhibited. However at low voltages, the timekeeping function still functions.

4.1.8.1 Features:

- Programmable square wave output signal
- Automatic power-fail detect and switch circuitry
- Consumes less than 500nA in battery backup mode with oscillator running
- Available in 8-pin DIP or SOIC
- Underwriters Laboratory (UL) recognized
- Real-time clock (RTC) counts seconds, minutes, hours, date of the month, month, day of the week, and year with leap-year compensation valid up to 2100
- 56-byte non-volatile RAM for data storage
- Two-wire interface (I2C)

4.2 SOFTWARE ANALYSIS

4.2.1. Arduino IDE

The Arduino integrated development environment (IDE) is a cross-platform application (for Windows, Mac OS, Linux) that is written in the programming language Java. It is used to write and upload programs to Arduino compatible boards, but also, with the help of 3rd party cores, other vendor development boards. The source code for the IDE is released under the GNU General Public License, version 2.The Arduino IDE supports the languages C and C++ using special rules of code structuring. The Arduino IDE supplies a software library from the Wiring project, which provides many common input and output procedures. User-written code only requires two basic functions, for starting the sketch and the main program loop, that are compiled and linked with a program stub *main()* into an executable cyclic executive program with the GNU tool chain, also included with the IDE distribution. The Arduino IDE employs the program *avrdude*to convert the executable code into a text file in hexadecimal encoding that is loaded into the Arduino board by a loader program in the board's firmware.

4.2.1.1 Properties Of Arduinoide

- Arduino IDE is an open source software that is mainly used for writing and compiling the code into the Arduino Module.
- It is an official Arduino software, making code compilation too easy that even a common person with no prior technical knowledge can get their feet wet with the learning process.

- It is easily available for operating systems like MAC, Windows, Linux and runs on the Java Platform that comes with inbuilt functions and commands that play a vital role for debugging, editing and compiling the code in the environment.
- A range of Arduino modules available including Arduino Uno, Arduino Mega, Arduino Leonardo, Arduino Micro and many more.
- Each of them contains a microcontroller on the board that is actually programmed and accepts the information in the form of code.
- The main code, also known as a sketch, created on the IDE platform will ultimately generate a Hex File which is then transferred and uploaded in the controller on the board.
- The IDE environment mainly contains two basic parts: Editor and Compiler where former is used for writing the required code and later is used for compiling and uploading the code into the given Arduino Module.
- This environment supports both C and C++language.

CHAPTER 6

RESULT AND DISCUSSION

6.1 CIRCUIT CONNECTION

The circuit connections are given and testing images are given below,

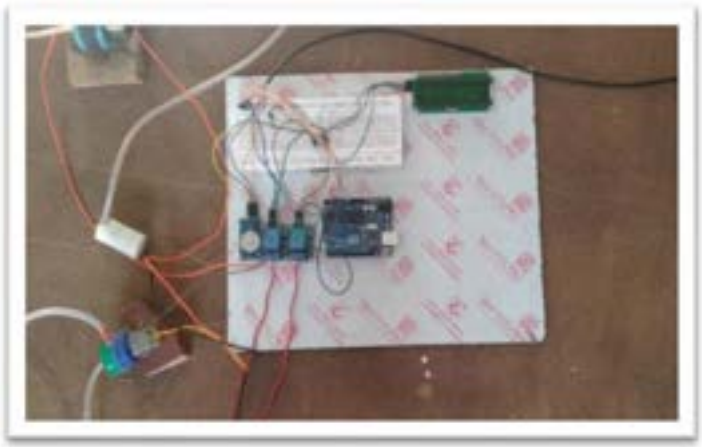

FIGURE. 6.1. ASSEMBLING OF COMPONENTS

FIGURE. 6.2. TESTING

6.2 WORKING PROCEDURE

While testing the output can be read in the Serial monitor of the Arduino. When the temperature level is above 85 degree Fahrenheit it will indicate as "Temperature level high", and if the temperature level is below 22° C degree then it will indicate as "Temperature level and cooling pump is off".

In the above the 22° C indicate the temperature level and cooling pump is on.

The output in the serial monitor is given below as images,

FIGURE. 6.3. DISPLAY IN SERIAL MONITOR

By program automatically water has pumped for some intervals to water feeder and cleaning the sheds at the perfect interval with the help of relay, it has been successfully checked.

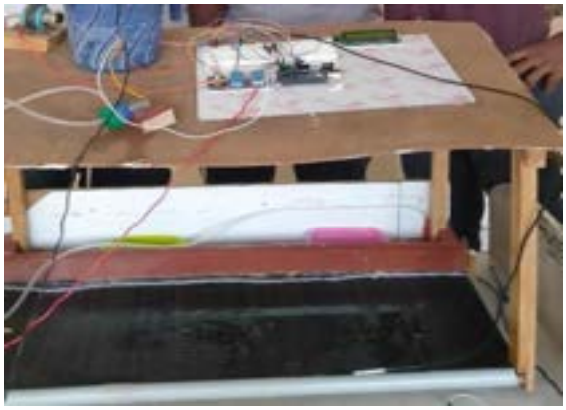

FIGURE. 6.4. WORKING MODEL

CHAPTER 7

CONCLUSION

We could that "AUTOMATION IN DAIRY FARM IN SMALL SCALE". Automation is useful for maintain the temperature or control the temperature in dairy farm.

From the result the fogger on automatically by using sensor. By using the automation it is possible to monitor the agriculture and its allied sector. The large number of farmer are now wanted a caution alert system. The combination of Arduino UNO and temperature senor can able to monitor the surrounding temperature. By implementing the automated monitoring system there is various benefits to the farmer. The cattle rearing is done every farm as for their additional income. Hence the Automation of dairy farm can also be key to maintain their income without decreasing. This also plays a big part in the integrated farm management. This automated system can be applicable for goat and sheep rearing and horse stable.

ABSTRACT

Sugarcane planting is a very labour intensive job and involves considerable human drudgery. Cost of sugarcane planting by mechanized method is less compared to traditional methods. It also reduces drudgery involved in unit operations of sugarcane planting. The reduction in cane yield owing to delayed planting cannot be compensated by additional inputs viz., frequent irrigations, extra fertilizers and inter culture operations. In order to achieve uniform crop stand, correct seed rate, appropriate depth of setts placements and uniformity of setts with required overlapping are important. These, however can better be achieved by using tractor-drawn sugarcane cutter planter apart from economizing labor and energy. Thus, recently developed sugarcane cutter planters are getting very good acceptance amongst sugarcane cultivators. Generally planting of any crop is very much important as far as the crop growth and yield is concern. This project describes regarding the design refinement of a sugarcane cutter planter and its prototype development. In this machine, the complete sugarcane, which is fed by the laborers sitting on the machine, is cut automatically into pieces before dropping into furrows. It also opens the furrows, applies fertilizer, chemical and fungicide and also covers the sets and presses it automatically. It is operated completely by a manual force.

Key words: *Human drudgery, Intercultural operations, Prototype.*

CHAPTER 1

INTRODUCTION

1.1 GENERAL

Sugarcane, an important agro-industrial crop in India, plays a vital role in national economy by contributing 1.9 per cent to GDP. The crop is cultivated in 4.22 m ha producing 300 tonnes with a productivity of 75-80 t/ha. However, there have been fluctuations in area as well as productivity over the years on account of several factors. Generally gur (Jaggery) and sugar are prepared from sugarcane. Sugarcane is propagated from cuttings, rather than from seeds. Although certain types still produce seeds, modern methods of stem cuttings have become the most common method of reproduction. Each cutting must contain at least one bud, and the cuttings are usually planted by hand. There are various methods of sugarcane planting like flat, trench, pit, staggered row and spaced transplanting. Hand harvesting accounts for more than half of the world's production, and is especially dominant in the developing world. Sugarcane planting requires about 350 men/hours and 30-40 bullock pairs per hour per hectare. Mechanization of sugarcane harvesting is an essential input to the modern agriculture, as it enhances better productivity, besides reducing human drudgery and cost of cultivation. Cost of sugarcane cultivation by mechanized process is almost one third of complete manual process.

Thus sugarcane planter cutters are getting great response from farmers, due to the reduction of drudgery involvement in unit operations, i.e. sett preparation, carrying of seed cane, opening of furrows, dropping of setts. But the majority of small scale industries in India, presently engaged in manufacture of agricultural implements are lacking design capability, for manufacturing its components, proper selection of materials and metallurgical treatments, proper tolerances for components and assembly methods to ensure quality durability and reliability. Moreover, these industries do not have R & D facilities and qualified manpower to produce quality products. Considering above points in mind, development of manually operated sugarcane chipping cum planting was undertaken based on the needs of farmers. The major sugarcane growing areas are Maharashtra, Tamilnadu and other few developed states of India. The planters manufactured in India are trailing type and PTO driven. Based on the survey conducted, it was decided to study the PTO driven

machines and make design refinement for quality manufacture of these machines. The tooling should be easily interchangeable to solve the problems of replacement of parts during breakdown. If tooling is standardized manufacture of components will be at reduced cost. During entire design refinement process following points was considered in detail:

- Uniform setts cutting and placement in the furrow.
- Manufacture of standardized components to ensure interchangeability of components.
- Desirable bund former design to obtain required depth for dropping sugarcane setts.

1.2 OBJECTIVE

The goal of this project is to design and fabricate a simple low cost sugarcane chipping cum planting machine which will greatly help the small scale farmers of India.

The main objectives of the project are:

1. To design and develop a low cost sugarcane chipping cum planting machine.
2. To reduce the labor cost.
3. To ensure timely planting of sugarcane setts.
4. To reduce human errors while planting setts.
5. To reduce human drudgery.

It will also lead to the reduction in production cost of sugarcane by reducing the labour cost and also it will minimize the losses that occur due to the delay in timely planting of sugarcane and manual errors while planting.

1.3 NEED OF THE PROJECT

The sugarcane cultivating farmers these days are greatly affected by the high production cost involved in the cultivation of sugarcane. The high cost involved in the cultivation is generally associated with high labour cost. In addition the yield of the sugarcane is also mainly affected due to the delay in timely planting of sugarcane setts and the error that is caused while planting the setts. So it becomes a major concern to eradicate all these problems. Which inspired us to innovate a machine which brings solution to all these problems.

1.4 PROBLEM IDENTIFICATION

Basically in villages we could able to see that most of the small scale farmers who cultivates sugarcane will start hiring labours for the planting works from one month prior to

the date of planting. He/She is also forced to pay large sum of money bargained by the labours for the work. This generally lead to high production cost of cultivation of sugarcane. In addition to this the farmers also suffer from low yield caused due to the delay in timely plantation of sugarcane setts and the manual error caused by the labours while planting the setts. These are all the major problems which we came across while observing and conversing with sugarcane cultivating farmers. This forced us to design and develop a machine which finds solution to all these problems for the welfare of sugarcane farmers and their productivity.

1.5 OUR WORK IN THE PROJECT

Our work in this project involves integrating all the knowledge gained in our course to find a solution to the problem by seeking ideas from various projects and experts and finally designing and developing an innovative machine which eradicates most of the problems faced by the sugarcane cultivating farmers of our country and to increase the overall sugarcane productivity of our nation.

1.6 EXPECTED OUTCOME

By implementing this project the cost of cultivating the sugarcane is greatly reduced. The losses that arise out of delayed plantation of sugarcane and germination that decreases due to improper placements of setts as a result of human error can be reduced. Overall implementing this machine in general reduces the market price of sugarcane and increases the overall sugarcane productivity.

CHAPTER 2

LITERATURE REVIEW

Dr.ManishKumar *et al* (2018) reported, "A BRIEF STUDY ON DIFFERENT TYPES OF SUGAR CANE PLANTERS IN INDIA" Sugarcane (*Saccharum officinarum L.*) is an important cash crop and cultivated between 320N to 320S latitude covering more than 90 countries of the world. Sugarcane contributes about 64.6%of the total world sugar production. India is one of the greatest producers of sugar and has a neck-to-neck race with Brazil for the first position. The sugar industry is an instrumental in generating the sizable employment in the rural sector directly and through its ancillary units.

It is estimated that about 50 million farmers and their dependents are engaged in the cultivation of sugarcane and about 0.5 million skilled and unskilled workers are engaged in sugar factories and its allied industries.Wheat-sugarcane-Raton cropping system is followed in whole of western Uttar Pradesh and lower parts of Uttrakhand where sugarcane is the main cash crop and wheat is the major cereal. The system accounts for more than 60% of the total cultivated area in the region. However, lower average yield of planted cane (50 tonnes/ha) recorded in this

In this paper we studied the performance of the different types of sugarcane cutter planters used in India. The main objective of this paper is to study the different. This project greatly helped us in gaining knowledge about different sugarcane planters available in India their working principles and their function which gave us a numerous no. of ideas in designing the project.

Subrata Kumar Mandal *et al* (2016) reported "DESIGN REFINEMENT OF 2 ROW TRACTOR MOUNTED SUGARCANE CUTTER PLANTER."Sugarcane planting is a very labour intensive job and involves considerable human drudgery. Cost of sugarcane planting by mechanized method is less compared to traditional methods. It also reduces drudgery involved in unit operations of sugarcane planting. Thus, recently developed sugarcane cutter planters are getting very good acceptance amongst sugarcane growers generally planting of any crop is very much important as far as the crop growth and yield is concern.

This paper describes regarding the design refinement of a sugarcane cutter planter and its prototype development. In this machine, the complete sugarcane, which is fed by the laborers

sitting on the machine, is cut automatically into pieces before dropping into furrows. It also opens the furrows, applies fertilizer, chemical and fungicide and also covers the sets and presses it automatically. It is operated by 35 hp tractor and has 2 units.. The set length was 31.8 cm with an average overlap of 6.48 cm observed at the speed of 2.5 km/hr. The seed rate capacity of machine was found 5.55 tons per ha.

This research had made us to use readymade fabricated parts so that easy replacements of the parts in any case of repair can be easily done. The implement also designed in such a type so that the traction between soil and the tool does not harm any parts of the implement due to the frictional force between the soil and the tool. This project gave us an innovative idea in various areas of designing the machine this also gave us a materialistic approach to deal with the project.

Vaibhav.V *et al* (2015) reported "DESIGN AND FABRICATION OF MULTIPURPOSE MACHINE FOR SUGARCANE PLANTING."India is a major producer of the sugarcane in the world and during 2009-10 it produced 18.9 million tons of sugar, which was nearly 11.8 % of the total sugar production of the world. So there is large space for development in sugarcane plantation. In conventional method of planting sugarcane sets are planted manually in furrows. This process is very much time consuming and labour intensive. So we developed the new machine which cuts the sugarcane and feeds into furrow as well as feeding of fertilizer and spraying pesticide is done automatically.

We use the cam operated mechanism with rotary cutter which cuts the sugarcane in uniform length and fed into the furrow due to gravitational force automatically. So piece of the sugarcane is distributed uniformly in the furrow so density of the sugarcane production is uniform. In traditional method fertilizer is spread by the hand so the density of feeding fertilizer is varies as per the worker which leads to extra supply of fertilizer.

This paper clearly explains the mechanism which feeds the fertilizer in uniform quantity. So after all processes leveler spreads the soil on pieces of sugarcane in the furrow. The main objective behind developing this machine is to fabricate a cost effective sugarcane planting machine which is suitable for Indian conditions where the land holding of the farmer is very small. This paper laid the foundation to our idea in combining both cutting and planting of sugarcane in a single machine. The principle of multipurpose design of this project gave us the innovative idea to combine all operations required for sugarcane plantation in our design.

A.K.Sharma *et al* (2013) reported "STUDY OF SUGARCANE PLANTING TECHNIQUES." The various layouts like flat bed planting, furrows at various spacing,

paired row planting and ring pit method of planting are being used in different parts of the world. Row spacing may range from 3 to 7 feet (91-213 cm). The choice of spacing depends on local conditions and varieties. This was also supported by many experiments at different locations at different period. Bhullar (2002) concluded that in India under late sown conditions, planting in furrows in paired rows (60 x 30 cm using 75,000 three budded setts-ha-1), was the most beneficial method of planting. Planting of sugarcane at row pacing of 75 and 90 cm being at par produced significantly higher cane and sugar yield. The buds of one budded placed upward gave 72.2% germination than the buds placed sideways (69.43%), and downward (23.61 %), (Fishier and Malik, 1992). The buds positioned downward always give poor germination and much delayed emergence of shoots. The researchers also tested the yield of the sugarcane by planting it with 1 to 6 eyes or bud in it. The observations of various yield was noted down respectively.

This project gave us a thorough knowledge about various sugarcane planting techniques and kind of techniques that is to be followed to obtain a maximized yield is clearly dealt with the project. The spacing specified here in this project was followed in the designed machine by attaching the bund former to the exact position so as to promote the machine with further advantage of enhancing good yield. And the machine also designed in such a way that the setts that are falling on the field falls in upward direction so that maximum yield up to 70% as mentioned in this paper can be obtained.

Prof. S.N.Waghmare *et al* (2011) reported "A REVIEW AND ANALYSIS ON MULTIPURPOSE FARM MACHINERIES." The objective is to design a project for small scale farmers. And in one machine multi functions can be performed with cheap cost as compared to other agriculture machine. So that it is not essential that a skilled person to operate it. Mechanism of the machine should be very simple for gardening and small scale farming. It consists of an internal framework that supports a man-made object in its construction and use. It is analogous to an animal's skeleton. An example of a chassis is the under part of a motor vehicle, consisting of the frame (on which the body is mounted). If the running gear such as wheels is included then the assembly is described as a rolling chassis. The chassis is considered to be one of the significant structures of an automobile. It is the frame which holds both the body of machine and the power train. Various mechanical parts like the engine and the drive train, the axle assemblies including the wheels, the suspension parts, the brakes, the steering components, etc., are bolted onto the chassis. Based on the overall performance of the machine we can definitely say that the project will satisfy the need of small scale farmer, because they are not able to purchase costly agricultural equipment.

The machine required less man power and less time compared to traditional methods, so if we manufacture it on a large scale its cost gets significantly reduce and we hope this will satisfy the partial thrust of Indian agriculture. So in this way we solve the labour problem that is the need of today's farming in India.

This machine gave us an idea to design a machine which is suitable for the small scale farmers of India as it reduces the cost of labour and greatly decreases the human drudgery and helps in timely operation. Further a particulate extension of this machine is made so as to fix sensors to make it fully automatic in future premises. This paper clearly dealt with the mechanism involved in designing multipurpose farm machineries. The various mechanisms behind combining the various activities on to a single platform were clearly explained in a simple and crispy manner along with various experimentations and observations. This paper also made us to think the possibilities of combining various equipments on to single parts and made them to work without any wear and tear.

R.K.Verma *et al* (2009) reported "**A STUDY ON FARM TOOLS AND EQUIPMENTS AND ITS DESIGN."** The study was conducted in the selected farm machine manufacturing companies in India. A total one hundred farm machine enterprises all over the India also taken into consideration (25 in each village) were randomly selected from the 22 states of India. Information related to indigenous tools used by them and other socio-personal traits were collected through interview schedule and focus group discussions. Most commonly used traditional agricultural tools and implements in various tribal dominating villages are illustrated in the study, which includes English or local name, description and their usages. A qualitative research approach was adopted for the study. In India, tribal farmers have been using a variety of traditional tools and implements for agricultural practices. The percentage distribution of traditional tools used by the tribal population of selected villages in Odisha and West Bengal.

This paper clears the fact that the *khurpa, sickle, daw*, *silnora, kula, jhuri* and *paniki* were found in every household. Spade was used by all households in Uttar Simlabari of West Bengal followed by 96, 72 and 56% household of Phatepur, Mobarakpur and Baredeswar of Odisha, respectively. It was observed that some of the tools like weed rack, hand stone mill, paddy spader, *bankua* and *khalui* were only found at Uttar Simlabari of West Bengal. From these observations we have found the types of tools that are available locally and ideas to perform little changes in the tools to make digger with digs the field with proper depth as per the optimum requirement of the sugarcane setts.

Punmia bhagat *et al* (2007) reported "**MOTION AND KINEMATICS OF FARM TOOLS AND EQUIPMENTS."** The development of guidance systems for agricultural vehicles receives more and more attention from researchers and manufacturers. The motivations are numerous; since automatic guidance reduces the work arduousness insures an optimal work precision throughout the day and on the whole field. For instance, it enables the exact placement of field inputs (seeds, fertilizers, pesticides) allows to operate wider tools at higher speeds, and therefore it can increase productivity. Many experiments have been conducted and reported in the literature. They can be classified into 2 categories, according to the kind of sensor to be used. The first category uses relative information. Researchers have focused for instance on the video camera sensor. Two kinds of difficulties arise: the first one is the reference extraction conditions of dust, for example, reveal the weakness of the detection side. The other problem arises when the new reference is computed in an iterative way from the previous one. The automatic guidance system can lead to oscillations. The tractor is assumed to move on a horizontal ground.

This paper enabled us in understanding the various kinematics involved in the operation of farm machineries. The curve linier motions and other complex kinematics which are involved in the functioning of the farm machineries are dealt clearly in this paper. The knowledge gained in this paper forms the base of the designing the conversion of rotary motion of the wheel into linier motion of the blade that involved in chipping operation. This paper also helped us in understanding the tractional force that involved between the machinery and soil and ways to reduce it for efficient operation.

Prof.Shivpratap *et al* (2005) reported "AN ANLYSIS ON TRACTOR OPERATED BUND FORMER AND ITS OPERATIONS."In mechanized farm, bund is prepared by a bund former either operated by tractor or animals for irrigation purposes and also to demarcate the fields. Tractor operated bund formers are normally either disc -or mould board or forming board type. If bund is formed with the help of traditional bund former, however, shaping and packing of bunds is done manually using spade and feet. To overcome the drudgery involve in these operations, a tractor operated bund former-cum-packer was designed and developed. An attempt is made for enabling the combined operations of bund forming and packing in single pass that can save fuel, time and other resources further.

CHAPTER 3

METHODOLOGY

3.1 METHODOLOGY FLOWCHART

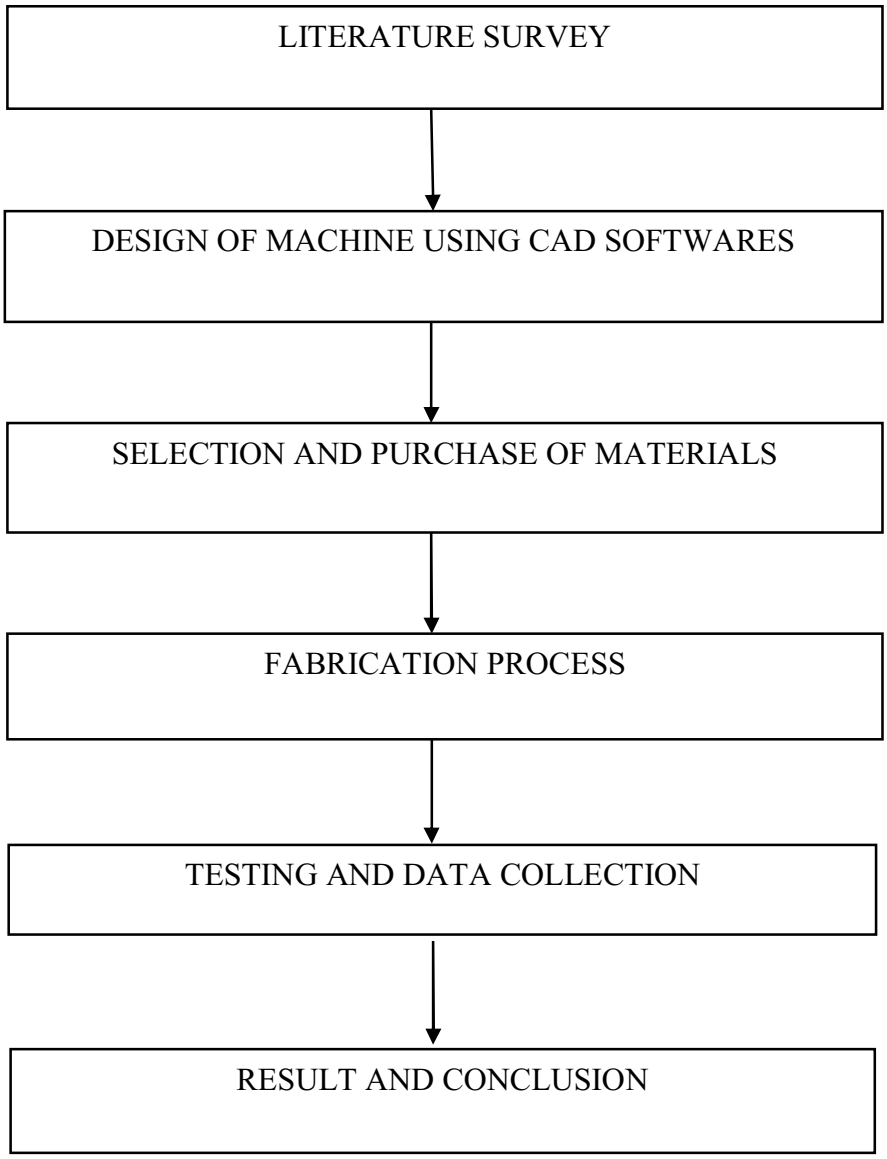

FIG 3.1 METHODOLOGY FLOWCHART

3.2 LITERATURE SURVEY

Literature review forms the base of any project. Various research journals, research papers, scientific journals of authors in India and around the world have been reviewed before starting the project. The major demand of the farmers and technical way of solving them was taken into account. The related projects which have been done earlier were keenly observed. The ideas of this project were taken from various research papers and previous projects which are then combined together to derive extraordinary solution for the problems faced.

3.3 DESIGN OF MACHINES USING CAD SOFTWARES

Engineering drawing is known as the language of engineers. The innovative idea which arises in the mind can be clearly explained only if that idea has been neatly sketched. Thus CAD software's help us a way of doing such drawings in an accurate and easy manner, hence forth the ideas was crafted into designs using this software. AUTOCAD 2020 and SOLID WORKS 2020 are the software's that are used in crafting this project. This forms the basis of designing any machine.

3.4 SELECTION AND PURCHASE OF MATERIALS

Selection of materials forms the basis of fabrication works. This also constitutes a major part in deciding the cost of the project. A clear idea has been made before purchasing of the raw materials. Things such as measurement of materials, properties of materials, cost of materials that is to be purchased should be planned and decided at the beginning stage of the project. Discussion with professors and local people will help us in sorting out the doubts which arises at this stage.

3.5 FABRICATION PROCESS

It is the main and complicated stage of any project, a special guidance from the project guide and other experts are required at this stage. Each and every step should be taken in cautious manner. The purchased raw materials were involved in many processes such as cutting, welding, drilling etc to be made into a desired project. Some change in the idea of design may occur at this stage of this due to the failure of preplanned process. This is the most time consuming stage and it must begin as soon as possible to get rid of delayed completion of work.

3.6 TESTING AND DATA COLLECTION

After the fabrication work was over it is the time for testing the machine on the field. The machine that is fabricated is supposed to be tested in the field to check its

efficiency. Testing is an important stage of the fabricated machine so that a conclusion can be made that whether that machine can be put into practical application or not. Further any problem that arises during the operation of the machine can be clearly noticed and necessary modification to overcome those problems can be taken.

3.7 RESULT AND CONCLUSION

This is the final stage of the project were the final result and efficiency of the machine should be specified. The information's such as no. of. Hectares that can be planted in an hour, the amount of human drudgery involved in operating the machine, maintenance required, name of the spare parts and their availability, safety measures that are to be followed while operating the machine etc are supposed to be specified in this area. This area determines that whether the project has the capability to put into practical applications or not is determined. The success of a project depends upon its final result.

4.2.1 SHEET METAL

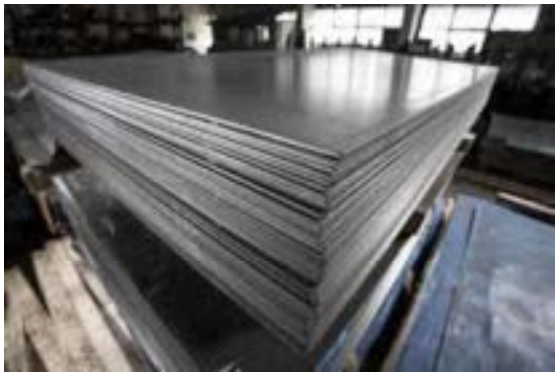

FIG 4.2 SHEET METAL

Sheet metal is metal formed by an industrial process into thin, flat pieces. It is one of the fundamental forms used in metalworking and it can be cut and bent into a variety of shapes. Countless everyday objects are fabricated from sheet metal. Thicknesses can vary significantly extremely thin thicknesses are considered foil or leaf, and pieces thicker than 6 mm (0.25 in) are considered plate. Sheet metal is available in flat pieces or coiled strips. The coils are formed by running a continuous sheet of metal through a roll slitter. There are many different metals that can be made into sheet metal, such as aluminum, brass, copper, steel, tin, nickel and titanium. For decorative uses, important sheet metals include silver, gold, and platinum (platinum sheet metal is also utilized as a catalyst.)

Sheet metal is used in automobile and truck (lorry) bodies, airplane fuselages and wings, medical tables, roofs for buildings (architecture) and many other applications. Sheet metal of iron and other materials with high magnetic permeability, also known as laminated steel cores, has applications in transformers and electric machines. Historically, an important use of sheet metal was in plate armor worn by cavalry, and sheet metal continues to have many decorative uses, including in horse tack. Sheet metal workers are also known as "tin bashers" (or "tin knockers"), a name derived from the hammering of panel seams when installing tin roofs

Sheet metal is used to make the table.

Thickness - 1mm

4.2.2 BLOWER

A centrifugal fan is a mechanical device for moving air or other gases in a direction at an angle to the incoming fluid. Centrifugal fans often contain a ducted housing to direct outgoing air in a specific direction or across a heat sink; such a fan is also called a blower fan, biscuit blower, or squirrel-cage fan (because it looks like a hamster wheel). These fans increase the speed and volume of an air stream with the rotating impellers. Centrifugal fans use the kinetic energy of the impellers to increase the volume of the air stream, which in turn moves against the resistance caused by ducts, dampers and other components.

FIG 4.3 BLOWER

Centrifugal fans displace air radically, changing the direction (typically by 90°) of the airflow. They are sturdy, quiet, reliable, and capable of operating over a wide range of conditions. Centrifugal fans are constant-displacement or constant-volume devices, meaning that, at a constant fan speed, a centrifugal fan moves a relatively constant volume of air rather than a constant mass. This means that the air velocity in a system is fixed even though the mass flow rate through the fan is not. Centrifugal fans are not positive-displacement devices and centrifugal fans have certain advantages and disadvantages when contrasted with positive-displacement blowers: centrifugal fans are more efficient, whereas positive-displacement blowers may have a lower capital cost. The centrifugal fan is one of the most widely used fans.

Centrifugal fans are by far the most prevalent type of fan used in the HVAC industry today. They are often cheaper than axial fans and simpler in construction. They are used in

transporting gas or materials and in ventilation systems for buildings and vehicles. They are also well-suited for industrial processes and air pollution control systems. The centrifugal fan has a drum shape composed of a number of fan blades mounted around a hub. As shown in the animated figure, the hub turns on a driveshaft mounted in bearings in the fan housing. The gas enters from the side of the fan wheel, turns 90 degrees and accelerates due to centrifugal force as it flows over the fan blades and exits the fan housing Backward-curved blades, curve against the direction of the fan wheel's rotation. Smaller blowers may have backward-inclined blades, which are straight, not curved. Larger backward-inclined curved blowers have blades whose backward curvatures mimic that of an airfoil cross section, but both designs provide good operating efficiency with relatively economical construction techniques.

These types of blowers are designed to handle gas streams with low to moderate particulate loadings. They can be easily fitted with wear protection but certain blade curvatures can be prone to solids build-up. Backward curved wheels are often heavier than corresponding forward-curved equivalents, as they run at higher speeds and require stronger construction. Backward curved fans can have a high range of specific speeds but are most often used for medium specific speed applications—high pressure, medium flow applications Backward-curved fans are much more energy efficient than radial blade fans and so, for high power applications may be a suitable alternative to the lower cost radial bladed fan.

4.2.3 CRANK SHAFT

A crankshaft related to crank is a mechanical part able to perform a conversion between reciprocating motion and rotational motion. In a reciprocating engine, it translates reciprocating motion of the piston into rotational motion whereas in a reciprocating compressor, it converts the rotational motion into reciprocating motion. In order to do the conversion between two motions, the crankshaft has "crank throws" or "crankpins", additional bearing surfaces whose axis is offset from that of the crank, to which the "big ends" of the connecting rods from each cylinder attach. It is typically connected to a flywheel to reduce the pulsation characteristic of the four-stroke cycle, and sometimes a torsional or vibrational damper at the opposite end, to reduce the torsional vibrations often caused along the length of the crankshaft by the cylinders farthest from the output end acting on the torsional elasticity of the metal.

`

FIG 4.4 CRANK SHAFT

A crankshaft for vessel engine is one of the most vital parts for ships. Crankshafts are roughly classified into two categories; built-up type crankshafts for 2-cycle diesel engines and solid type crankshafts for 4-cycle diesel engines. Built-up type crankshafts are made by shrink fitting journals to crank throws for the numbers of cylinders and are widely used for marine diesel engines with cylinder bore-diameters larger than approx. 400 mm. The two oil shocks forced low speed, two cycle, engine manufacturers to pursue lower energy consumptions and lower fuel costs. As a result, the engine strokes have become longer and the cylinder pressures have become higher. Also, the recent increasing size of ships has resulted in a requirement for higher powers and, at the same time, the needs to reserve maximum cargo space require downsizing of engines. The technical trend in the low-speed engine requires the built-up type crankshafts to have higher strength and higher reliability. Solid type crankshafts are press-formed from steel ingots and are used for mid- to high-speed, four cycles, engines with cylinder bore-diameters of less than 600 mm. Several developments are progressing for the 4 cycle engines to improve overall efficiencies. These include higher cylinder pressures, longer strokes and utilization of exhaust energy. As in the case of built-up type crankshafts, longer strokes and down-sizing are required for solid type crankshafts. An important requirement for solid type crankshafts is strength. Some of the engines employ materials with strength as high as 950 MPa. Along with the strengthening of materials, higher reliabilities are required more than ever for the crankshafts. This article describes the technical history of crankshaft materials and refers to notable trends in their technical developments.

4.2.4 SHAFT

Shaft is a common and important machine element. It is a rotating member, in general, has a circular cross-section and is used to transmit power. The shaft may be hollow or solid. The shaft is supported on bearings and it rotates a set of gears or pulleys for the purpose of power transmission. The shaft is generally acted upon by bending moment, torsion and axial force. Design of shaft primarily involves in determining stresses at critical point in the shaft that is arising due to aforementioned loading. Other two similar forms of a shaft are axle and spindle. Axle is a non-rotating member used for supporting rotating wheels etc. and do not transmit any torque. Spindle is simply defined as a short shaft.

FIG 4.5 SHAFT

However, design method remains the same for axle and spindle as that for a shaft. 8.1.2 Standard sizes of Shafts Typical sizes of solid shaft that are available in the market are, Up to 25 mm 0.5 mm increments 25 to 50 mm 1.0 mm increments 50 to 100 mm 2.0 mm increments 100 to 200 mm 5.0 mm increments 8.1.3 Material for Shafts The ferrous, non-ferrous materials and non metals are used as shaft material depending on the application. Some of the common ferrous materials used for shaft are discussed below. Hot-rolled plain carbon steel. These materials are least expensive. Since it is hot rolled, scaling is always present on the surface and machining is required to make the surface smooth. Since it is cold drawn it has got its inherent characteristics of smooth bright finish. Amount of machining therefore is minimal. Better yield strength is also obtained. This is widely used for general purpose transmission shaft

Specifications

Shaft diameter: 12mm

Material: mild steel

Length: 26 inch

Alloy steels

Alloy steel as one can understand is a mixture of various elements with the parent steel to improve certain physical properties. To retain the total advantage of alloying materials one requires heat treatment of the machine components after it has been manufactured. Nickel, chromium and vanadium are some of the common alloying materials. However, alloy steel is expensive. These materials are used for relatively severe service conditions. When the situation demands great strength then alloy steels are used. They have fewer tendencies to crack, warp or distort in heat treatment. Residual stresses are also less compared to CS (Carbon Steel). In certain cases the shaft needs to be wear resistant, and then more attention has to be paid to make the surface of the shaft to be wear resistant. The common types of surface hardening methods are,

- Hardening of surface
- Case hardening and carburizing
- Cyaniding and nit riding

4.2.5 WHEEL

A wheel is a ring-shaped vehicle component that covers the wheel's rim to protect it and enable better vehicle performance. Most tires, such as those for automobiles and bicycles, provide traction between the vehicle and the road while providing a flexible cushion that absorbs shock. The materials of modern pneumatic tires are synthetic rubber, natural, fabric and wire, along with carbon black and other chemical compounds. They consist of a tread and a body. The tread provides traction while the body provides containment for a quantity of compressed air. Before rubber was developed, the first versions of tires were simply bands of metal that fitted around wooden wheels to prevent wear and tear.

Early rubber tires were solid (not pneumatic).

FIG 4.6 WHEEL

Today, the majorities of tires are pneumatic inflatable structures, comprising a doughnut-shaped body of cords and wires encased in rubber and generally filled with compressed air to form an inflatable cushion. Pneumatic tires are used on many types of vehicles, including cars, bicycles, motorcycles, buses, trucks, heavy equipment, and aircraft. Metal tires are still used on locomotives and railcars, and solid rubber (or other polymer) tires are still used in various non-automotive applications, such as some casters, carts, lawnmowers, and wheelbarrows.

4.2.5.1 WHEEL HISTORY

Historically, the spelling was wheel and is of French origin, which comes from the word tire, to pull. The reason for this naming is that originally "tire" referred to iron hoops or thick wires bound to carriage wheels. In French blacksmithing the word for a drawn iron rod is a tire, or pull. The same word was often used for any metal drawing or rolling process. In an article in the London Magazine/Intelligencer of 1853 "The Utility of Broad Wheels," it explains that the common practice was to bend two rods, called "tires," into hoops and bind them to the wheel, but it is preferable to use an iron band, called a "broad wheel" rather than the rods, because as the rods wear they bite into the wheel. Another early mention of a tire in English is in The Scots Magazine, Volume 15 By James Boswell (1753). Another origin of "tire" is provided by Online Etymology Dictionary, essentially that the word is a short form of "attire," and that a wheel with a tire is a dressed wheel. Some other etymologists may share this view.

The earliest tires were bands of leather, then iron, (later steel), placed on wooden wheels, used on carts and wagons. The tire would be heated in a forge fire, placed over the wheel and quenched, causing the metal to contract and fit tightly on the wheel. A skilled worker, known as a wheelwright, carried out this work. The outer ring served to "tie" the wheel segments together for use, providing also a wear-resistant surface to the perimeter of the wheel. The word "tire" thus emerged as a variant spelling to refer to the metal bands used to tie wheels.

The first practical pneumatic tire was made in 1888 for his son Johnnie's tricycle, in May Street, Belfast by Scots-born John Boyd Dunlop, proprietor of one of Ireland's most prosperous veterinary practices. It was an effort to prevent the headaches his 10-year-old son was given by jarring while riding on rough pavements. His doctor, John, later Sir John Fagan, had prescribed cycling as an exercise for the boy and, a regular visitor, Fagan participated in the development of the first pneumatic schemes. In Dunlop's tire patent specification dated

31 October 1888 his interest is only in its use in cycles and light vehicles. In September 1890 he was made aware of an earlier development but the company kept the information to itself. In 1892 Dunlop's patent was declared invalid because of prior art by forgotten fellow Scot Robertson of London (patents London 1845, France 1846, USA 1847), although Dunlop is credited with "realizing rubber could withstand the wear and tear of being a tire while retaining its resilience J B Dunlop and Harvey du Cross together worked through the ensuing considerable difficulties. Because of its superiority in handling and fuel economy, use of this technology quickly spread throughout Europe and Asia. In the U.S., the outdated bias-ply tire construction persisted, with market share of 87% as late as 1967.Delay was caused by tire and automobile manufacturers in America concerned about transition costs. In 1968, Consumer Reports, an influential American magazine, acknowledged the superiority of radial construction, setting off a rapid decline in Michelin's competitor technology. Even in the U.S., the radial tire now has a market share of 100%.

4.2.5.2 WHEEL SUPPORT

There are two aspects to how pneumatic tires support the rim of the wheel on which they are mounted. First, tension in the cords pulls on the bead uniformly around the wheel, except where it is reduced above the contact patch. Second, the bead transfers that net force to the rim. Air pressure, via the ply cords, exerts tensile force on the entire bead surrounding the wheel rim on which the tire is mounted, pulling outward in a 360-degree pattern.

Thus the bead must have high tensile strength. With no force applied to the outer tread, the bead is pulled equally in all directions, thus no additional net force is applied to the tire bead and wheel rim. However, when the tread is pushed inward on one side, this releases some pressure on the corresponding sidewall ply pulling on the bead. Yet the sidewall ply on the other side continues to pull the bead in the opposite direction.

Thus the still fully tensioned sidewall ply pulls the tire bead and wheel rim in the direction opposite to the tread displacement and matching the total force applied to push the tread inward. This sidewall ply to bead tension support is a big reason for cross-ply cord tire construction. The cross-ply cord arrangement orients the cords to more directly support the sling. However, with improved combinations of cord and rim material construction materials and manufacturing techniques, combined with ongoing focus and research on tire efficiency and durability, it became feasible to manufacture radial-ply cord tires, which for many applications aiming for high speed without excessive loads, outperform similar cross-ply cord tire designs with reduced tire temperature, decreased rolling resistance and greater longevity.

4.2.5.3 WHEEL DESIGN

Pneumatic tires are manufactured in about 450 tire factories around the world. Over one billion tires are manufactured annually, making the tire industry major consumer of natural rubber. It is estimated that by 2015, 1.72 billion tires are expected to be sold globally. Tire production starts with bulk raw materials such as rubber, carbon black, and chemicals and produces numerous specialized components that are assembled and cured.

Many kinds of rubber are used, the most common being butadiene copolymer. This article describes the components assembled to make a tire, the various materials used, the manufacturing processes and machinery, and the overall business model. Butadiene copolymer is the most popular material used in the production of rubber tire.

In 2004, $80 billion of tires were sold worldwide; in 2010 it was $140 billion (approximately 34% growth adjusting for inflation). The top five tire manufacturing companies by revenue are Bridgestone, Michelin, Goodyear, Continental, and Pirelli.

4.2.5.4 MATERIALS:

The materials of modern pneumatic tires can be divided into two groups, the cords that make up the ply and the elastomeric which encases them.

4.2.5.5 CORDS

The cords, which form the ply and bead and provide the tensile strength necessary to contain the inflation pressure, can be composed of steel, natural fibers such as cotton or silk, or synthetic fibers such as nylon or Kevlar.

4.2.5.6 ELASTOMER

The elastomeric, which forms the tread and encases the cords to protect them from abrasion and hold them in place, is a key component of pneumatic tire design. It can be composed of various composites of rubber material – the most common being butadiene copolymer with other chemical compound such as silica and carbon black.

4.2.5.7 ROLLING RESISTANCE

Optimizing resistance in the elastomeric material is a key challenge for reducing fuel consumption in the transportation sector. It is estimated that passenger vehicles consume approximately 5~15% of its fuel to overcome rolling resistance, while the estimate is understood to be higher for heavy trucks. However, there is a trade-off between rolling resistance and wet traction and grip: while low rolling resistance can be achieved by reducing the viscoelastic properties of the rubber compound (low tangent (δ)), it comes at the cost of wet traction and grip, which requires hysteresis and energy dissipation (high tangent (δ)).

A low tangent (δ) value at 60 °C is used as an indicator of low rolling resistance, while a high tangent (δ) value at 0 °C is used as an indicator of high wet traction. Designing an elastomeric material that can achieve both high wet traction and low rolling resistance is key in achieving safety and fuel efficiency in the transportation sector.

The most common elastomeric material used today is a styrene-butadiene copolymer. It combines butadiene, which is a highly rubbery polymer (*Tg*= −100 °C) that has low hysteresis and thus offers good rolling resistance, with styrene, which is a highly glass polymer (*Tg*= 100 °C) that has high hysteresis and thus offers good wet grip properties in addition to wear resistance.

Therefore, the ratio the two polymers in the styrene-butadiene copolymer is considered key in determining the glass transition temperature of the material, which is correlated to its grip and resistance properties.

Materials science research efforts are underway to improve such properties of elastomers. For instance, this involves modifying the microstructure of the copolymer (for instance, using solution styrene butadiene rubber (SSBR) to control the addition of vinyl butadiene units)as well as the macrostructure of the polymer (such as the width of molecular weight distribution (MWD)).

Current investigation also involves looking at the fictionalization of the elastomer through the addition of filler materials such as silica and carbon black, as well as testing other nano-fillers such as nano cellulose crystals, carbon nano tubes, and grapheme.

4.2.5.8 COMPONENTS:

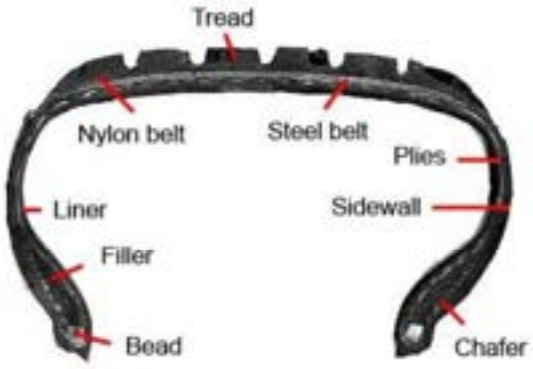

FIG 4.7 WHEEL CROSS SECTION

4.2.5.9 TREAD

The tread is the part of the tire that comes in contact with the road surface. The portion that is in contact with the road at a given instant in time is the contact patch. The tread is a thick rubber, or rubber/composite compound formulated to provide an appropriate level

of traction that does not wear away too quickly. The tread pattern is characterized by the geometrical shape of the grooves, lugs, sand ships. Grooves run circumferentially around the tire, and are needed to channel away water. Lugs are that portion of the tread design that contacts the road surface. Voids are spaces between lugs that allow the lugs to flex and evacuate water.

Tread patterns feature nonsymmetrical (or non-uniform) lug sizes circumferentially to minimize noise levels at discrete frequencies. Sipes are valleys cut across the tire, usually perpendicular to the grooves, which allow the water from the grooves to escape to the sides in an effort to prevent hydroplaning. Treads are often designed to meet specific product marketing positions. High performance tires have small void to provide more rubber in contact with the road for higher traction, but may be compounded with softer rubber that provides better traction, but wears quickly. Mud and snow (M&S) tires are designed with higher void ratios to channel away rain and mud, while providing better gripping performance.

The rain groove is a design element of the tread pattern specifically arranged to channel water away from the footprint. Rain grooves are circumferential in most truck tires. Many high performance passenger tires feature rain grooves that are angled from the center toward the sides of the tire. Some tire manufacturers claim that their tread pattern is designed to actively pump water out from under the tire by the action of the tread flexing. This results in a smoother ride in different types of weather. Sipe Tread lugs often feature small narrow voids, or sipes, that improve the flexibility of the lug to deform as it traverses the footprint area. This reduces shear stress in the lug and reduces heat buildup.

Testing of identical siped and unsiped tires showed measurable improvements in snow traction and ice braking performance, however diminishing and extending braking distances on wet and dry pavement by a few feet on siped tires. Off-road tire enthusiasts have been siping tires for years for greater traction, as many manufacturers now offer already siped off-road tires. Wear bar Wear bars (or wear indicators) are raised features located at the bottom of the tread grooves that indicate the tire has reached its wear limit.

When the tread lugs are worn to the point that the wear bars connect across the lugs, the tires are fully worn and should be taken out of service. Most wear bars indicate a remaining tread depth of 1.6 millimeters (0.063 in) and are deemed “worn out” at that point.

4.2.5.10 BEAD

Bead The bead is the part of the tire that contacts the rim on the wheel. The bead is typically reinforced with steel wire and compounded of high strength, low flexibility rubber. The bead seats tightly against the two rims on the wheel to ensure that a tubeless tire holds air without leakage. The bead fit is tight to ensure the tire does not shift circumferentially as the wheel rotates. The width of the rim in relationship to the tire is a factor in the handling characteristics of an automobile, because the rim supports the tire's profile

4.2.5.11 SIDEWALL

Sidewall Uneven sidewall wear, down to fabric plies, due to significant under-inflation the sidewall is that part of the tire that bridges between the tread and bead. The sidewall is largely rubber but reinforced with fabric or steel cords that provide for tensile strength and flexibility. The sidewall contains air pressure and transmits the torque applied by the drive axle to the tread to create traction but supports little of the weight of the vehicle, as is clear from the total collapse of the tire when punctured. Sidewalls are molded with manufacturer-specific detail government mandated warning labels, and other consumer information, and sometimes decorative ornamentation, likes whitewalls.

4.2.6 FRAME

The metal frame is generally made of mild steel bars for machining, suitable for lightly stressed components including studs, bolts, gears and shafts. It can be case-hardened to improve wear resistance. They are available in bright rounds, squares and flats, and hot rolled rounds Suitable machining allowances should therefore be added when ordering.

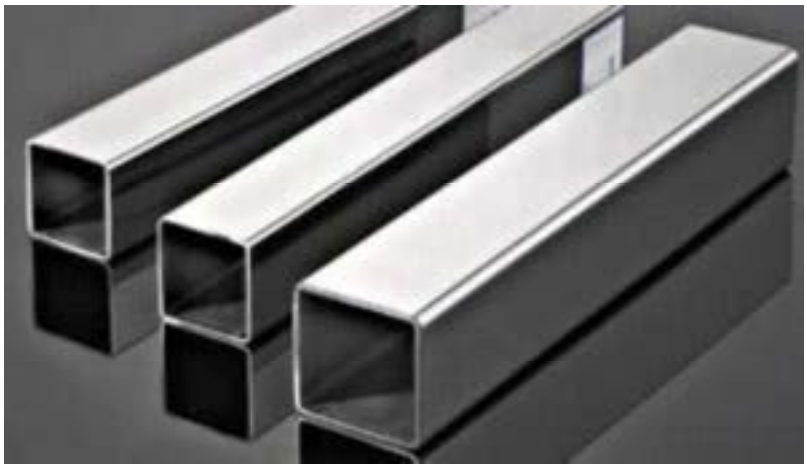

FIG 4.8 FRAME

It does not contain any additions for enhancing mechanical or machining properties. Bright drawn mild steel is an improved quality material, free of scale, and has been cold

worked (drawn or rolled) to size. It is produced to close dimensional tolerances. Straightness and flatness are better than black steel. It is more suitable for repetition precision machining. Bright drawn steel has more consistent hardness, and increased tensile strength. Bright steel can also be obtained in precision turned or ground form if desired.

Material - Mild steel

Size - 40*15cm

Thickness - 1mm

4.2.7 METAL STRIP

Metal strip or cold rolled strip is a steel product that is produced from a hot rolled strip that has been pickled. The coil is then reduced by a single stand cold roll steel mill straight away or reversing mill or in a tandem mill consisting of several single stands in a series. The strip is reduced to approximately final thickness by cold-rolling directly, or with the inclusion of an annealing operation at some intermediate thickness to facilitate further cold reduction or to obtain mechanical properties desired in the finished product.

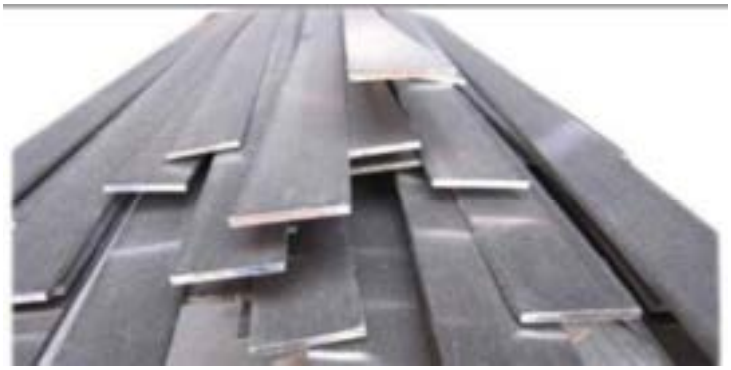

FIG 4.9 METAL STRIP

High carbon strip steel requires additional annealing and cold reduction operations. The coil is then slit to the desired width through the process of roll slitting. The final product typically consists of cold rolled steel that has been cut into strips of specific widths and coiled or oscillate coiled for delivery, frequently interleaved with paper or another material which protects the surface finish of the material and assists in retaining oil or some other rust prevention solution. This product is often later stamped to form a part from the strip steel.

4.2.8 BALL BEARING

A ball bearing is a type of rolling-element bearing that uses balls to maintain the separation between the bearing races. The purpose of a ball bearing is to reduce rotational friction and support radial and axial loads. It achieves this by using at least three races to contain the balls and transmit the loads through the balls. In most applications, one race is stationary and the other is attached to the rotating assembly (e.g., a hub or shaft).

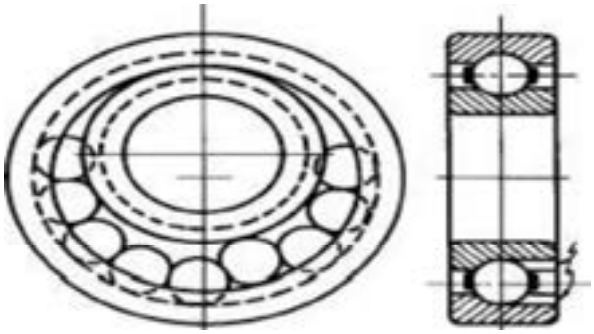

FIG 4.10 BALL BEARING

As one of the bearing races rotates it causes the balls to rotate as well. Because the balls are rolling they have a much lower coefficient of friction than if two flat surfaces were sliding against each other. Ball bearings tend to have lower load capacity for their size than other kinds of rolling-element bearings due to the smaller contact area between the balls and races. However, they can tolerate some misalignment of the inner and outer races.

Inner diameter: 12mm

Outer diameter: 37mm

Although bearings had been developed since ancient times, the first modern recorded patent on ball bearings was awarded to Philip Vaughan, a Welsh inventor and ironmaster who created the first design for a ball bearing in Carmarthen in 1794. His was the first modern ball-bearing design, with the ball running along a groove in the axle assembly. Jules Surrey, a Parisian bicycle mechanic, designed the first radial style ball bearing in 1869, which was then fitted to the winning bicycle ridden by James Moore in the world's first bicycle road race, Paris-Rouen, in November 1869.

4.2.8.1 DESIGN OF ANGULAR CONTACT

An angular contact ball bearing uses axially asymmetric races. An axial load passes in a straight line through the bearing, whereas a radial load takes an oblique path that acts to separate the races axially. So the angle of contact on the inner race is the same as that on the

outer race. Angular contact bearings better support combined loads (loading in both the radial and axial directions) and the contact angle of the bearing should be matched to the relative proportions of each. The larger the contact angle (typically in the range 10 to 45 degrees), the higher the axial load supported, but the lower the radial load. In high speed applications, such as turbines, jet engines, and dentistry equipment, the centrifugal forces generated by the balls changes the contact angle at the inner and outer race. Ceramics such as silicon nitride are now regularly used in such applications due to their low density (40% of steel). These materials significantly reduce centrifugal force and function well in high temperature environments. They also tend to wear in a similar way to bearing steel—rather than cracking or shattering like glass or porcelain. Most bicycles use angular-contact bearings in the headsets because the forces on these bearings are in both the radial and axial direction.

Axial

An axial or thrust ball bearing uses side-by-side races. An axial load is transmitted directly through the bearing, while a radial load is poorly supported and tends to separate the races, so that a larger radial load is likely to damage the bearing.

Deep-groove

In a deep-groove radial bearing, the race dimensions are close to the dimensions of the balls that run in it. Deep-groove bearings support higher loads than a shallower groove. Like angular contact bearings, deep-groove bearings support both radial and axial loads, but without a choice of contact angle to allow choice of relative proportion of these loads capacities.

Preloaded pairs

The above basic types of bearings are typically applied in a method of preloaded pairs, where two individual bearings are rigidly fastened along a rotating shaft to face each other. This improves the axial run out by taking up (preloading) the necessary slight clearance between the bearing balls and races. Pairing also provides an advantage of evenly distributing the loads, nearly doubling the total load capacity compared to a single bearing. Angular contact bearings are almost always used in opposing pairs: the asymmetric design of each bearing supports axial loads in only one direction, so an opposed pair is required if the application demands support both directions. The preloading force must be designed and assembled carefully, because it deducts from the axial force capacity of the bearings, and can

damage bearings if applied excessively. The pairing mechanism may simply face the bearings together directly, or separate them with a shim, bushing, or shaft feature.

Conrad

The Conrad-style ball bearing is named after its inventor, Robert Conrad, who was awarded British patent 12,206 in 1903 and U.S. patent 822,723 in 1906. These bearings are assembled by placing the inner ring into an eccentric position relative to the outer ring, with the two rings in contact at one point, resulting in a large gap opposite the point of contact. The balls are inserted through the gap and then evenly distributed around the bearing assembly, causing the rings to become concentric. Assembly is completed by fitting a cage to the balls to maintain their positions relative to each other. Without the cage, the balls would eventually drift out of position during operation, causing the bearing to fail. The cage carries no load and serves only to maintain ball position.

Conrad bearings have the advantage that they are able to withstand both radial and axial loads, but have the disadvantage of lower load capacity due to the limited number of balls that can be loaded into the bearing assembly. Probably the most familiar industrial ball bearing is the deep-groove Conrad style. The bearing is used in most of the mechanical industries.

Slot-fill

In a slot-fill radial bearing, the inner and outer races are notched on one face so that when the notches are aligned, balls can be slipped in the resulting slot to assemble the bearing. A slot-fill bearing has the advantage that more balls can be assembled (even allowing a full complement design), resulting in a higher radial load capacity than a Conrad bearing of the same dimensions and material type. However, a slot-fill bearing cannot carry a significant axial load, and the slots cause a discontinuity in the races that can have a small but adverse effect on strength.

Relieved race

Relieved race ball bearings are 'relieved' as the name suggests by basically have either the OD of the inner ring reduced on one side, or the ID of the outer ring increased on one side. This allows a greater number of balls to be assembled into either the inner or outer race, and then press fit over the relief. Sometimes the outer ring will be heated to facilitate assembly.

Like the slot-fill construction, relieved race construction allows a greater number of balls than Conrad construction, up to and including full complement and the extra ball count gives extra load capacity. However, a relieved race bearing can only support significant axial loads in one direction ('away from' the relieved race).

Fractured race

Another way of fitting more balls into a radial ball bearing is by radially 'fracturing' (slicing) one of the rings all the way through, loading the balls in, re-assembling the fractured portion, and then using a pair of steel bands to hold the fractured ring sections together in alignment. Again, this allows more balls, including full ball complement, however unlike with either slot fill or relieved race constructions, it can support significant axial loading in either direction.

Rows

There are two row designs: single-row bearings and double-row bearings. Most ball bearings are a single-row design, which means there is one row of bearing balls. This design works with radial and thrust loads. A double-row design has two rows of bearing balls. Their disadvantage is they need better alignment than single-row bearings.

Flanged

Bearings with a flange on the outer ring simplify axial location. The housing for such bearings can consist of a through-hole of uniform diameter, but the entry face of the housing (which may be either the outer or inner face) must be machined truly normal to the hole axis.

However such flanges are very expensive to manufacture. A more cost effective arrangement of the bearing outer ring, with similar benefits, is a snap ring groove at either or both ends of the outside diameter. The snap ring assumes the function of a flange.

Caged

Cages are typically used to secure the balls in a Conrad-style ball bearing. In other construction types they may decrease the number of balls depending on the specific cage shape, and thus reduce the load capacity. Without cages the tangential position is stabilized by sliding of two convex surfaces on each other. With a cage the tangential position is stabilized by a sliding of a convex surface in a matched concave surface, which avoids dents in the balls and has lower friction. Caged roller bearings were invented by John Harrison in the mid-18th century as part of his work on chronographs.

Hybrid ball bearings using ceramic balls

Ceramic bearing balls can weigh up to 40% less than steel ones, depending on size and material. This reduces centrifugal loading and skidding, so hybrid ceramic bearings can operate 20% to 40% faster than conventional bearings. This means that the outer race groove exerts less force inward against the ball as the bearing spins. This reduction in force reduces the friction and rolling resistance. The lighter balls allow the bearing to spin faster, and use less energy to maintain its speed. The ceramic balls are typically harder than the race. Due to wear, with time they will form a groove in the race. This is preferable to the balls wearing which would leave them with possible flat spots significantly harming performance. While ceramic hybrid bearings use ceramic balls in place of steel ones, they are constructed with steel inner and outer rings; hence the hybrid designation. While the ceramic material itself is stronger than steel, it is also stiffer, which results in increased stresses on the rings, and hence decreased load capacity. Ceramic balls are electrically insulating, which can prevent 'arcing' failures if current should be passed through the bearing. Ceramic balls can also be effective in environments where lubrication may not be available (such as in space applications). In some settings only a thin coating of ceramic is used over a metal ball bearing.

Fully ceramic bearings

These bearings make use of both ceramic balls and race. These bearings are impervious to corrosion and rarely require lubrication if at all. Due to the stiffness and hardness of the balls and race these bearings are noisy at high speeds. The stiffness of the ceramic makes these bearings brittle and liable to crack under load or impact. Because both ball and race are of similar hardness wear can lead to chipping at high speeds of both the balls and the race this can cause sparking.

Self-aligning

Self-aligning ball bearings, such as the Wingquist bearing shown in the picture, are constructed with the inner ring and ball assembly contained within an outer ring that has a spherical raceway. This construction allows the bearing to tolerate a small angular misalignment resulting from shaft or housing deflections or improper mounting. The bearing was used mainly in bearing arrangements with very long shafts, such as transmission shafts in textile factories. One drawback of the self-aligning ball bearings is a limited load rating, as the outer raceway has very low osculation (radius is much larger than ball radius). This led to the invention of the spherical roller bearing, which has a similar design, but use rollers

instead of balls. Also the spherical roller thrust bearing is an invention that derives from the findings by Linguist.

4.2.8.2 OPERATING CONDITION

Further information: Rolling-element bearing § Bearing failure the calculated life for a bearing is based on the load it carries and its operating speed. The industry standard usable bearing lifespan is inversely proportional to the bearing load cubed. Nominal maximum load of a bearing is for a lifespan of 1 million rotations, which at 50 Hz (i.e., 3000 RPM) a lifespan of 5.5 is working hours. 90% of bearings of that type have at least that lifespan, and 50% of bearings have a lifespan at least 5 times as long.

The industry standard life calculation is based upon the work of Lundberg and Palmgren performed in 1947. The formula assumes the life to be limited by metal fatigue and that the life distribution can be described by a Waybill distribution. Many variations of the formula exist that include factors for material properties, lubrication, and loading. Factoring for loading may be viewed as a tacit admission that modern materials demonstrate a different relationship between load and life than Lundberg and Palmgren determined.

4.2.8.3 FAILURE MODES

If a bearing is not rotating, maximum load is determined by force that causes plastic deformation of elements or raceways. The indentations caused by the elements can concentrate stresses and generate cracks at the components. Maximum load for not or very slowly rotating bearings is called "static" maximum load. Also if a bearing is not rotating, oscillating forces on the bearing can cause impact damage to the bearing race or the rolling elements, known as brinelling. A second lesser form called false brinelling occurs if the bearing only rotates across a short arc and pushes lubricant out away from the rolling elements. For a rotating bearing, the dynamic load capacity indicates the load to which the bearing endures 1,000,000 cycles. If a bearing is rotating, but experiences heavy load that lasts shorter than one revolution, static max load must be used in computations, since the bearing does not rotate during the maximum load.

If a sideways torque is applied to a deep groove radial bearing, an uneven force in the shape of an ellipse is applied on the outer ring by the rolling elements, concentrating in two regions on opposite sides of the outer ring. If the outer ring is not strong enough, or if it is not sufficiently braced by the supporting structure, the outer ring will deform into an oval shape from the sideways torque stress, until the gap is large enough for the rolling elements to

escape. The inner ring then pops out and the bearing structurally collapses. A sideways torque on a radial bearing also applies pressure to the cage that holds the rolling elements at equal distances, due to the rolling elements trying to all slides together at the location of highest sideways torque. If the cage collapses or breaks apart, the rolling elements group together, the inner ring loses support, and may pop out of the center.

Maximum load

In general, maximum load on a ball bearing is proportional to outer diameter of the bearing times the width of the bearing (where width is measured in direction of axle). Bearings have static load ratings. These are based on not exceeding a certain amount of plastic deformation in the raceway. These ratings may be exceeded by a large amount for certain applications. Increase in the load may be withstood up to the deformation level of bearing. Once if the plastic limit of the bearing is breached then it may cause deformation to the bearing.

Lubrication

For a bearing to operate properly, it needs to be lubricated. In most cases the lubricant is based on elasto hydrodynamic effect (by oil or grease) but working at extreme temperatures dry lubricated bearings are also available. For a bearing to have its nominal lifespan at its nominal maximum load, it must be lubricated with a lubricant (oil or grease) that has at least the minimum dynamic viscosity for a bearing where average of outer diameter of bearing and diameter of axle hole is 50 mm, and that is rotating at 3000 RPM, recommended dynamic viscosity is 12 mm^2/s. Note that dynamic viscosity of oil varies strongly with temperature a temperature increase of 50–70 °C causes the viscosity to decrease by factor 10.

If the viscosity of lubricant is higher than recommended, lifespan of bearing increases, roughly proportional to square root of viscosity. If the viscosity of the lubricant is lower than recommended, the lifespan of the bearing decreases and by how much depends on which type of oil being used. For oils with EP ('extreme pressure') additives, the lifespan is proportional to the square root of dynamic viscosity, just as it was for too high viscosity, while for ordinary oils lifespan is proportional to the square of the viscosity if a lower-than-recommended viscosity is used. Lubrication can be done with grease, which has advantages that grease is normally held within the bearing releasing the lubricant oil as it is compressed by the balls. It provides a protective barrier for the bearing metal from the environment, but

has disadvantages that this grease must be replaced periodically, and maximum load of bearing decreases (because if bearing gets too warm, grease melts and runs out of bearing). Time between grease replacements decreases very strongly with diameter of bearing for 40 mm bearing, grease should be replaced every 5000 working hours, while for a 100 mm bearing it should be replaced every 500 working hours. Lubrication can also be done with oil, which has advantage of higher maximum load, but needs some way to keep oil in bearing, as it normally tends to run out of it. For oil lubrication it is recommended that for applications where oil does not become warmer than 50 °C, oil should be replaced once a year, while for applications where oil does not become warmer than 100 °C, oil should be replaced 4 times per year. For car engines, oil becomes 100 °C but the engine has an oil filter to maintain oil quality; therefore, the oil is usually changed less frequently than the oil in bearings.

Direction of load

Most bearings are meant for supporting loads perpendicular to axle ("radial loads"). Whether they can also bear axial loads, and if so, how much, depends on the type of bearing. Thrust bearings (commonly found on lazy Susans) are specifically designed for axial loads. For single-row deep-groove ball bearings, SKF's documentation says that maximum axial load is circa 50% of maximum radial load, but it also says that "light" and/or "small" bearings can take axial loads that are 25% of maximum radial load. For single-row edge-contact ball bearings, axial load can be about 2 times max radial load, and for cone-bearings maximum axial load is between 1 and 2 times maximum radial load.

Often Conrad-style ball bearings will exhibit contact ellipse truncation under axial load. That means that either the ID of the outer ring is large enough, or the OD of the inner ring is small enough, so as to reduce the area of contact between the balls and raceway. When this is the case, it can significantly increase the stresses in the bearing, often invalidating general rules of thumb regarding relationships between radial and axial load capacity.

With construction types other than Conrad, one can further decrease the outer ring ID and increase the inner ring OD to guard against this. If both axial and radial loads are present, they can be added vectorially, to result in the total load on bearing, which in combination with nominal maximum load can be used to predict lifespan. However, in order to correctly predict the rating life of ball bearings the ISO/TS 16281 should be used with the help of calculation software.

Avoiding undesirable axial load

The part of a bearing that rotates (either axle hole or outer circumference) must be fixed, while for a part that does not rotate this is not necessary (so it can be allowed to slide). If a bearing is loaded axially, both sides must be fixed. If an axle has two bearings, and temperature varies, axle shrinks or expands, therefore it is not admissible for both bearings to be fixed on both their sides, since expansion of axle would exert axial forces that would destroy these bearings. Therefore, at least one of bearings must be able to slide.

A 'freely sliding fit' is one where there is at least a 4 μm clearance, presumably because surface-roughness of a surface made on a lathe is normally between 1.6 and 3.2 μm. If a shaft is supported by two bearings, and the center-lines of rotation of these bearings are not the same, then large forces are exerted on the bearing that may destroy it.

Fit

Bearings can withstand their maximum load only if the mating parts are properly sized. Bearing manufacturers supply tolerances for the fit of the shaft and the housing so that this can be achieved. The material and hardness may also be specified. Fittings that are not allowed to slip are made to diameters that prevent slipping and consequently the mating surfaces cannot be brought into position without force. For small bearings this is best done with a press because tapping with a hammer damages both bearing and shaft, while for large bearings the necessary forces are so great that there is no alternative to heating one part before fitting, so that thermal expansion allows a temporary sliding fit.

4.2.9 DISK

In geometry, a disk is the region in a plane bounded by a circle. A disk is said to be closed if it contains the circle that constitutes its boundary. The disk has circular symmetry. The open disk and the closed disk are not topologically equivalent (that is, they are not homeomorphic), as they have different topological properties from each other.

For instance, every closed disk is compact whereas every open disk is not compact. However from the viewpoint of algebraic topology they share many properties: both of them are contractible and so are hemitropic equivalent to a single point. This implies that their fundamental groups are trivial, and all homology groups are trivial except the 0^{th} one, which is isomorphic to Z.

FIG 4.11 DISK

The Euler characteristic of a point (and therefore also that of a closed or open disk) is 1. Every continuous map from the closed disk to itself has at least one fixed point; this is the case n=2 of the Brower fixed point theorem.

4.3 MANUFACTURING PROCESS

Manufacturing processes are the steps through which raw materials are transformed into a final product. The manufacturing process begins with the creation of the materials from which the design is made. These materials are then modified through manufacturing processes to become the required part. Manufacturing processes can include treating (such as heat treating or coating), machining, or reshaping the material. The manufacturing process also includes tests and checks for quality assurance during or after the manufacturing, and planning the production process prior to manufacturing.

4.3.1 SAWING:

Cold saws are saws that make use of a circular saw blade to cut through various types of metal, including sheet metal. The name of the saw has to do with the action that takes place during the cutting process, which manages to keep both the metal and the blade from becoming too hot. A cold saw is powered with electricity and is usually a stationary type of saw machine rather than a portable type of saw. The end result is that it is possible to complete a number of cutting projects before there is a need to replace the blade Steel blades of this type are resistant to wear even under daily usage. High speed steel blades are especially useful when the saws are used for cutting through thicker sections of metal.

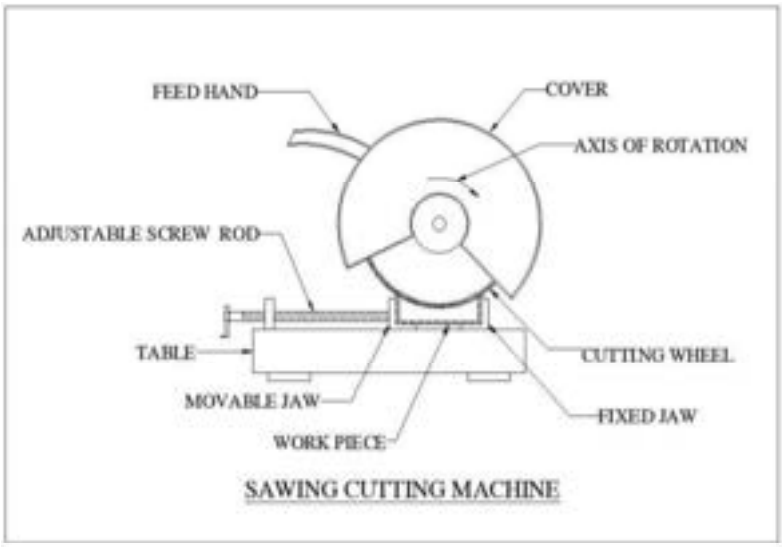

FIG 4.12 SAWING

4.3.2 WELDING:

Welding is a process for joining similar metals. Welding joins metals by melting and fusing 1, the base metals being joined and 2, the filler metal applied. Welding employs pinpointed, localized heat input. Most welding involves ferrous-based metals such as steel and stainless steel. Weld joints are usually stronger than or as strong as the base metals being joined. Welding is used for making permanent joints. It is used in the manufacture of automobile bodies, aircraft frames, railway wagons, machine frames, structural works, tanks, furniture, boilers, general repair work and ship building.

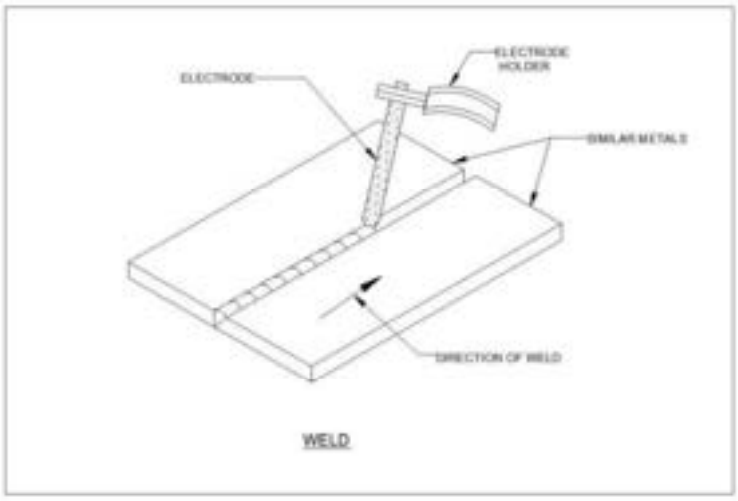

FIG 4.13 WELDING

Operation:

Several welding processes are based on heating with an electric arc, only a few are considered here, starting with the oldest, simple arc welding, also known as shielded metal arc welding (SMAW) or stick welding. In this process an electrical machine (which may be DC or AC, but nowadays is usually AC) supplies current to an electrode holder which carries an electrode which is normally coated with a mixture of chemicals or flux. An earth cable connects the work piece to the welding machine to provide a return path for the current. The weld is initiated by tapping ('striking') the tip of the electrode against the work piece which initiates an electric arc. The high temperature generated (about 6000^{o}C) almost instantly produces a molten pool and the end of the electrode continuously melts into this pool and forms the joint.

4.3.3 DRILLNG:

Drilling is a cutting process that uses a drill bit to cut or enlarge a hole of circular cross-section in solid materials. The drill bit is a rotary cutting tool, often multipoint. The bit is pressed against the work piece and rotated at rates from hundreds to thousands of revolutions per minute. This forces the cutting edge against the work piece, cutting off chips (sward) from the hole as it is drilled. Drilled holes are characterized by their sharp edge on the entrance side and the presence of burrs on the exit side (unless they have been removed).

Also, the inside of the hole usually has helical feed marks. Drilling may affect the mechanical properties of the work piece by creating low residual stresses around the hole opening and a very thin layer of highly stressed and disturbed material on the newly formed surface. This causes the work piece to become more susceptible to corrosion and crack propagation at the stressed surface. A finish operation may be done to avoid these detrimental conditions. For fluted drill bits, any chips are removed via the flutes.

Chips may form long spirals or small flakes, depending on the material, and process parameters. The type of chips formed can be an indicator of the machinability of the material, with long chips suggesting good material machinability. This minimizes the drill bit's tendency to walk that is, to be deflected from the intended center-line of the bore, causing the hole to be misplaced. The higher the length-to-diameter ratio of the drill bit, the greater the tendency to walk. The tendency to walk is also preempted in various other ways, which include:

4.3.3.1 Deep hole drilling

It is defined as drilling a hole of depth greater than ten times the diameter of the hole. These types of holes require special equipment to maintain the straightness and tolerances. Other considerations are roundness and surface finish. Deep hole drilling is generally achievable with a few tooling methods, usually gun drilling or BTA drilling.

These are differentiated due to the coolant entry method (internal or external) and chip removal method (internal or external). Using methods such as a rotating tool and counter-rotating work piece are common techniques to achieve required straightness tolerances.

Secondary tooling methods include trepanning, skiving and burnishing, pull boring, or bottle boring. Finally, a new kind of drilling technology is available to face this issue: vibration drilling. This technology breaks up the chips by a small controlled axial vibration of the drill.

The small chips are easily removed by the flutes of the drill. A high tech monitoring system is used to control force, torque, vibrations, and acoustic emission. Vibration is considered a major defect in deep hole drilling which can often cause the drill to break. A special coolant is usually used to aid in this type of drilling.

4.3.3.2 Gun drilling

Gun drilling was originally developed to drill out gun barrels and is used commonly for drilling smaller diameter deep holes. The depth-to-diameter ratio can be even greater than 300:1. The key feature of gun drilling is that the bits are self-centering; this is what allows for such deep accurate holes. The bits use a rotary motion similar to a twist drill; however, the bits are designed with bearing pads that slide along the surface of the hole keeping the drill bit on center. Gun drilling is usually done at high speeds and low feed rates.

4.3.3.3 Trepanning

Trepanning is commonly used for creating larger diameter holes (up to 915 mm (36.0 in)) where a standard drill bit is not feasible or economical. Trepanning removes the desired diameter by cutting out a solid disk similar to the workings of a drafting compass. Trepanning is performed on flat products such as sheet metal, granite (curling stone), plates, or structural members like I-beams. Trepanning can also be useful to make grooves for inserting seals, such as O-rings.

4.3.3.4 Micro drilling

Micro drilling refers to the drilling of holes less than 0.5 mm (0.020 in). Drilling of holes at this small diameter presents greater problems since coolant fed drills cannot be used and high spindle speeds are required. High spindle speeds that exceed 10,000 RPM also require the use of balanced tool holders.

4.3.3.5 Vibration drilling

Vibration drilling of an aluminum-CFRP multi-material stack with MITIS technology. The first studies into vibration drilling began in the 1950s (Pr. V.N. Poduraev, Moscow Bauman University). The main principle consists in generating axial vibrations or oscillations in addition to the feed movement of the drill so that the chips break up and are then easily removed from the cutting zone.

There are two main technologies of vibration drilling: self-maintained vibration systems and forced vibration systems. Most vibration drilling technologies are still at a research stage. In the case of self-maintained vibration drilling, the Eigen frequency of the tool is used in order to make it naturally vibrate while cutting; vibrations are self-maintained by a mass-spring system included in the tool holder.

Other works use a piezoelectric system to generate and control the vibrations. These systems allow high vibration frequencies (up to 2 kHz) for small magnitude (about a few micrometers); they are particularly suitable for drilling small holes.

Finally, vibrations can be generated by mechanical systems the frequency is given by the combination of the rotation speed and the number of oscillation per rotation (a few oscillations per rotation), with magnitude about 0.1 mm.

This last technology is a fully industrial one (example: Sine Holing technology of MITIS). Vibration drilling is a preferred solution in situations like deep hole drilling, multi-material stack drilling (aeronautics) and dry drilling (without lubrication). Generally, it provides improved reliability and greater control of the drilling operation.

The main principle consists in generating axial vibrations or oscillations in addition to the feed movement of the drill so that the chips break up and are then easily removed from the cutting zone.

4.4 CALCULATIONS

4.4.1 DESIGN OF SHAFT

For the design of shaft following two methods are adopted, Design based on Strength In this method, design is carried out so that stress at any location of the shaft should not exceed the material yield stress.

However, no consideration for shaft deflection and shaft twist is included. Design based on Stiffness Basic idea of design in such case depends on the allowable deflection and twist of the shaft.

4.4.1.1 DESIGN BASED ON STRENGTH

The stress at any point on the shaft depends on the nature of load acting on it. The stresses which may be present are as follows.

Basic stress equations:

Bending stress

$$\sigma_b = \frac{32M}{\pi d_0^3 (1 - k^4)}$$

Where,

M: Bending moment at the point of interest

do: Outer diameter of the shaft

k: Ratio of inner to outer diameters of the shaft (k = 0 for a solid shaft because inner diameter is zero)

Axial Stress

$$\sigma_a = \frac{4\alpha F}{\pi d_0^2 (1 - k^2)}$$

Where,

F: Axial force (tensile or compressive)

α: Column-action factor(= 1.0 for tensile load)

The term α has been introduced in the equation. This is known as column action factor. What is a column action factor? This arises due the phenomenon of buckling of long slender members which are acted upon by axial compressive loads.

Here, α is defined as,

$$\alpha = \frac{1}{1-0.0044(L/K)} \quad \text{for } L/K < 115$$

$$\alpha = \frac{\sigma_{yc}}{\pi^2 nE}\left(\frac{L}{K}\right)^2 \qquad \text{for } L/K > 115$$

Where,

n = 1.0 for hinged end

n = 2.25 for fixed end

n = 1.6 for ends partly restrained, as in bearing

K = least radius of gyration,

L = shaft length

Σyc= yield stress in compression

Stress due to torsion

$$\tau_{xy} = \frac{16T}{\pi d_0^3(1-k^4)}$$

Where,

T: Torque on the shaft

xy τ: Shear stress due to torsion

Combined Bending and Axial stress

Both bending and axial stresses are normal stresses; hence the net normal stress is given by,

$$\sigma_x = [\frac{32M}{\pi d_0^3(1-k^4)} \pm \frac{4\alpha F}{\pi d_0^2(1-k^2)}]$$

The net normal stress can be either positive or negative. Normally, shear stress due to torsion is only considered in a shaft and shear stress due to load on the shaft is neglected.

Maximum shear stress theory

Design of the shaft mostly uses maximum shear stress theory. It states that a machine member fails when the maximum shear stress at a point exceeds the maximum allowable shear stress for the shaft material. Therefore,

$$\tau_{max} = \tau_{allowable} = \sqrt{\left(\frac{\sigma_x}{2}\right)^2 + \tau_{xy}^2}$$

Substituting the values of σx and τxy in the above equation, the final form is,

$$\tau_{allowable} = \frac{16}{\pi d_0^3 (1-k^4)} \sqrt{\left\{ M + \frac{\alpha F d_0 (1+k^2)}{8} \right\}^2 + T^2}$$

Therefore, the shaft diameter can be calculated in terms of external loads and material properties. However, the above equation is further standardized for steel shafting in terms of allowable design stress and load factors in ASME design code for shaft.

4.4.1.2 SPECIFICATIONS

Material: Mild steel

Outer diameter: 250mm

Thickness: 5mm

Consider for example the function

$$f(x,y) = \left(\frac{x + \sqrt{1-y^2}}{2}, y \right)$$

Which maps every point of the open unit disk to another point on the open unit disk to the right of the given one? But for the closed unit disk it fixes every point on the half circle.

4.4.2 DESIGN OF CIRCULAR DISC

4.4.2.1 TORQUE CALCULATION ON A CIRCULAR DISC

- Diameter(d)=300 mm
- Thick(t)= 5 mm
- RPM(N)=100
- Let, Y.S. of mild steel(Y)=250 N/mm^2
- Now ,Allowable Shear Stress(S)=Y*0.5 =250*0.5 =125 N/mm^2
- Let, F.O.S.(F)=2.5
- Therefore, Allowable Shear Stress=S/F =125/2.5 = 50 N/mm^2

Also, Let Polar moment of Inertia is "J" and the Radius of shaft "R"(also the maximum distance from center)

Now, the formula for torque is,

Torque(T)= (J*S)/R

Now, J = (3.14*d^4)/32

= (3.14*300^4)/32

= 794812500 mm^4

Now, substitute all the values,

T = (794812500*50)/150

= 264937500 N-mm

T = 265 KN-M

Now, The formula for power required,

Power(P) = T*W

where, W= angular velocity

Now, W= (2*3.14*N)/60

= (2*3.14*100)/60

= 10.5 RPS

now substitute the values,

P = (265*10.5)

= 2774 KN-m/s

P = 2774 KW

4.5 WORKING PRINCIPLE

The equipment is placed where cane cultivation has to be done and the setup is moved manually by placing plugging rod into the soil surface, this tends to dig the hole for planting the cane. On the other hand the obtained rotation of wheel is converted into linear motion with the help of slider crank mechanism connected between axle shaft and blade. The obtained linear motion makes the blade to slide linear towards top and bottom and causes the loaded full cane to cut in to piece, when the blade moves towards top for next cutting stroke the loaded cane is feed into the cutting space automatically through gravitational force. The cane pieces are unloaded manually and planted inside the furrow.

4.6 STEPS INVOLVED IN FABRICATION PROCESS

1. Collecting the required raw materials.
2. Cutting the metal bars to required sizes.
3. Fabrication of frame as per the design with the help of the metallic bars by welding process.

4. Designing the wheel with the help of circular disc and metal strips by welding process
5. Ordering the blade as per the requirement.
6. Connecting the blade to the wheel with the help of crank shaft to convert rotary motion of wheel into linear motion of blade.
7. Designing the bund former with the help of metal plates and metallic bars.
8. Attaching the handle to push the machine with the help of metal bars.

4.7 CONSTRUCTION

The base frame which acts a bed of machine is fabricated with the help of square tubes and channels by metal cutting and metal joining process called welding. Two wheels are attached at the back end portion of frame with the help of axle shaft; the axle shaft is connected with base frame through bearing support in order to attain free rotation. At both the ends of axle shaft near the wheels crank rod is connected, this crank rod is coupled to the blade with the help of coupler rod. The blade is supported by the guide way for attaining proper linear motion. The feeding link is provided near the blade which holds and feeds the cane into the blade through gravitational force. At the front end portion of frame two plugging rods are placed to performing sand digging operation.

CHAPTER 5

RESULT AND DISCUSSION

5.1 ASSESMENT OF SEED RATE

Let us calculate the seed rate of the machine by assuming the land to be planted was one hectare with machine moving at the speed of 1km/hr with depth of furrow made by the bund former is about 12.5cm and the turning loss is around 10%.

We know that the space between the furrow openers = 60.9cm

We also know that the width of the machine = 60.9cm

Theoretical area/hr $= \frac{60.9}{100} \times \frac{1 \times 1000}{10000} = 0.06$ ha

Actual area/hr $= \frac{0.06 \times 90}{100} = 0.05$ ha

Time for sowing one hectare $= \frac{1}{0.05} = 20$ hrs.

Thus it has been found that maximum of 20 hrs is required to plant an area of 20 hectares.

5.2 ASSESMENT OF EFFICIENCY

This machine was put to use under variable soil conditions after ploughing and its efficiency in different soil conditions were noted down.

Dry soil

Loamy soil is generally rich in organic matter, humus and other nutrient content. Sugarcane is generally cultivated in this type of soil. The assessment of machine in this type of soil has shown much better result than compared to other soil conditions. It has been found that the time required for planting one hectare of loamy dry soil requires around 20hrs. Thus the machine gives 100% efficiency in loamy dry soil.

Wet soil

Soil sometimes may get extremely wet due to heavy down fall or excessive irrigation in such cases the planting was mostly not done unless some avoidable circumstances in such cases it was found that the machine' wheel get sticked to the ground and makes it difficult to move. Thus it is found that the efficiency of machine is less in wet soil.

5.3 RESULT

After all the assessment process it has been found then the efficiency of machine decreases with increase in the wetness of the soil and vice versa. This machine cannot be used in the land where heavy rainfall occurred or the soil is highly wet.

Usually sugarcane is planted straight before ploughing the land, only after the planting was over, the field is irrigated along ridges and furrows. The planting was also not done where the rainfall has occurred recently and the land is still wet. So the lower efficiency of the machine in wet soil does not affect the efficiency of the machine greatly in practical use.

Thus this machine attained its goal for the purpose of which it had been designed and fabricated. There is no doubt that this machine will greatly help the sugarcane cultivating farmers of India when it is modified and re-fabricated related to the commercial needs.

CHAPTER 6

CONCLUSION

This project work has provided us an excellent opportunity and experience, to use our limited knowledge. We gained a lot of practical knowledge regarding planning, purchasing, assembling and machining while doing this project work.

We are proud that we have completed the work with the limited time successfully. The **"DESIGN AND FABRICATION OF SUGARCANE CHIPPING CUM PLANTING MACHINE"** is working with satisfactory condition. We are able to understand the difficulties in maintaining the tolerances and also quality.

We have done to our ability and skill making maximum use of available facilities. By using more techniques, it can be modified and developed according to the application.

ABSTRACT

Green gram (*Vigna radiata L.)* is the third most important pulse crop of India both in terms of area and production next to chickpea and pigeon pea. It is cultivated in kharif, rabi and summer seasons in different parts of the country. The production of pulse crops in India in general is not enough to meet the domestic need of the ever growing population. Green gram contains 25 percent protein, this being about two third of the protein content of soybean, twice that of wheat and thrice that of rice. The productivity is far below the potential and there is substantial scope for improvement with the adoption of improved technologies. The protein is comparatively rich in lysine, which is deficient in cereal grains. Among various improved technologies, the application of nutrient through foliar application of RDF + Water control spray(T1), RDF + Foliar application of Nitrobenzene 2% at 25 and 45 DAS(T2), RDF + Soil application of DAP at 2% 25 and 45 DAS (T3), RDF + Salicylic acid at 75ppm spray (T4), RDF + Urea at 2% + Nitrobenzene 2% + Salicylic acid at 75ppm spray (T5), RDF + 25kg of extra dose of nitrogen at 40 DAS + foliar application of DAP 2% at 25 and 45 DAS(T6) to increase the yield as well as nutrient use efficiency is considered to be an effective and economic method of supplementing part of nutrient requirement at critical stages. An uniform dose of RDF was applied to all the plots as basal.

An investigation entitled "Agrotechniques for maximizing yield in Green Gram" to study the effects of foliar nutrition on growth, yield, quality and economics of green gram in acid soil. The experimental was laid out in a Randomized Block Design with six treatments replicated thrice and the variety was Co8.

CHAPTER 1

INTRODUCTION

India is the largest producer and consumer of pulses in the world accounting for 32 per cent of world area and 25 per cent of production. Nearly 8 per cent of the pulse area is occupied by green gram, which is the third most important pulse crop of India in terms of area cultivated and production next to chick pea and pigeon pea. Against the production of 19.78 million tonnes during 2013-14 (from 25.21 million hectare area), consumption of pulses in India has been around 22-23 million tonnes. Thus India needs to import pulses every year to fulfil the domestic demand. Pulses estimation for Indian in 2018-19 25.19. Domestic production of major pulses is Green gram. Production trend of pulses in India is 25230.00. India's export and import of pulses is 248.01. It is estimated that Indian population will be around 1460 million by 2030 and demand for pulses would further grow in the years to come. The production of pulse crops in India in general and especially green gram in particular is not enough to meet the domestic demand of the ever growing population. The present productivity is far below the potential and provides substantial scope for improvement with the adoption of improved technologies. Among various other factors, application of nutrients through foliar application which increases the fertilizer use efficiency, thus increasing yield and reducing cost of production in pulses. This is considered to be an efficient and economic method of supplementing part of nutrients requirements at critical stages.

Green gram contains about 25 per cent protein, this being about two third of the protein content of soybean, twice that of wheat and thrice that of rice. The protein is comparatively rich in lysine, which is deficient in cereal grains. Hence, a diet combining green gram and cereal grains forms a balanced amino acid diet. Every 100 g of green gram seeds contains 132 mg calcium, 6.74 mg iron, 189 mg magnesium, 367 mg phosphorus and 124 mg potassium and vitamins like 4.8 mg ascorbic acid, 0.621 mg thiamine, 0.233 mg riboflavin, 2.251 mg niacin, 1.910 mg pantothenic acid and 114 IU vitamin A. It is also used as green manure crop. Being a legume, it has the capacity to fix the atmospheric nitrogen (30-50 kg/ha). It also helps in preventing soil erosion. India is producing 1.61mt. of green gram from an area of 3.38m.ha with an average yield per hectare of 474 kg (IIPR, Kanpur 2013-14). Jharkhand accounts for production of 637 kg per hectare green gram from an area of 16.1 (000'.ha) with productivity of 10.3 Important green gram growing states in India are Rajasthan, Odisha, Andhra Pradesh, Maharashtra, Tamil Nadu, Madhya Pradesh, Gujarat, Karnataka, and Bihar among which Rajasthan occupies larger area and production (1020 thousand ha and 391.2 thousand tonnes,

respectively). Tamil Nadu leads first in productivity with an average yield of 775 kg ha-1. Evaluation of suitable management practices to increase the productivity of pulses even under rain fed situation is essential. The yield potential of green gram is very low because of the fact that the crop is mainly grown in rain fed conditions with poor management practices and also due to various physiological, biochemical as well as inherent factors associated with the crop.

Apart from the genetic makeup, the physiological factor viz., insufficient portioning of assimilates poor pod setting due to the flower abscission and lack of nutrients during critical stages of crop growth, coupled with a number of diseases and pests (Mahala et al., 2001) were the reasons for the poor yield. The reasons for low yield of greengram are the slow rate of dry matter accumulation during the pre-flowering phase, poor pod setting, onset of leaf senescence during the period of pod development and low partitioning efficiency of assimilates to grain were identified as the main physiological constraints for yield.

OBJECTIVE

Main objectives in this study were to:

- To study the effect of foliar nutrition on growth yield and quality of green gram.
- To work out the economics of foliar nutrition in green gram cultivation
- To evaluate fertility status of soil after the harvest of the crop.

CHAPTER 2

REVIEW OF LITERATURE

KUMAR, P. NAIDU, S. RAHMAN, R. DOSS, A. AHAMED AND S. KAUR (2017) **entitled as "EFFECT OF FOLIAR APPLICATION OF NUTRIENTS ON GROWTH" said ,** The reported that growth attributing characters i.e plant height, branches/plant, root length, number and dry weight of root nodules, recorded higher values with the foliar application of DAP 2 % spray at flowering and 15 days later. Another recorded maximum plant height (20.24 cm) and dry matter accumulation (4.22 g/plant) in green gram with foliar application of urea @ 2% and it was at par with the foliar application of KNO3 @ 1% and it may be due to availability of nitrogen and potassium to the plant through foliar spray and potassium also regulate the osmotic tumour of cells and water balance which is driving force for cell division and elongation. Significantly higher leaf area index (5.82), leaf area duration (136.54 days), total dry matter production (39.36 g), plant height (25.75 cm), number of leaves per plant (64.66) and number of branches per plant (9.73) recorded with recommended dose of fertilizer along with foliar application of urea in groundnut and it may be due to the foliar application of nitrogen enhancing the accumulation and translocation of assimilates which resulted in prolonged vegetative phase and better photosynthetic capacity of the plant..Another report found that the combined foliar application of B, Mo, and Zn significantly increased plant height, dry matter and number of branches per plant in common bean and it might be due to micronutrient involvement in various physiological processes such as, enzyme activation, chlorophyll formation, electron transport and stomata regulation. Foliar treatment of 20:20:20 (N:P2O5:K2O) increased the plant height (29 cm), number of branches per plant (3.3), number of leaves per plant (11.6), root length (6 cm) a plant weight (4.6 g) in common bean. Sujatha (2001) reported that foliar application of salicylic acid (100 ppm) on green gram at 75 DAS increased the plant height (50.4 cm), root length (16.9 cm), number of leaves (18.4) and Leaf area index (LAI) (1.30). He reported that the growth parameters viz., LAI in green gram were significantly higher with the foliar spray of KNO3 (1 per cent) or KCl (1 per cent) and their combination. He reported that there was a pronounced inhibition of shoot growth by salicylic acid seed treatment in green gram. Foliar spray of 2 per cent DAP twice with recommended dose of fertilizer recorded the maximum plant height of green gram reported higher plant height (17.8 cm) in green gram due to foliar application of 1 per cent KCl twice at flowering and pod formation stages with basal N and P application followed by 2 per cent DAP + 1 per cent KCl spray. He stated that foliar spraying of 1 per cent urea significantly increased the crop growth rate (CGR) in soybean and he

observed that the foliar application of 1 per cent urea and 50ppm NAA significantly influenced the specific leaf area in soybean. A similar result was reported by Baghel and Yadhav (1992) with NAA in green gram. Another report observed that DAP at 50 kg per hectare at basal dose followed by foliar spray of urea and DAP twice significantly increased the leaf area index (LAI) and dry matter production during both kharif and summer seasons. The yield attributes were significantly higher when urea or DAP foliar spray was given in mung bean. Foliar application of MOP increased plant height and dry matter accumulation in pigeonpea. It also reduced flower drop in all the cultivars of pigeonpea because K increases cell expansion by regulating the solute potential and consequently the turgor potential which increases the rate of leaf expansion and also the total leaf area per plant and reduce flower drop. Potassium also involved in efficient translocation of photosynthates due to which dry matter accumulation also increases (Satyanarayana).

From our report, revealed that foliar application of salicylic acid (150 ppm) and urea enhanced plant height and number of branches per plant in green gram at 45DAS and 60DAS.

SIVA, JADHAV, TAHIR, GOWDA, CHAUDHARY, MONDAL AND MANOMARI (2017) **entitled as "EFFECT OF FOLIAR APPLICATION OF NUTRIENTS ON YIELD ATTRIBUTES"** said as reported significantly higher number of pods per plant with the foliar spray of panchagavyam and it was at par with foliar spray of 19:19:19 and also higher test weight in green gram. Significantly higher dry pod yield (4361 kg/ha), number of filled pods per plant (24.27), total number of pods per plant (29.53), 100 pod weight (135.33 g) and 100 kernel weight (41.16 g) were recorded with recommended dose of fertilizer along with foliar application of urea in green gram and it may be because of the additional amount of nitrogen supplied through the foliar application at 45 DAS and 60 DAS, which in turn might have met the required nitrogen demand of the crop during flowering and post flowering period of groundnut. This in turn might have resulted in greater availability, absorption, assimilation and translocation of nitrogen for increased photosynthesis and ultimately yield attributes were increased. Application of 100% recommended dose of NPK + 2% DAP + TNAU pulse wonder 5.0 kg per ha, had significantly increased plant height (37.62 cm), number of pods per plant (37.15), number of flowers per plant (50.12), and fruit setting percentage (72.55%) in green gram, it might be due to the balanced metabolism maintained continuously inside the plant to subsequent phases of growth. Another reported that the number of seeds per pod (10.80), 1000 grain weight (40.97 g) were found maximum in mash bean when 2% DAP + 1% K applied twice as foliar spray and it might be due to the effect of potassium on photosynthetic activity and potassium also play an important role in the translocation of photosynthesis and it has the ability to develop bold seed .

Similarly He revealed that the number of seeds per pod significantly increased with the application of potash. He found that the foliar application of 19:19:19 @ 0.4% along with soil application of ZnSO4 in pigeon pea recorded significantly higher number of pods per plant (251.07), number of seeds per pod (3.41), 100 seed weight (10.89 g) and seed yield (37.18 g plant-1) and the result showed that foliar spray of N, P and K significantly increased number of pods/plant, number of seeds / pod, biomass and grain yield. It may be concluded that foliar spray of N, P and K is the suitable application for the maximum yield of green grams.

From our literature, we use RDF and foliar application of nitrobenzene is the application for the maximum yield of green gram.

JADHAV AND KULKANI, SRITHRAN, BHOWNICK, VENKATESH AND TAHIR (2016) **entitled as "EFFECT OF FOLIAR APPLICATION OF NUTRIENTS ON QUALITY" said as,** He reported that the indicated that foliar sprays of 2 per cent DAP, 2 per cent urea and 2 per cent KCl remained at par and resulted in higher seed yield, net returns, protein content, nitrogen, phosphorus and potassium content in seed and straw and total uptake of nitrogen, phosphorus and potassium over water sprayed control. Another observed that foliar spray of 2% DAP + 40ppm NAA at 45 and 55 days after sowing recorded significantly higher grain protein content (24.45%) in green gram. Another report that the effect of foliar application of urea on growth, yield and quality of chickpea and recorded an increase in grain protein content of 17.88 to 19.31 per cent which was due to increased nitrogen availability for seed filling. He reported that in green gram at 50% flowering stage, nitrate reductase activity (NRA), Relative Water Content (RWC) were estimated and found maximum in 1.0% urea spray. All the genotypes significantly improved their NRA, RWC and chlorophyll content in leaf with increase in urea concentration up to 1%. He observed that, foliar spray of DAP two per cent + NAA 40 ppm + B 0.2 per cent + Mo 0.05 per cent at 30 DAS resulted in significantly increasing the protein content over control in green gram. He revealed that treatment of one per cent urea foliar application at pod filling resulted in highest protein content in seed (25 per cent) in green gram. Another reported that foliar spray of Navaras, Nuspartin, Tracels, urea and DAP enhanced the yield, and yield attributing characters, protein content of the grains in black gram. Protein content of the grains was highest with urea spray. Two sprayings Viz., at 20 and 80 DAS recorded the higher protein content of grain (23.04%) over a single spray at 20 or 30 days after sowing. Another report, observed that foliar spray of KNO3, thiourea and DAP increased the protein yield without affecting the oil content in soybean in moderate saline or alkaline soil.

From our literature, we use water for nutrients growth and increased the protein yield, increase chlorophyll content in leaf, enhance the yield.

SRITHARAN, SHASHIKUMAR, SINGH, CHAUDHARY AND YADAV, RAJAVEL AND VINCENT (2015) **entitled as "EFFECT OF FOLIAR APPLICATION OF NUTRIENT ON YIELD" said as,** He reported significantly higher grain yield of green gram with the foliar spray of 19:19:19 (1121 kg/ha) followed by panchagavya (1103 kg/ha) compared to rest of the treatments in green gram. Another reported that application of DAP 2 % spray at flowering and 15 days later recorded highest grain yield (916 kg /ha), straw yield (1527kg/ha) and harvest index (37.49%). He found that the foliar spray of 2% urea provide significantly highest yield (900 kg/ha) in black gram and yield increment was 20% over control and it might be due to improved morphophysiological traits and yield attributes. He revealed that spraying of 2 per cent DAP at 30 and 45 DAS recorded significantly higher seed yield (1094 kg/ha) over no spray (1050 kg/ha). The increased seed yield with 2 percent DAP was mainly due to the increased nutrient supply and reduced nutrient losses. He observed that application of 60 kg K2O ha–1 at sowing and combined foliar spraying of 2% urea and 0.25% multiplex at pre-flowering stage of chickpea resulted in maximum grain yield and ancillary characters. He reported that among foliar treatments, 2% urea spray (twice) at pre-flowering stage and 10 days thereafter could significantly produce the highest seed yield (1040.00 kg ha-1) and was closely followed by 2% DAP spray (983.75 kg ha-1) proved to be effective in improving growth and productivity of lathyrus in rice-utera system. He found that the foliar application of 2% urea at 75 DAS recorded highest seed yield (2437 kg/ha) and followed by 2% DAP spray at 75 DAS (2389 kg/ha) in chickpea. It may be because urea application contributed towards overall biomass production under rainfed condition. Five concentrations of water soluble fertilizer (19:19:19) i.e. no foliar spray (control), 0.25%, 0.5%, 0.75% and 1.0% applied at three critical crop growth stages (peak flowering, pod development and at pod filling stage). The result reveals that the grain yield (1661 kg/ha) was significantly higher with foliar application of 1.0% (19:19:19) followed by 0.75% and 0.50% (1518 and 1454 kg/ha respectively). But there was no significant difference observed due to the stages of spray application. The higher yield with 1.0% WSF was due to higher number of pods per plant (121.8), pod weight per plant (105.5 g), grain yield per plant (19.9 g), plant height, higher number of branches, leaf area and higher total dry matter production at harvest of green gram. Singh, (2013) reported that application of 25 and 37.5 kg P2O5/ha increased grain yield by 10.3 and 15.8% over no application of phosphorus in black gram. However, the differences between 25 and 37.5 kg/ha were non-significant during both the years. Though 2% urea spray improved the grain yield by, on an average, 3.0% over unsprayed control yet the differences were significant only in 2004. Foliar treatment of NPK (20:20:20)

increased grain yield (813 kg/ha) in common bean and it might be due to N: P:K enhances the plants vegetative growth and improve the ability of the plant for the synthesis, storage and translocation of nutrient from one part to other parts of the plant. Similar results were reported by Manivannan et al., (2002); Anitha et al., (2005); Zafar and Fayyaz (2007); Alam et al., (2010) and Saeed et al., (2013). They also reported that maximum biological yield (2423 kg/ha) by the foliar application of NPK. He studied the effect of foliar application of urea on physiological characters and yield of soybean and revealed that foliar application of urea @ 1.5% three times at reproductive stages may be used for getting increased seed yield in soybean (3.19 t/ha). He reported significantly higher seed yield of cowpea (1227 kg/ha) was recorded with foliar spray of 2% DAP, but remained at par with 2% urea (1189 kg/ha) and 2% KCl (1177 kg/ha). Similarly, foliar spray of 2% DAP, urea and KCl recorded significantly higher straw and biological yields and harvest index as compared to control. Rajavel and Vincent (2009) investigate that foliar spray of 2% urea recorded the highest yield of 955 kg/ha followed by foliar spray of KCl 1% along with soil application of humic acid @ 20 kg/ha (926 kg/ha). Application of PGR and nutrients increased the growth characters viz., Crop Growth Rate (CGR), Net Assimilation Rate (NAR), Leaf Area Development (LAD) at all growth stages. The yield enhancement may be due to improved morphological, physiological and biochemical parameters. The tested chemicals particularly 2% urea was found effective towards yield maximization in green gram. He observed that the foliar application of 2% DAP+ 1% KCl twice at flowering and pod filling stage in black gram recorded significantly higher grain yield (1007 kg/ha). The Percentage increase in grain yield was 32.8% over control and it might be due to the enhancement in growth and yield parameter as well as uptake of nutrients by crop. Obviously, cumulative effects of these parameters might have contributed to increased grain yield potential of the green gram.

From literature, we use RDF and Foliar application of nitrobenzene increase the grain yield per plant, plant height, and higher number of branches, leaf area and higher total dry matter production at harvest of green gram.

LIMBIKAI, SHASIKUMAR, DIXI AND RAMAN, VEERABHADRAPPAM, PENG (2017) **entitled as "EFFECT OF FOLIAR APPLICATION OF NUTRIENTS ON NUTRIENT UPTAKE" said as,** found that the foliar application of 19:19:19 (N:P2O5:K2O) @ 0.4% along with soil application of ZnSO4 in green gram recorded significantly higher uptake of N (126.66 kg/ha), P (45.73 kg/ha) and K (47.02 kg/ha). He indicated that application of recommended dose of fertilizers (RDF) as a basal dose and foliar spray of 40ppm NAA+0.5% chelated micronutrient+2% DAP given at 35 and 50 DAS recorded significantly higher phosphorus and potassium uptake (88.32, 10.72 and 35.09 kg ha-1 respectively). He observed that foliar spray of 2% DAP + 40ppm NAA at 45 and 55 days after sowing recorded significantly higher total uptake of nitrogen (76.38 kg/ha), phosphorous (10.66 kg/ha) and potassium (27.42 kg/ha) and sulphur (5.17 kg/ha) in black gram. He observed that nutrient uptake by green gram was higher at 45 DAS and reduced at harvest stage in which N, P and K uptake was 17.8 kg, 3.65 kg and 20.5 kg ha-1 respectively when the plants are supplied with 0.05 g sodium molybdate + 2 per cent DAP +100ppm Salicylic acid. Higher leaf nitrogen content (3.46 per cent) was recorded with three foliar application of urea sprayed at 60, 75 and 90 DAS than the control (3.16 per cent) under rainfed conditions in green gram. He observed that the foliar application of 2% DAP + 1% KCl twice at flowering and pod filling stage registered significantly higher N uptake (64.64 kg/ha), P uptake (6.75 kg/ha) and K uptake (46.51 kg/ha) in black gram and it might be due to increased supply of nutrients and good response of the plant to them. Increased NPK uptake due to foliar application was also observed by him. He observed that, foliar spray of DAP two per cent + NAA 40 ppm + B 0.2 per cent + Mo 0.05 per cent at 30 DAS resulted in significantly increasing the NPK uptake over control in green gram.

From our literature, we use RDP and foliar application of nitrobenzene increasing the nitrogen content uptake over control in green gram.

SHASHIKUMAR, LIMBIKAI, MUTHUVEL **entitled as "EFFECT OF FOLIAR APPLICATION OF NUTRIENTS ON SOIL STATUS" said as,** He indicated that application of recommended dose of fertilizers (RDF) as a basal dose and foliar spray of 40ppm NAA+0.5% chelated micronutrient+2% DAP given at 35 and 50 DAS recorded significantly higher available N and P2O5 content of soil (278.13 and 28.55 kg ha-1 respectively). He observed that foliar spray of 2% DAP + 40ppm NAA at 45 and 55 days after sowing recorded higher available N,P,K and S status of soil (240, 26.17, 300.17 and 37.17 kg ha-1 respectively) in green gram. He reported that, foliar spray of 2% DAP and 1% urea at flowering stage, increased the available N, P and K status of soil (131, 6.3 and 134 kg ha1, respectively) of rain fed green gram compared to no foliar spray.

From this literature, we use that the application of recommended dose of fertilizers as a basal dose and foliar spray of 2% DAP increased the flowering stage, increased the available N, P and K status of soil in green gram.

GOWDA, VINOTH KUMAR, GUPTA, DESHMUKH, THAKARE, PARASURANAM **entitled as " EFFECT OF FOLIAR APPLICATION OF NUTRIENTS ON ECONMICS" said as,** He reported that foliar spray of 19:19:19 recorded significantly higher net return (35838 `/ha) and B: C ratio in green gram. He reported that application of DAP 2 % spray at flowering and 15 days later recorded highest gross return (41221`/ha), net profit (23313 `/ha) and B:C ratio (1:2.30) in green gram. and found that the foliar application of 19:19:19 @ 0.4% along with soil application of ZnSO4 in pigeon pea recorded significantly higher gross return (55592 `/ha), net return (36323 `/ha) and B: C ratio (2.89). Another report indicated that application of recommended dose of fertilizers (RDF) as a basal dose and foliar spray of 40ppm NAA + 0.5% chelated micronutrient+2% DAP given at 35 and 50 DAS recorded significantly higher net returns and B/C ratio (` 52,900 ha-1 and 3.03 respectively), over rest of the treatments but it was at par with RDF + foliar spray of 2% DAP+0.5% chelated micronutrient. Foliar application of DAP (2%) and RDF gave maximum net income up to 51,201 `/ha.. He revealed that the foliar spray of 2 % DAP on soybean recorded significantly higher net return of ` 20,090 with B:C ratio of 2.22 and studied the effect of fertility levels and foliar nutrition on profitability, nutrient content and uptake of cowpea and concluded that foliar spray of 2 % DAP recorded higher net returns (24039 `/ha) compared to 2% urea and 2% KCl. Foliar application of 2% DAP + 100ppm salicylic acid + 0.05% sodium molybedate twice at vegetative and flowering stage proved to be the most promising nutrient management practice for summer green gram in terms of gross return and net return (11519 `/ha). Experiment conducted on sandy loam soil of Allahabad to study the effect of foliar spray of DAP and growth regulators on yield attributes indicated that, 2% foliar spray of DAP and NAA 40 ppm twice at 25 and 35 days after sowing resulted in higher benefit cost ratio (2.58) in green gram (Behera et al, 2007). boron@ 0.2 per cent and molybednum 0.05 per cent as foliar spray on green gram and study the effect of two per cent DAP, NAA 40 ppm, results revealed that foliar spray of DAP two per cent + NAA 40 ppm + B 0.2 per cent + Mo 0.05 percent at 30 DAS resulted in higher benefit cost ratio (1.97) over control (1.45) on sandy loam soil during rainy season at the Allahabad Agricultural Institute.

From literature, we use application of DAP spray at flowering recorded high gross return.

CHAPTER 3

METHODOLOGY

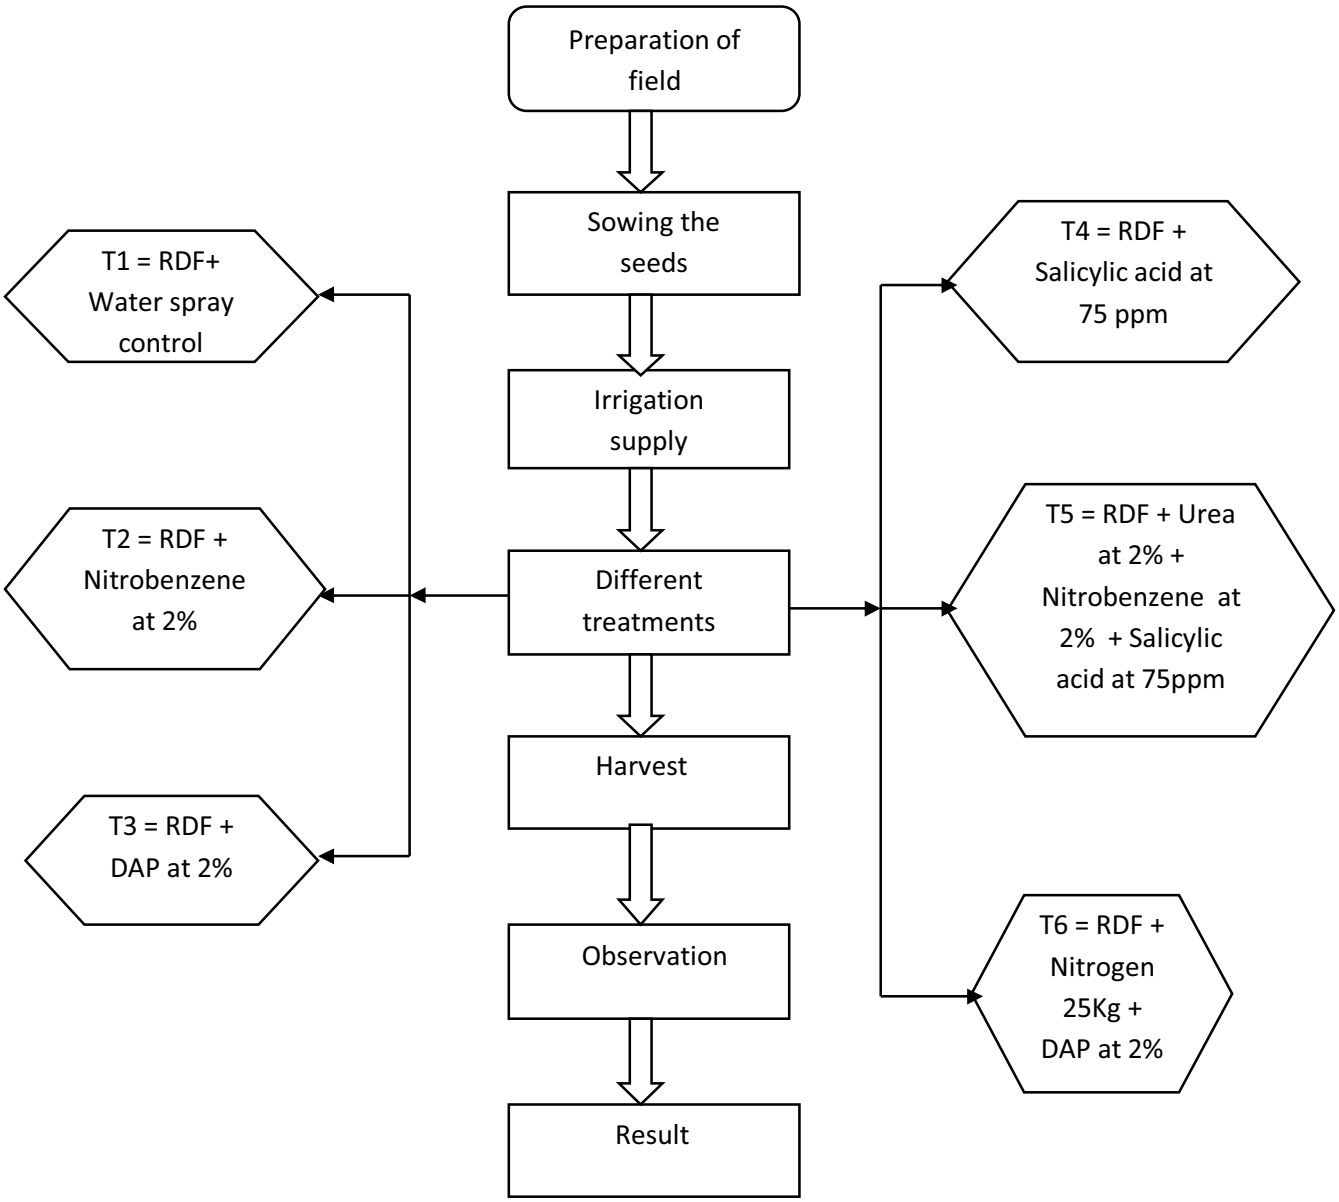

Fig.1: Flowchart

3.1 PREPARATION OF FIELD:

Experimental location

The experiment was conducted at the Paavai Engineering College at Namakkal. Its latitude (11.2195158) and longitude (78.167793). It is a clay soil and a soil ph of about 5.2 to 8.7. The experimental plots had assured irrigation facility coupled with uniform topography, good drainage and soil characteristics which is typical suitable for green gram cultivation.

An area of 34*21 ft or 68.4 m2 portion of the farm site was ploughed. The experiment was laid out in Randomized Block Design with six treatments replicate twice.

Prepare the land to get fine tilth by power tiller and form beds and channels. Apply lime @ 2 t/ha of FYM to prevent surface soil crusting.

.

Details of layout plan

DESIGN	RANDOMIZED BLOCK DESIGN
Treatment	Six
Replication	Four
Net plot size	34*21 ft
Seed rate	25kg
Spacing	30*10cm

Table 3.1: Details of layout plan

Fig.1: layout of field

3.2 SOWING:

The experimental green gram was sown on 15th December 2019 using 25kg seeds per hectare. Two seeds were by dibbling them in furrow opened at a spacing of row to row is 30cm and plant to plant spacing is 10cm. Seeds were then covered with soil manually.

Variety:

The variety of green gram is Co8. The maturity days of crop is 60-65 days.

Soil:

Green gram can be grown on a variety of soils ranging from sandy loam to black cotton soils having a good drainage capacity. Saline and alkaline soils are not suitable for green gram cultivation. Green gram is very sensitive to water logging conditions.

Soil and Climatic requirement:

Green gram is a tropical pulse crop largely grown under semi arid and subtropical environment with annual rainfall of 60-75cm. It is a short day plant, can be grown in temperature between 20 to 40 c and optimum temperature is 28 to 30 c. Grown from sea level to 2000MSL. Ideal soils are well drained loam or sandy loam and saline alkali soils are not suitable. Opimum pH range is 6.5 to 7.5cm.

Seed selection:

Seeds used for cultivation must be from a genuine authorized source which will help you to select proper seed that has genetic purity and seeds must be vigorous to have good field stand. In the process of seed selection, one must check for diseased seeds, hard seeds, shrunken seeds immature seeds, deformed seeds.

Seed rate and sowing:

Seed rate and spacing depends on the,

- Seeds can be sown in line sowing.
- Flat beds. The seeds are dibbled at 2-3 cm depth at spacing 30*10cm in flat beds
- Seed rate on the variety of seed and that may vary from 25kg per hectare.

Seed Treatment:

With Carbandazium or Thiram @ 2g/kg of seed then after interval of 24 hours treat with 3 packets (600g) suitable strains of rhizobium biofertilizer with rice gruel 15 minutes before sowing.

Instead chemical, treat with Trichoderma viride @ 4g/kg or Pseudomonas fluorescence @ 10g/kg followed by bifertilizeer treatment.

For pre-monsoon sowing, seed treatment with paste made of ash (500g/kg of seeds) plus 3% gum followed by 5 hrs drying is recommended.

Spacing:

The spacing of green gram is 30cm*10cm

Irrigation:

Irrigate immediately after sowing, followed by life irrigation on the third day. Irrigate at intervals of 7to 10 days depending upon soil and climatic conditions. Flowering and pod formation stages are critical periods when irrigation is a must. Avoid water stagnation at all stages. . Apply KCl at 0.5 per cent as foliar spray during vegetative stage if there is moisture stress.- metabolism of nitrogen-containing compounds by animals and is the main nitrogen-containing substance in the urine of mammals. It is a colourless, odourless solid, highly soluble in water and practically non-toxic (LD50 is 15 g/kg for rat). Urea is widelyRecommended dose of fertilizer (RDF) – 25:50:0 (N:P2O5:K2O)

Source of fertilizer – N from Urea, P2O5 from DAP, K2O from MOP

Fig.2: Irrigation supply

After cultivation practices:

Gap filling:

If there is no germination within seven days of sowing and there is gap then fill that gap by dibbling the green gram seeds. Also during thinning fill the gap by planting the green gram plants.

Thinning:

In irrigatedgreen gram at the time of dibbling 2-3 green gram seeds are sow dibbled. Therefore it is necessary to carry out thinning operation within 7 days of sowing keeping only two healthy pplnts at each hill.

Weeding:

One or two inteculturing and one or two weeding should be carried out at 20 and 45 days after sowing. Fluchloralin or Pendimethalin @0.5kg per hectare or Oxadiazon @0.25kg per hectare as pre-emergence should be applied when hand weeding is not possible due to continuous rains during kharif season under middle Gujarat conditions. In wheat-moong cropping sequence, apply Flurchloralin @0.9kg per hectare as pre-emergence and carry out two hand weeding at 20-30 DASs in summer green gram.

Cropping system:

Green gram is taken in a crop sequence of sorghum-wheat-green gram, sorghum-potato-green gram or pearl millet-wheat-green gram.

3.3 TREATMENTS DETAILS:

Symbols	Treatments
T1	RDF + Water spray (control)
T2	RDF + foliar application of Nitrobenzene @ 2% at 25 and 45 DAS
T3	RDF + DAP @ 2% spray at 25 and 45 DAS
T4	RDF + Salicylic acid @ 75ppm at 25 and 45 DAS
T5	RDF +Nitrobenzene + Urea @ 2% + Salicylic acid @ 75 ppm spray at 25 and 45 DAS
T6	RDF + 25kg of extra dose of nitrogen at 40DAS + DAP @ 2% spray at 25 DAS

Table 3.2: Treatment details

3.4 DETAILS OF FOLIAR NUTRIENTS

3.4.1 Urea

Urea or Carbamide is an organic compound with the chemical formula CO (NH2) 2. Urea serves an important role in the used in fertilizers as a convenient source of nitrogen. Its nutrient composition is 46% N.

3.4.2 D.A.P

Di ammonium phosphate (DAP) with chemical formula (NH4)2HPO4 and IUPAC name diammonium hydrogen phosphate is one of a series of water-soluble ammonium phosphate salts that can be produced when ammonia reacts with phosphoric acid. Its nutrients composition is 46% P2O5 and 18% N respectively.

3.4.3 Salicylic acid:

Salicylic acid activates genes in some plants that produce chemicals that aid in the defence against pathogenic invaders. Salicylic acid contains GA and IAA which promotes cell replication. Trade name of salicylic acid is aspirin. Salicylic acid (from Latin salix, willow tree, from the bark of which the substance used to be obtained) is a mono hydroxybenzoic acid, a type of phenolic acid and a beta hydroxy acid. This colourless crystalline organic acid is widely used in organic synthesis and functions as a plant hormone. It is derived from the metabolism of salicin.

3.4.4 NPK (20:50:0)

NPK (20:50:0) is 1++00% water soluble fertilizers containing all the three major plant nutrients i.e. Nitrogen, Phosphorus and Potash for crops grown in green houses as well as other field crops. NPK is available in two forms: Foilar grade and drip grade.

1) Foliar, suitable for spraying.

2) Drip grade which is suitable for application through drip irrigation system.

Use of NPK either through drip or foliar prevents deterioration of soil texture as soil complexion and mechanical damage to the crop is eliminated

3.4.5 Nitrobenzene

It is a research based product containing nitrobenzene 24% w/w with naturally available vegetable protein. It is a plant energizer, flowering stimulants and yield booster. It enhances the plant canopy and induces profuse flowering and thereby increases the yield.

CHAPTER 4

BIOMETRIC OBSERVATION

4.1 Biometrics details:

The growth indices of plant were recorded at regular intervals throughout the life cycle of the crop in order to assess the probable relationship between different growth attributes and final yield. For recording biometric observations plant sampling were made at 20, 40 and 60 days after sowing (DAS) and at maturity. Five plants in the net plot area were randomly selected and tagged. The tagged plants were harvested for the studies of yield attributing characters of green gram. For recording the biometric observations such as dry matter accumulation of green gram, plants from the border rows were selected randomly drugged out from the second row of each plot to eliminate the border effect.

4.2 Pre-harvest observation

4.2.1 Plant height

In green gram, plant height of five randomly selected plants from each plot at 20, 40, 60 days after sowing (DAS) and at maturity were taken. Plants were measured from the ground level to the tip of the topmost leaf with the help of meter scale.The mean value of five plants was taken as the final plant height.

4.2.2 Dry matter accumulation

The five randomly selected plants from the second rows were cut above the ground at 20, 40, 60 days after sowing (DAS) and at maturity. The samples were dried in a hot-air oven at 65 ± 50 *C till the constant weight was obtained. The dry matter accumulation has been expressed in grams per m2.

4.2.3 Leaf area index (LAI)

It is defined as an assimilatory surface per unit area of land. Leaf area index was worked out at 20, 40 and 60 DAS by dividing the leaf area per plant by land area occupied by the plant.

$$LAI = \frac{\text{Leaf area per plant } (cm^2)}{\text{Land area occupied by plant } (cm)}$$

4.2.4 Number of root nodules per plant

The number of root nodules was counted on 40th day after sowing in randomly selected five plants. The plants were carefully removed from the soil without damaging the roots and roots were dipped in a bucket containing water to remove the soil and then nodules count was taken.

4.2.5 Number of branches per plant

Before harvest, five randomly selected tagged plants from each plot were taken out and number of branches of each plant was counted and arithmetic means were calculated.

4.3 Post harvest observation

4.3.1 Number of pods per plant

The numbers of pods in the five randomly selected plants were counted and arithmetic means of these five were recorded.

4.3.2 Number of seeds per pod

Total numbers of seeds from each of five randomly selected plants from each treatment were separated from pods and the number of seed is divided by number of pods.

4.3.3 100 seed weight

Seed samples were taken from the threshed and cleaned produce of each net plot and were exposed to sundry, 100 seed were counted and weighed to determine the 100 seed weight on electronic balance.

4.3.4 Grain yield

Harvested pods after picking from each net plot were threshed separately. After threshing, winnowing, cleaning and drying, Grain weight was recorded and concurrently grain samples were drawn from each plot to determine the moisture content with the help of moisture meter. Finally, the grain yield was computed at 14% moisture before being subjected to statistical analysis. The net plot yield was finally converted in to kg/ha by multiplying it with conversion factor.

CHAPTER 5

EXPERIMENTAL FINDINGS

The present investigation entitled "Effect of foliar nutrition on productivity of green gram (Vigna radiata L.)" was conducted during kharif 2020 at Agronomy Research Farm, Birsa Agricultural University, Ranchi. In this chapter, an attempt has been made to ascertain the degree of variations exhibited by different experimental variables applied in combination. Data thus obtained were analyzed and the statistical interpretations have been presented in this chapter.

5.1 Growth

Growth is an irreversible process in which there is an increase in size or dry weight or volume. Plant growth characters were evaluated in terms of plant height, nodule count, dry matter accumulation, leaf area index, number of branches and crop growth rate at different growth stages.

5.1.1 Plant Height

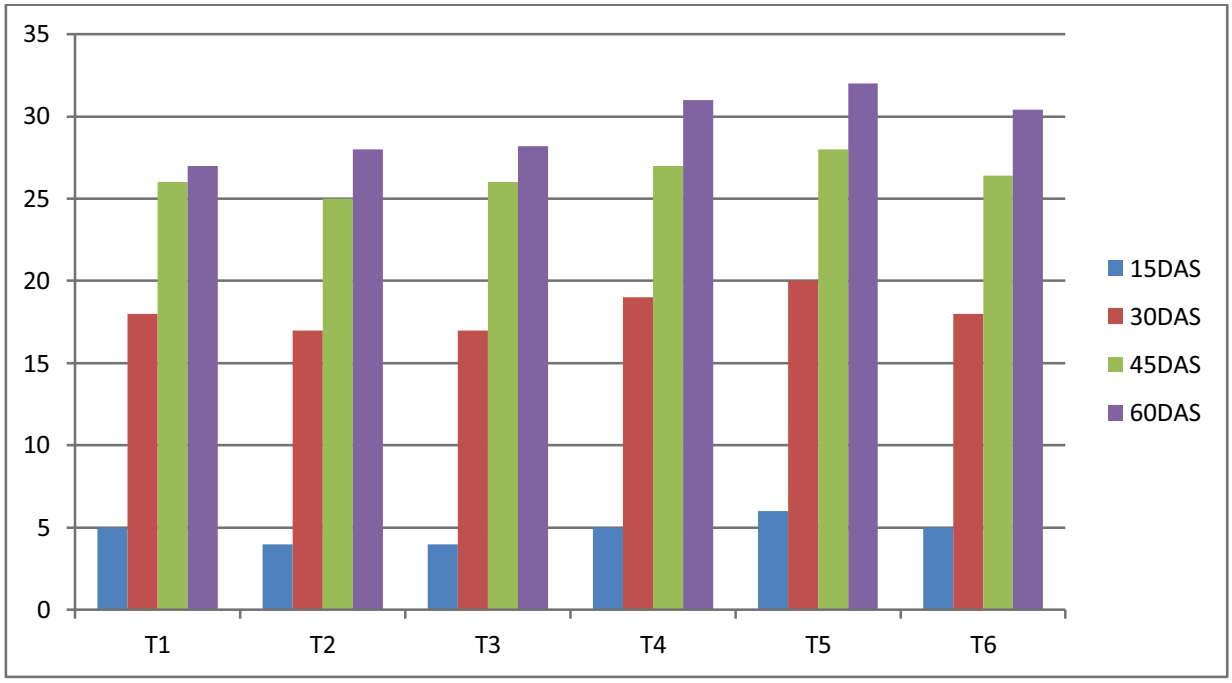
The data on plant height at progressive growth stages of green gram viz. 20, 40, 60 days after sowing and at harvest have been presented in Table 5.1. It is evident from data that at 20 DAS, plant height varied from 6cm to 32cm and was non-significant among the treatments. Maximum plant height (6cm cm) obtained with application of RDF + Nitrobenzene 2% + Urea @ 2% + Salicylic acid and minimum (4cm) with application of RDF + DAP @ 2%. At 30 DAS, plant height varied from 6cm to 28 cm and was significantly influenced by the foliar application of nutrients. Maximum plant height 32cm was obtained with application of RDF + Nitrobenzene 2% + Urea @ 2% + Salicylic acid @ 75ppm spray (T5), which was at par with RDF + Water spray control (26cm) , RDF + Foliar Application of Nitrobenzene @ 2% (T2) (25cm), RDF + Soil application of DAP @ 2% spray (T3) (26cm), RDF + Salicylic acid @ 75ppm spray (T4) (27cm), RDF + Nitrobenzene 2% + Urea @ 2% + Salicylic acid @ 75 ppm spray (T5) (28cm), RDF + 25kg extra dose of nitrogen + DAP @ 2% (T6) (26cm) ,except application of RDF + Water spray (control) (T1) and minimum (26cm) was obtained with RDF + Water spray (control) (T1). At later stages of crop growth i.e. 60 DAS, plant height varied from 28 cm to 32 cm and different treatments had significant effect on plant height. Maximum plant height (32cm) was recorded with RDF + Nitrobenzene 2% + Urea @ 2% + Salicylic acid @ 75ppm spray (T6), which was at par with RDF + Foliar application of nitrobenzene @ 2% (T2) (28cm), RDF + Soil application of DAP @ 2% spray (T3) (28cm), RDF + Salicylic acid @ 75ppm spray (T4) (31cm), RDF + Nitrobenzene 2% + Urea @ 2% + Salicylic acid @ 75ppm spray (T5) (32cm), RDF + 25kg of extra

dose of nitrogen + foliar application of DAP @ 2%, except application of RDF + Water spray(control) (T1) and minimum (27 cm) was obtained with RDF + Water spray(control) (T1).

At harvest, plant height varied from 27cm to 32 cm and different treatments had significant effect on plant height. Significantly higher plant height (32 cm) was obtained with application of RDF + Nitrobenzene 2% + Urea @ 2% + Salicylic acid @ 75ppm spray (T6) which is at par with all other treatments except application RDF + Water spray(control) (T1) and minimum (27 cm) was obtained with RDF + Water spray(control) (T1).

Treatments	Nutrient Management	15DAS	30DAS	45DAS	60DAS
T1	RDF + water spray control	5	18	26	27
T2	RDF + Nitrobenzene @ 2%	4	17	25	28
T3	RDF + DAP @ 2% spray	4	17	26	28.2
T4	RDF + Salicylic acid at 75ppm	5	19	27	31
T5	RDF + Nitrobenzene 2% + Urea @ 2% + Salicylic acid	6	20	28	32
T6	RDF + 25kg of nitrogen + DAP @ 2%	5	18	26.4	30.4

Table 5.1 :Observation of plant height



Graph.5.1: Observation of plant height

5.1.2 Leaf area index

The data on leaf area index presented in Table 5.2 revealed that there was variation among the treatment but significant variation was observed at 60 DAS as influenced by the foliar application of nutrients.

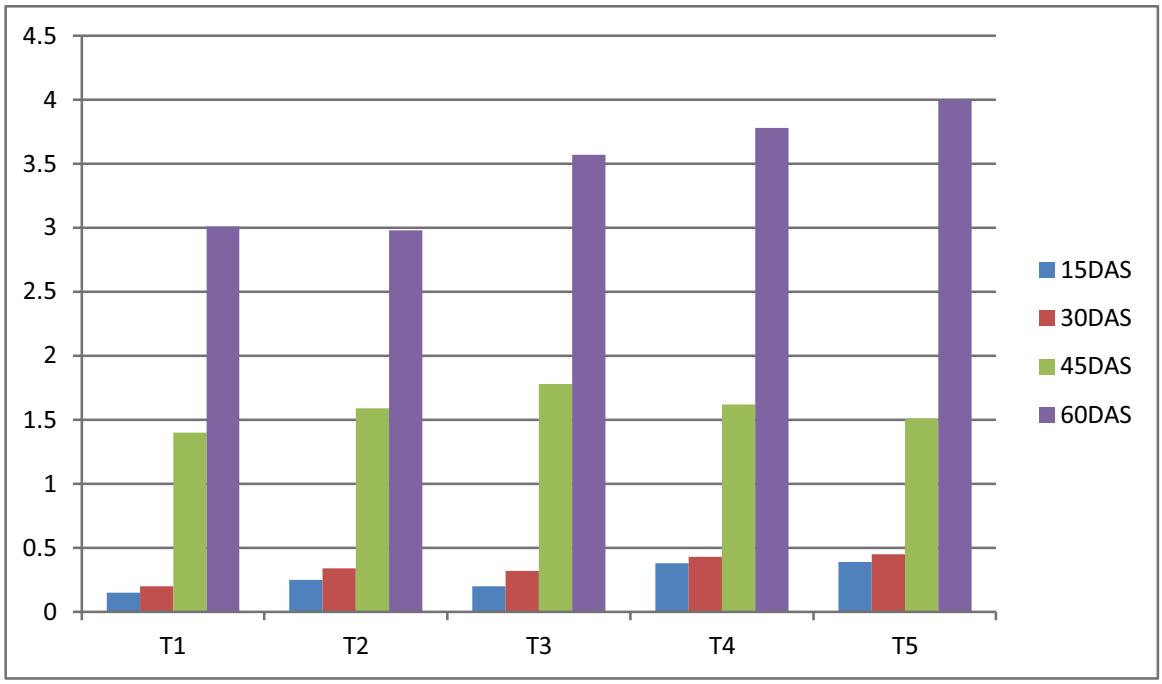
It is apparent from the data (Table 5.2) that, at 20 DAS leaf area index varied from 0.15 to 0.39 and was non-significant among the treatment. Maximum leaf area index (0.39) was recorded with application of RDF + Nitrobenzene 2% + Urea @ 2% + Salicylic acid @ 75ppm spray (T5), RDF + Salicylic acid @ 75ppm spray (T4) and minimum (0.35) with RDF + Water spray control (T1).

At 40 DAS, leaf area index varied from 1.40 to 1.98 and was non-significant among the treatment. Maximum leaf area index (1.98) was recorded with RDF + 25kg of extra dose of nitrogen + DAP @ 2% (T6) and minimum (1.40) with RDF + Water spray (control) (T1).

At 60 DAS, leaf area index varied from 3.01 to 4.00 and was significantly influenced by foliar application. Significantly maximum leaf area index (4.00) was produced with application of RDF + Nitrobenzene 2% + Urea @ 2% + Salicylic acid @ 75ppm spray (T6)which was at par with RDF + Foliar application of Nitrobenzene @ 2% (T2) (3.01), RDF + Soil application of DAP @ 2% spray (T3) (3.57), RDF + Salicylic acid @ 75 ppm spray (T4) (3.78), RDF + Nitrobenzene 2% + Urea 2 25 + Salicylic acid @ 75 ppm spray (T5) (4.00), RDF + 25kg of extra dose of nitrogen + Foliar application of DAP @ 2% while minimum leaf area index (2.98) was recorded with RDF + Water spray (control) (T1).

Treatments	Nutrient Management	15DAS	30DAS	45DAS	60DAS
T1	RDF + water spray control	0.15	0.20	1.40	3.01
T2	RDF + Nitrobenzene @ 2%	0.25	0.34	1.59	2.98
T3	RDF + DAP @ 2% spray	0.20	0.32	1.78	3.57
T4	RDF + Salicylic acid at 75ppm spray	0.38	0.43	1.62	3.78
T5	RDF + Nitrobenzene 2% + Urea @ 2% + Salicylic acid	0.39	0.45	1.51	4.00
T6	RDF + 25kg of nitrogen + DAP @ 2%	0.30	0.32	1.49	3.34

Table 5.2: Observation of leaf area index



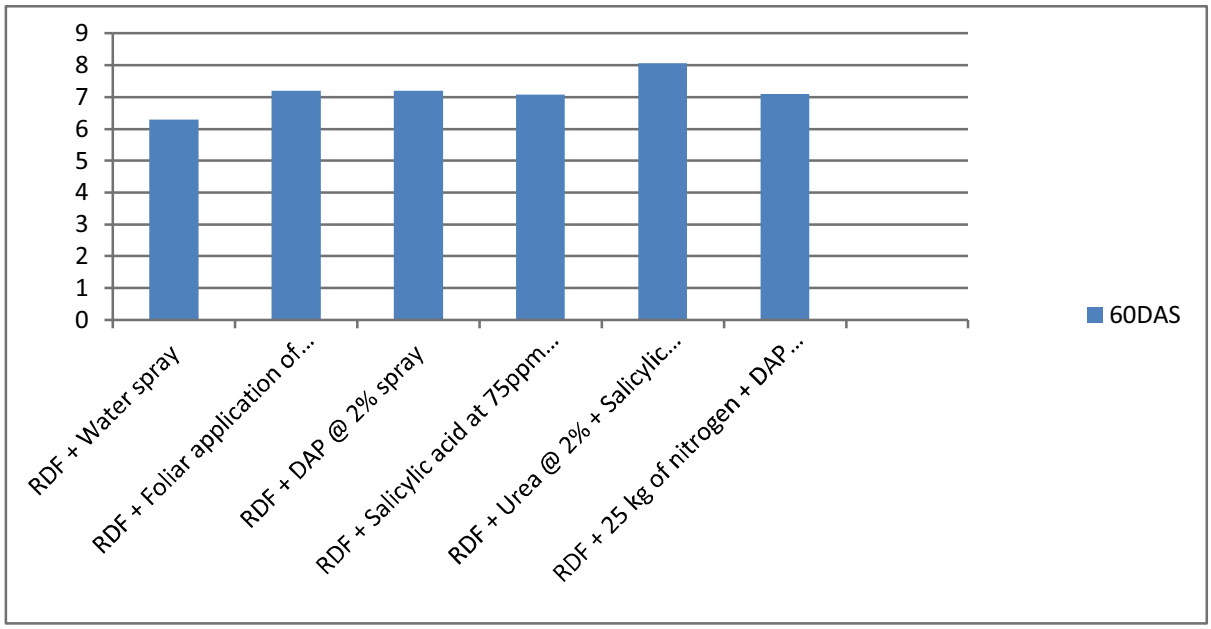
Graph.5.2: Observation of leaf index

5.1.3 Number of branches per plant

Data pertaining to number of branches per plant (Table 5.3) revealed that the foliar application of nutrients influenced the number of branches per plant significantly and varied from 6.30 to 8.07. At 60 DAS, significantly maximum number of branches per plant (8.07) was produced with application of RDF + Urea @ 2% + Salicylic acid @ 75ppm spray (T5) which was at par with RDF+ DAP @ 2% (T3) (7.20), RDF + Nitrobenzene @ 2% spray (T2) (7.20) and RDF + 25kg of extra dose of nitrogen + DAP @ 2% spray (T6) (7.10). Minimum number of branches per plant (6.30) was recorded with RDF + Water spray (control) (T1).

Treatments	Nutrient Management	60 DAS
T1	RDF + Water spray	6.30
T2	RDF + Foliar application of nitrobenzene @ 2%	7.20
T3	RDF + DAP @ 2% spray	7.20
T4	RDF + Salicylic acid at 75ppm spray	7.07
T5	RDF + Nitrobenzene 2% + Urea @ 2% + Salicylic acid at 75 ppm	8.07
T6	RDF + 25 kg of nitrogen + DAP @ 2%	7.10

Table 5.3 observation of number of branches per plant



Graph.5.3: Observation of branches per plant

5.2 Crop Growth Stages

5.2.1 Crop Growth Rate

Analysis of the data on crop growth rate as influenced by the foliar application of nutrients as presented in Table 4.6. The data revealed that crop growth rate increased as the growth progressed and the values being the maximum at harvest.

It is apparent from the data that foliar application of nutrients exerted significant influence on crop growth rate at all the growth stages. At 20-40 DAS, crop growth rate varied from 3.68 to3.87 g/m2/day. Maximum crop growth rate (3.87 g/m2/day) was observed with application of Urea @ 2% + Salicylic acid @ 75ppm spray (T6) along with RDF and the effect was non-significant with all the treatments. At 40-60 DAS, crop growth rate varied from 4.00 to 7.37 g/m2/day. Application of RDF + Nitrobenzene 2% + Urea @ 2% + Salicylic acid @ 75ppm spray(T6) recorded significantly maximum crop growth rate (7.37 g/m2/day) which was at par with RDF+ DAP @ 2% spray (T3) (6.64 g/m2/day), RDF + Nitrobenzene @ 2% spray(T2) (6.29 g/m2/day), RDF + Salicylic acid @ 75ppm spray(T4) (6.00 g/m2/day), RDF + 25kg extra dose of nitrogen + DAP @ 2% (5.75 g/m2/day), while minimum was recorded in RDF + Water spray (control) (T1).

At 60 DAS-harvest, different foliar treatments showed non-significant effect, crop growth rate varied from 3.49 to 6.52 g/m2/day. Maximum crop growth rate was observed with application of Urea @ 2% + Nitrobenzene 2% + Salicylic acid @ 75ppm spray (T6) along with RDF (6.52 g/m2/day).

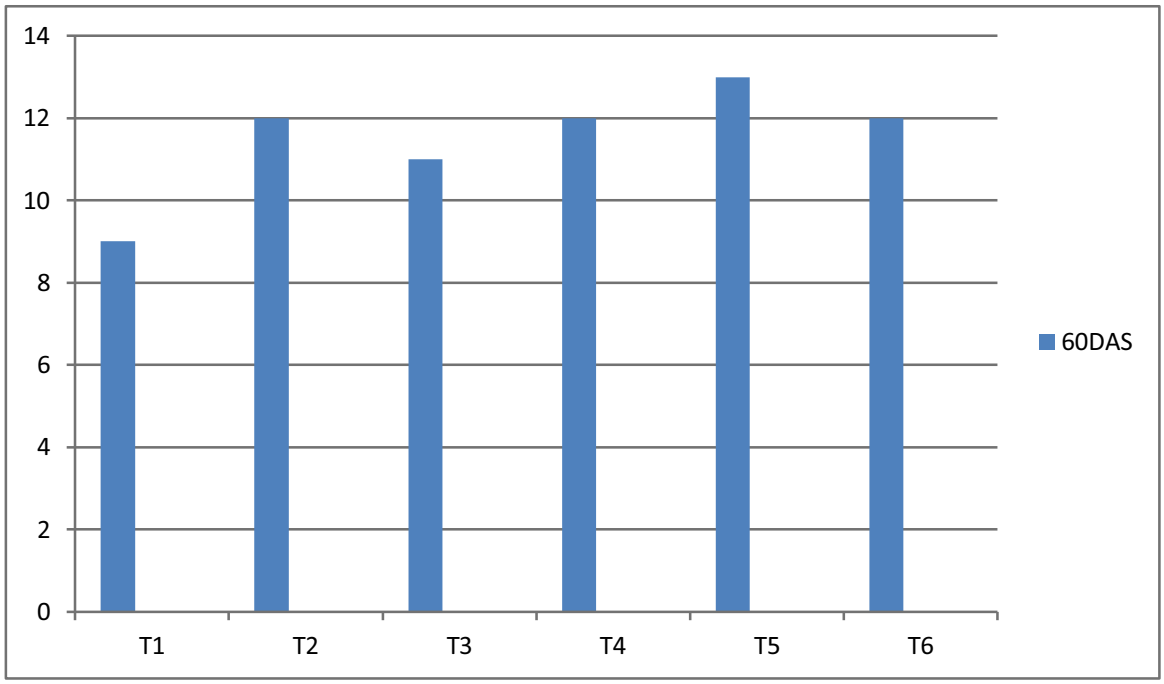
$$CGR = \frac{(W2 - W1)}{(T2 - T1)}$$

5.2.2 Number of pods per plant

It is evident from the data that foliar application of nutrient brought significant variation in pods per plant and varied from 12.15 to 15.55. A data indicated that the maximum number of pods per plant (15.55) recorded with application of Urea @ 2% + Nitrobenzene 2% + Salicylic acid @ 75ppm spray (T5) along with RDF, which was at par with RDF + Nitrobenzene @ 2% (T2), RDF + Soil application of DAP @ 2% (T3), RDF + Salicylic acid at 75 ppm spray . The lowest number of pods per plant was recorded with application of RDF + Water spray (control) (T1) (12.15). Foliar application of Urea @ 2% + Nitrobenzene 2% + Salicylic acid @ 75ppm spray, Salicylic acid @ 75ppm spray and DAP @ 2% spray along with RDF produced 27.98%, 16.46%, 11.93%, 9.63% and 6.99% higher number of pods per plant than RDF + Water spray (control)(T1) respectively.

Treatments	Nutrient Management	60 DAS
T1	RDF + Water spray	9
T2	RDF + Foliar application of nitrobenzene @ 2%	12
T3	RDF + DAP @ 2% spray	11
T4	RDF + Salicylic acid at 75ppm spray	12
T5	RDF + Nitrobenzene 2% + Urea @ 2% + Salicylic acid at 75 ppm	13
T6	RDF + 25 kg of nitrogen + DAP @ 2%	12

Table 5.4 Number of pods per plant



Graph 5.4 Observation of Pods per plant

5.2.3 Number of seeds per pod

Number of seeds per pod varied from 11.80 to 13.27 and was significantly influenced by the foliar treatment. Analysis of data revealed that the highest number of seeds per pod (13.27) was recorded with application of RDF + Urea @ 2% + Nitrobenzene 2% + Salicylic acid @ 75ppm spray (T6) which was at par with all other treatments except RDF + Water spray (control) (T1) which recorded lowest number of seeds per pod (11.80).

5.3 Yield

The data pertaining to grain yield (kg/ha), straw yield (kg/ha) and harvest index (%) as influenced by foliar application of nutrients have been presented in the data

5.3.1 Grain yield

It is observed that grain yield was varied from 400 kg/ha to 800 kg/ha and significantly influenced by foliar application. It is evident from that green gram crop fertilized with RDF along with Urea @ 2% + Nitrobenzene 2% + Salicylic acid @ 75ppm spray (T5) produced highest grain yield (800 kg/ha) and it was statistically at par with RDF + Salicylic acid at 75ppm spray at flower initiation (T4) (711kg/ha), RDF + Urea @ 2% spray (T3) (710kg/ha) and significantly superior to RDF + Foilar application of Nitrobenzene @ 2% at 45 days (T2) (614 kg/ha), and RDF + Water spray (control) (T1) (400kg/ha).

The lowest grain yield was obtained in RDF + Water spray (control) (T1) (400 kg/ha). The application of Urea @ 2% + Nitrobenzene 2% + Salicylic acid @ 75ppm spray, Nitogen + DAP @ 2%, Urea @ 2% spray, Salicylic acid @ 75ppm spray and DAP @ 2% spray increase in grain yield of green gram over RDF + Water spray (control) (T1).

5.3.3 Harvest index

It is revealed from the data on harvest index that the harvest index did not differ significantly due to different levels of foliar application. Harvest index varied from 25.21 % to 28.53 %. The highest harvest index was obtained with application of RDF + Water spray (control)(T1) (28.53 %) while the lowest harvest index was recorded with RDF + Urea @ 2% + Nitrobenzene 2% + Salicylic acid @ 75ppm spray (T5) (25.21 %)

5.4 Nitrogen uptake

5.4.1 By grain

It is observed that nitrogen uptake by grain was varied from 9.10 kg/ha to 21.32 kg/ha and significantly influenced by foliar application. Significantly maximum nitrogen uptake was recorded with application of Urea @ 2% + Nitrobenzene 2% + Salicylic acid @ 75ppm spray(T5) along with RDF (21.32 kg/ha) which was at par with all other treatments except RDF + Nitrobenzene @ 500ppm spray(T2) (9.10 kg/ha) which received lowest nitrogen uptake.

5.4.2 By plant

Data pertaining to nitrogen uptake by straw of green gram revealed that the foliar application of nutrients significantly influenced the nitrogen uptake by straw and it was varied from 6.15 kg/ha to 20.51 kg/ha. The maximum nitrogen uptake by straw (20.51 kg/ha) was recorded in RDF + 25 kg of extra dose of nitrogen spray(T6), which was significantly superior to all other treatments except RDF + Urea @ 2% spray(T2) (27.92 kg/ha). The minimum nitrogen uptake by straw (8.15 kg/ha) was found with RDF + Nitrobenzene @ 500ppm spray (T2). The application of 25kg of extra dose of nitrogen and urea @ 2% spray found higher nitrogen uptake by straw over RDF + Nitrobenzene 2% at 45 DAS.

5.4.3 Total uptake

Data pertaining to total uptake of nitrogen in green gram have been revealed that foliar application of nutrients significantly influenced the total uptake of nitrogen and it was varied from 20.25 kg/ha to 51.46 kg/ha. It is evident from the data that among different treatment of nutrition, significantly highest total

uptake of nitrogen (51.46 kg/ha) was recorded with application of 25kg of extra dose of nitrogen (T6) along with RDF which remained at par with RDF + Urea @ 2% + Nitrobenzene 2% + Salicylic acid @ 75ppm spray(T5) (67.52 kg/ha) and RDF + Salicylic acid @ 75ppm spray(T4) (41.23 kg/ha). The lowest total nitrogen uptake (20.25 kg/ha) was obtained with RDF + Nitrobenzene @ 2% spray (T2). The application of Urea @ 2% + Salicylic acid @ 75ppm spray, Urea @ 2% spray and Salicylic acid @ 75ppm spray has recorded higher uptake of total nitrogen over RDF + Nitrobenzene 2% @ 45 DAS.

5.5 Phosphorus uptake

5.5.1 By grain

Data pertaining to phosphorus uptake by grain of green gram have been revealed that the foliar application of nutrients significantly influenced the phosphorus uptake by grain and it was varied from 1.38 kg/ha to 2.57 kg/ha. Significantly maximum phosphorus uptake by grain was recorded with application of Nitogen @ 2% spray (T6) along with RDF (2.57 kg/ha), which was at par with all other treatments except RDF + Nitrobenzene @ 500ppm spray(T8) (2.38 kg/ha) and RDF + Water spray (control) (T1) (1.50 kg/ha). Minimum phosphorus uptake by grain was recorded with application of RDF + Nitrobenzene 2% (T2) (2.38 kg/ha).

5.5.2 By plant

Data pertaining to phosphorus uptake by straw of green gram have been revealed that the foliar application of nutrients significantly influenced the phosphorus uptake by straw and it was varied from 1.69 kg/ha to 3.37 kg/ha. Significantly maximum phosphorus uptake by straw (2.37kg/ha) was recorded in RDF + Urea @ 2% spray(T6), which was at par with RDF + Urea @ 2% + Salicylic acid @ 75ppm spray(T6) (3.15 kg/ha). The minimum phosphorus uptake by straw (1.69 kg/ha) was found with RDF + Salicylic acid @ 75ppm spray (T4). The application of Urea @ 2% spray and Urea @ 2% + Salicylic acid @ 75ppm spray higher phosphorus uptake by straw over RDF + Salicylic acid @ 75ppm spray.

5.5.3 Total uptake

Data pertaining to total uptake of phosphorus (kg/ha) revealed that foliar application of nutrients significantly influenced the total uptake of phosphorus and it was varied from 2.64 kg/ha to 4.60 kg/ha. It was evident from the data that among different treatment of nutrition, significantly maximum total uptake of phosphorus (4.60 kg/ha) was recorded with application of Urea @ 2% + Salicylic acid @ 75ppm spray (T5) along with RDF which remained at par with RDF + Urea @ 2% spray (T2) (6.41 kg/ha). The lowest total phosphorus uptake (4.64 kg/ha). The application of Urea @ 2% + Salicylic acid

@ 75ppm spray, Urea @ 2% spray has higher uptake of total phosphorus over RDF + Salicylic acid @ 75ppm spray.

5.6 Phosphate uptake

5.6.1 By grain

Data pertaining to potassium uptake revealed that the foliar application of nutrients, significantly influenced the total potassium uptake by grain and straw of green gram and it was varied from 5.31 kg/ha to 4.70 kg/ha. Significantly maximum potassium uptake by grain was recorded with application of Urea @ 2% + Nitrobenzene 2% + Salicylic acid @ 75ppm spray(T4) along with RDF (5.31 kg/ha), which was at par with RDF + DAP @ 2% spray(T3) (3.80 kg/ha) and RDF + Salicylic acid @ 75ppm spray(T4) (3.58 kg/ha). The lowest potassium uptake by grain was recorded with RDF + Nitrobenzene @ 500ppm spray (T8) (2.70 kg/ha). The potassium uptake by grain increased by 34.25%, 31.70%, 23.40%, 21.92%and 18.72% when crop fertilized with RDF and sprayed with Urea @ 2% + Nitrobenzene 2% + Salicylic acid @ 75ppm spray, RDF + DAP @ 2% spray and RDF + Salicylic acid @ 75ppm spray over RDF + Nitrobenzene @ 2% spray.

5.6.2 By plant

Data pertaining to potassium uptake in straw revealed that the foliar application of nutrients significantly influenced the potassium uptake by straw of green gram and it was varied from 12.59 kg/ha to 6.46 kg/ha. Significantly maximum potassium uptake by straw (12.59 kg/ha which was at par with RDF + Urea @ 2% + Nitrobenzene 2% + Salicylic acid @ 75ppm spray (T5)(11.39 kg/ha). The minimum potassium uptake by straw (6.46 kg/ha) was found with RDF + Water spray (control) (T1).The application of Urea @ 2% + Nitrobenzene 2% + Salicylic acid @ 75ppm spray has higher potassium uptake by straw over RDF + Water spray (control) (T1).

5.6.3 Total uptake

Data pertaining to total uptake of potassium (kg/ha) have been revealed that foliar application of nutrients significantly influenced the total uptake of potassium and it was varied from 12.30 kg/ha to 18.78 kg/ha. It is evident from the data that among different treatment of nutrition, maximum total uptake of potassium (18.78 kg/ha) was recorded which was found to be significantly superior over all other treatments. The lowest total potassium uptake (14.30 kg/ha) was obtained with RDF + Water spray (control)(T1). The application of DAP @ 2% spray has higher uptake of total potassium over RDF + Water spray (control).

CHAPTER 6

SUMMARY AND DISCUSSION

The present investigation entitled "Effect of foliar nutrition on productivity of green gram (Vigna radiata L.)" was conducted during kharif 2020 at the Paavai field, Namakkal. The soil was sandy loam in texture and acidic (pH-5.55) in reaction, with low to medium in soil fertility: organic carbon (2.3kg), available nitrogen (139.1 kg/ha), available phosphorous (24.7 kg/ha), available potassium (148 kg/ha). The experiment was laid out in a randomized block design with ten treatments replicated thrice. The important findings of the experiment have been summarized and concluded here under this chapter:

1. Plant height increased with the growth stages and highest values were obtained at different stages for the treatment where, RDF along with foliar application of Urea @ 2% + Nitrobenzene 2% + Salicylic acid @ 75ppm spray recorded maximum plant height at 45 DAS (28cm), 60 DAS (32cm).

2. Foliar application of Urea @ 2% + Nitrobenzene 2% + Salicylic acid @75ppm spray along with RDF produced maximum nodule number per plant (24.03) at 45DAS.

3. Dry matter production per m2 increased as the growth progressed and maximum value was obtained at harvest. RDF along with foliar application of Urea @ 2% + Nitrobenzene 2% + Salicylic acid @75ppm spray recorded highest dry matter accumulation at 45 DAS (74.14 g/m2), 60 DAS (188.55 g/m2) and at harvest (206.70 g/m2).

4. Leaf area index increased with the progress in growth and maximum value was obtained at 60 DAS. Urea @ 2% + Nitrobenzene 2% + Salicylic acid @75ppm spray along with RDF recorded maximum leaf area index (4.00) at 60 DAS.

5. The foliar application of Urea @ 2% + Nitrobenzene 2% + Salicylic acid @75ppm spray along with RDF produced maximum number of branches per plant (5.07) at harvest.

6. Crop growth rate (CGR) of green gram was recorded maximum at 45-60 DAS and thereafter it declined. Urea @ 2% + Nitrobenzene 2% + Salicylic acid @75ppm spray along with RDF recorded highest CGR at 30-45 DAS (2.87 g/m2/day), 45-60 DAS (5.37 g/m2/day) and at 60 DAS-harvest (3.65 g/m2/day).

7. Among different treatments, higher number of pods per plant (15.55), seeds per pod (13.27) and 100 seed weight (3.47 g) was recorded with Urea @ 2% + Nitrobenzene 2% + Salicylic acid @ 75ppm spray along with RDF.

8. Application of Urea @ 2% + Nitrobenzene 2% + Salicylic acid @ 75ppm spray along with RDF recorded higher grain (800 kg/ha) and straw yield (1000 kg/ha).

9. Protein content was recorded maximum (26.40 %) with salicylic acid @75ppm spray along with RDF, although there was no significant difference among the treatments.

10. Total uptake of N (21.46 kg/ha) and K (18.78 kg/ha) was recorded maximum with application of 20:50:0 (N:P:K) @ 2% spray along with RDF and P (6.60 kg/ha) total uptake with Urea @ 2% + Nitrobenzene 2% + Salicylic acid @75ppm spray along with RDF.

CHAPTER 7

CONCLUSIONS

On the basis of one year experimentation, following conclusions can be drawn:

1. Foliar application of Urea @ 2% + Nitrobenzene 2% + Salicylic acid @75ppm spray along with RDF produced higher growth, yield attributes, grain yield as well as straw yield of green gram.

2. Foliar application of Urea @ 2% + Nitrobenzene 2% + Salicylic acid @75ppm spray along with RDF to green gram crop led to better utilization of nutrient as it favoured highest uptake of nitrogen (N), phosphorus (P) and by grain as by straw.

3. Foliar application of Urea @ 2% + Nitrobenzene 2% + Salicylic acid @75ppm spray along with RDF to green gram crop was found advantageous as it produced highest net return and benefit cost ratio making it economically viable for the farmers.

Based on the result of present investigation, it may be concluded that foliar application of Urea @ 2% + Nitrobenzene 2% + Salicylic acid @75ppm spray along with RDF proved to be more productive and economically viable for green gram cultivation.

ABSTRACT

Now a day, during the summer seasons the cultivated crops gets affected due to the heavy sunshine intensity and temperature. The main theme of this project is that to prevent the crops from the heavy sunshine, temperature, warmth and then save crops. The Temperature sensor and Humidity sensor is used for the working of automatic roof and control the environment condition. This system involves protects the crops by the auto roof which covers the greenhouse. Temperature sensor is used to measure sunshine intensity, temperature value from outer site of greenhouse. When to reached high temperature value, this system is automatically closed roof in greenhouse for reducing impact of high sunshine intensity. Humidity sensor is used to measure temperature value of innerside of greenhouse during high sunshine intensity season like April and May and ventilation fan and water sprayer is used to reducing temperature and to maintain favourable environment condition in greenhouse.

Our project can be considered as the central issue in designing portable greenhouse. This technology provides the portable roof with temperature sensor which it can use to measure temperature of outside in greenhouse and then control the roof condition (open or close) and humidity sensor can use to measure the humidity and temperature of inside greenhouse and then control ventilation fan and water spraying system . It is a portable greenhouse system that works on Arduino Microcontroller and employs two sensors to measure temperature and humidity condition. The Arduino board was selected as the microcontroller platform and its software counterpart, Arduino Software, was used to carry out the programming

Keyword: *Temperature and Humidity sensor, Arduino microcontroller, greenhouse, Arduino software.*

CHAPTER I

INTRODUCTION

1.1. GENERAL

The framework depends on Arduino microcontroller, programmed work, Ultrasonic sensor, Temperature sensor and Humidity sensor. This framework utilizes battery-powered force putting away sources as 12V battery that is energized from AC current. At that point AC current is put away in 12V DC battery. During summer season, part of harvests are high influenced by substantial daylight, temperature and warmth. Primary goal of our venture is to keep crops from high daylight force, temperature and warmth during summer season and make positive condition are keep up consequently.

Temperature sensor is utilized to gauge daylight power, warmth and temperature esteem from external site of nursery. When to arrive at high warmth and temperature esteem, this framework is consequently shut rooftop in nursery for lessening effect of high daylight force. Dampness sensor is utilized to gauge temperature estimation of within nursery during high daylight force season like April and May and ventilation fan and water sprayer is utilized to evacuate heat and to keep up ideal condition in nursery. Ultrasonic sensor is put front of the nursery rooftop. It is utilized to distinguish any specialist or human will enter the nursery and consequently open and close the entryway framework. Fundamental point of our task is make full and full programmed nursery framework for decreasing human work adequacy, working time and any wastage of vitality or force.

This device consists of temperature sensor, Arduino-Uno, motors and bio-degradable plastic materials for shade. When the high temperature is detected by the sensor it gives signal to Arduino-Uno. Further Arduino gives signal to the motor due to which the roof gets over the crops and protect crops from being destroyed. And when the reducing temperature ranges stops the roof automatically opens. This device is simple but

very useful for farmers to save their money which they have invested and their time. And above all it runs on the solar energy making it more cost effective and eco-friendly.

When inside of greenhouse have a high temperature during roof closed condition of greenhouse. The Humidity sensor is used to measure humidity and temperature of inside greenhouse and detect high heat condition gives signal to Arduino–UNO. Further Arduino gives signal to the water pump and ventilation fan due to which ventilation fan is used to reducing heat and pump is used to spray the water to crop for reducing heat.

1.2. OBJECTIVES

- To prevent crops and plants from the high sunshine intensity, warmth and temperature.
- To make favourable environment condition for plats growth.
- To control sunshine intensity, heat and temperature inside the greenhouse.

CHAPTER 2

LITERATURE REVIEW

***S.RAJESH, CHANG LEE AND G.SHARWESH*(2019)** entitled **"AUTOMATIC SMART ROOF SYSTEM USING ARDUINO AND RAIN DROP SENSOR"** said**,** This project deals with a when unseasonal rain falls on the harvested crops, which are kept to dried up, they rot up and get destroyed due to which farmers have to face enigma. Some crops must be dried before it is sold to the agriculture market yard, so the farmer needs some space for the crops to dry which most of the farmers don't have and it take loads of time to dry up. As the farmers have invested their time almost three to four months and huge amount of capital both, in the yield and as it gets ruined by rainfall, farmer's assets and time goes in vain. So as farmer's faces loss, this device is built up to protect them from severe loss. This device is used in agriculture purpose in a way when the rain drops falls on the rain sensor, the roof automatically gets over the crops kept for drying. This device consists of rain sensor, Arduino-Uno, motors and bio-degradable plastic materials for shade. When the rain is detected by the sensor it gives signal to Arduino-Uno. Further Arduino gives signal to the motor due to which the roof gets over the crops and protect crops from being destroyed. And when the rainfall stops the roof automatically opens. This device is simple but very useful for farmers to save their money which they have invested and their time. And above all it runs on the solar energy making it more cost effective and eco-friendly.

In Our project are working same principle but replacing the rain sensor to temperature sensor for detect high temperature ranges.

R.BALATHANDAPANI, D.BOOPATHI, S.JOTHEESHWARAN, G.ARUNDEVA **(2018)** entitled **"TEMPERATURE BASED SPEED CONTROL OF FAN USING ARDUINO"** said, In present scenario, availability of electricity is found to reach crucial stage. To protect and safeguard one's future we need to save the energy. As a slogan suggest "One unit saved is one unit generated". The project is a standalone automatic fan speed controller that controls the speed of an electric fan according to our requirement. Use of embedded technology makes this closed loop feedback control system efficient and reliable. Arduino microcontroller allows dynamic and faster control. Liquid crystal display (LCD) makes the system user friendly. The sensed temperature and fan speed level values are simultaneously displayed on the LCD panel. It is very compact as it is constructed by using few components and can be interfaced for several applications including air-conditioners, water-heaters, snow-melters, ovens, heat-exchangers, mixers, furnaces, incubators, thermal baths and veterinary operating tables. Arduino micro controller is the heart of the circuit as it controls all the functions. The temperature sensor LM35 senses the temperature and converts it into an electrical signal, which is forwarded to the microcontroller. The sensed and set values of the temperature are displayed on the 16x2-line LCD. The microcontroller drives Transistor to control the fan speed. This project uses regulated 12V, 2A power supply. This project is useful in process industries for maintenance and controlling of Boilers temperature.

In our project, we follow same principle of this projects but we are using some different methods for reducing heat in greenhouse by using ventilation fan system.

PROF. ABHIJIT G KALBANDE **(2018)** Entitled " **SMART AUTOMATION SYSTEM USING ARDUINO AND RAIN DROP SENSOR"** said, In this paper we present Idea related to agricultural based system in which as per our observation during the rainy seasons the cultivated crops gets affected due to the heavy rain fall. The main theme of this project which is presented in the paper is that to prevent the crops from the

heavy rain and save the rain water. The raindrop sensor and soil moisture sensor is used for the working of automatic roof. This system involves protects the crops by the auto roof which covers the whole field. The rain sensor is activated when there is a rain fall. The soil moisture sensor will sense the water level in the field. If the water level is beyond the normal level it will gives intimation to the controller. So when both the sensor is 'ON', it will gives intimation to the controller, GSM and it will indicate to the DC motor and it will automatically open the roof. In this project, the roof is open automatically when both the sensor is 'ON'. This complete system can be handled manually If there is any problem with opening the roof automatically, it is blend idea with controlling operation done through Arduino. GSM is report the conditions in the field through SMS to the mobile phone. The power is supplied to this project is using renewable energy sources as solar power. Direct power supply can also be fabricated which affect the basic cost to build entire system.

In our project, we follow same operation and working principle of this projects but we are replace raindrop sensor to temperature sensor and its connected to Arduino board.

***T.RAMMOHAN, ALISTER VARGHESE, S.DINESH BABU, N. JAYASAKTHIRAM, D.JAGADEESHWARAN*(2017)** entitled **"DESIGN AND DEVELOPMENT OF AUTOMATIC RETRACTABLE ROOF FOR CLOTHESLINE WITH NOTIFICATION SYSTEM "** said, Nowadays because of corporate culture people spend less time at house, and some require the help of latest technologies for safety and other basic needs. Smart home automation gadgets are created to minimize these problems. Main theme of this project is to prevent washed clothes becoming wet by rain while hanged in clothesline. This problem occurs when the user is not at reachable area when the rain occurs. A retractable roof which senses rainy condition and covers the clothes line from rain. Thus, the proposed hardware contains three modules sensing, driving, notification systems. Sensing and driving modules are controlled by

Arduino UNO controller. Notification system comprises of user's login details and status of the retractable roof. As in many retractable roof the driving mechanism is by a tubular motor. Tubular motor works in servo mechanism, hence in this prototype servo motor is used for driving module. And this proposed method is more simple in design and low cost to construct than its previous versions. In our project, we are using this technology only for greenhouse system. When high temperature occurring period are detect by using temperature sensor and give signal to Arduino UNO board and Arduino is control the greenhouse roofing system.

AZAHAR W SHAIKH AND SOMESH A INGOLE **(2017)** entitled**"PROTECTION OF VEHICLES AND CROPS FROM AUTOMATIC ROOFING AUTOMATION SYSTEM"** said, Now a days in the rainy season vehicles get affected due to rainfall. The main aim of this project is that to protect vehicles from heavy rain. Rain sensing module is used for working of auto roof . Rain sensing module activated when there is rain fall, it will give input to the controller and GSM then DC motor rotate to get cover on the vehicle. In this project roof is automatically open when sensor is 'ON' also it will be automatically closed when rain is stopped. The power supply is supplied to this project is using renewable energy sources as solar power. Direct power supply can also be fabricated but which affect the cost of system.

In our project, we are follow same working principle but to protect crops from high temperature during summer season by using automated greenhouse roofing system.

P. GOUTHAM GOUD, N. SURESH, Dr. E. SURENDHAR, G. GOUTHAM, V. MADHU KIRAN. **(2016)** entitled **"RAIN SENSOR AUTOMATICALLY CONTROLLED DRYING SHED FOR CROP YIELD FARMERS"** said, Now a day's technology is running with time, it completely occupied the life style of human beings. Even though there is such an importance for technology in our routine life there are even

people whose life styles are very far to this well-known term technology. So it is our responsibility to design few reliable systems which can be even efficiently used by them, farmers. The farmer who toil and does hard work to produce the crop suffers a lot at the end. The factors include unexpected rains when yielded crop is dried before selling, which will completely destroy the crop yield or make the yield second grade. To avoid such condition, automatic rain protected drying sheds are to be developed. In this project, we propose a system in which the rains are detected automatically and protective shield is wrapped on the rooftop sensor an intelligent microcontroller and a DC motor are employed. The rain sensor of such drying shed which protect the crop against rain and getting wet. To automate this task, a rain senses the rain and data is passed to the microcontroller. The microcontroller processes the data and activates the DC motor control circuit and a protective wrapper is wrapped on the roof top.

In our project, we follow same operation and working principle of this projects but we are replace raindrop sensor to temperature sensor and its connected to Arduino board and its control the greenhouse roofing system during summer season.

NAVEEN K B, NAVEEN KUMAR S K, PURUSHOTHAM M D, SAGAR G H, YOGESH M N (2016) entitled **"AUTOMATIC RAIN WATER AND CROP SAVING SYSTEM"** said, Agriculture is a backbone of our country. About almost of our country's revenue comes from agriculture. But during heavy rain falls, the farmers face lot of problems because there cultivated crops get washed off or destroyed. So in order to avoid this problem this project is designed which helps if saving the crops from heavy rainfall and protecting that rain water to use it for other purposes. The saved and stored water can be used for feeding animals, washing, cooking etc. and can also be reused to sprinkle it back to the field when needed. In this system an automatic roof is inculcated which works by taking the signals from the rain and soil moisture sensors and covers the whole field protect it from heavy rains. Whenever there is rainfall the rain sensor gets activated. Then

the controller indicates the stepper motor to run which opens the roof automatically to close and cover overall the field using a polythene sheet by based on temperature. Which is implemented is "Automated irrigation system with partition facility for effective irrigation of small scale farms" (AISPF). But this method has some drawbacks which can be improved and here we are with a method called "Automated irrigation system using weather prediction for efficient usage of water resources" (AISWP).

In our project, we follow same operation and working principle of this projects but we are replace raindrop sensor to temperature sensor and its connected to Arduino board and its control the greenhouse roofing system during summer season.

VEDASHREE.S, K.. NEERESH KUMAR, SMITHA.M, THIPPESH.D.R, KUMUDA.B, ZOYA PARVEZ, DEEPA .B (2016) entitled"**PROTECTION OF CROPS AND PROPER USAGE OF RAIN WATER WITH EMBEDDED SYSTEM USING GSM TECHNOLOGY"** said, The main theme of our project is during heavy rain falls, the farmers face lot of problems because there cultivated crops get washed off or destroyed. So in order to avoid this problem this project is designed which helps if protecting the crops from heavy rainfall and saving that rain water to use it for other purposes. The saved water can be used for feeding animals, washing, cooking etc. and can also be reused to sprinkle it back to the field when needed. In this system an automatic roof is inculcated which works by taking the signals from the rain and soil moisture sensors and covers the whole field to protect it from heavy rains. Whenever there is rainfall the rain sensor gets activated. The water level in the soil is sensed by the soil moisture sensor. Whenever there is rain, the rain sensor is „ON" and when the water level in the soil is beyond the normal level then soil moisture sensor is „ON". If both the sensors are „ON" then this information is given to the controller and the GSM. Then the controller indicates the DC motor to run which opens the roof automatically to close the field using a polythene sheet. If there is any problem in opening of the roof, then this is

intimated to the farmers thought SMS to their mobile phone using GSM. Then the roof can be opened manually using mechanical roller. In this project, the roof is open automatically when both the sensor is „ON". The emerging applications of GSM is used in this system. The power source to this project is supplied through solar power which is a renewable energy.

In our project, we follow same operation and working principle of this projects but we are replace raindrop sensor to temperature sensor and its connected to Arduino board and its control the greenhouse roofing system during summer season.

MD. NIAMUL HASSAN, AHMAD SHAMS NOOR (2015) entitled **"AN AUTOMATIC MONITORING AND CONTROL SYSTEM INSIDE GREENHOUSE"** said, In this work, we have proposed a framework that can gather the data identified with greenhouse environment and yield status and control the system automatically in view of the gathered data. By throatily observing periodic conditions, this study has the reason for securing connection between sensors flags and reference estimations. Control programming will give information finding of ongoing show. Through long time running and functional utilizing, the framework has been demonstrated that it has numerous points of interest. To monitor the environment inside greenhouse different parameters have been considered such as light, temperature, humidity, soil moisture etc. using different sensors like DHT22 temperature and humidity Sensor, LDR, grove-moisture sensor etc. which will be interfaced with microcontroller. It is a closed loop system that will execute control action to adjust temperature, humidity, light intensity and soil moisture if any unwanted errors (high/low) occur.

In our project, we are only monitoring Humidity and Temperature ranges for control environment condition in greenhouse for make a favorable condition of plant growth

RUPAM S. ROTE1AND RUPALI R. JAGTAP **(2014)** entitled **"AUTOMATIC VENTILATION CONTROL SYSTEM FOR ENERGY EFFICIENT BUILDINGS USING CO_2 SENSORS "** said, In this paper, the proposed work states automatic control strategy for ventilation systems in energy-efficient buildings. To maintain indoor CO_2 in the comfort zone to the accurate level and minimum ventilation rate is the main design goal of automatic ventilation controller. The system uses CO_2 as the main indicator of human comfort. The intelligent system as compared to traditional ON/OFF or fixed ventilation system gives better results in energy saving and also provide high indoor air quality. Through long time running and functional utilizing, the framework has been demonstrated that it has numerous points of interest. To monitor the environment inside greenhouse different parameters have been considered such as light, temperature, humidity, soil moisture etc. using different sensors like DHT22 temperature and humidity Sensor, LDR, grove-moisture sensor etc. which will be interfaced with microcontroller. It is a closed loop system that will execute control action to adjust temperature, humidity, light intensity and soil moisture if any unwanted errors (high/low) occur. The technical notes provide the block diagram description and the importance using AVR Microcontroller.

In our project, we are follow same principle but replacing CO_2 sensor and AVR microcontroller into Humidity sensor and Arduino UNO.

ASLINDA HASSAN, SIAG BING SHENG (2013) entitled **"AN AUTOMATED IRRIGATION SYSTEM USING ARDUINO MICROCONTROLLER"** said, An Automated Irrigation System Using Arduino Microcontroller" by Aslinda et al. proposes an automated irrigation using Arduino microcontroller system which is cost effective and can be used farm field or average home garden. The proposed system is developed to automatically water the plants when the soil moisture sensor has detected the soil is insufficient of water by using the Arduino as the center core. The automated irrigation system is a fully functional prototype which consists of a soil moisture sensor; an LCD display to show the moisture

percentage and pump status; a relay module which used to control the on and off switch of the water pump; and a water pump. When the soil moisture sensor sense the dry soil, it will show the moisture percentage on the LCD display, and the relay module will switch on the water pump automatically to start the watering process, or vice versa. Hardware testing is conducted to ensure the proposed system is fully functional.

In our project, We are follow same operation but not applying irrigation, only spraying of water by using pump for reducing heat in greenhouse.

P. GOUTHAM GOUD, N. SURESH, Dr. E. SURENDHAR (2007) entitled **"RAIN SENSOR AUTOMATICALLY CONTROLLED DRYING SHED FOR CROP YIELD FARMERS "** said, In this project, we propose a system in which the rains are detected automatically and protective shield is wrapped on the rooftop sensor an intelligent microcontroller and a DC motor are employed. The rain sensor of such drying shed which protect the crop against rain and getting wet. To automate this task, a rain senses the rain and data is passed to the microcontroller. The microcontroller processes the data and activates the DC motor control circuit and a protective wrapper is wrapped on the roof top. The Automatic Crop protection has been achieved successfully using microcontroller unit. The circuit has been tested and verified. We Developed Automatic crop protection shed programmed by using the microcontroller. The program has been successfully tested and verified for several specified conditions. The switching mechanism can be done automatically with the help of microcontroller using D.C motor. By using this project we can protect thousands of hectares of land from unseasonal rain. We can also increase the rate of production of crops by which we can improve the economical standards of farmers and as production increases the cost of the crop decreases for the users.

In our project, we follow same operation and working principle of this projects but we are replace raindrop sensor to temperature sensor and its connected to Arduino board and its control the greenhouse roofing system during summer season.

CHAPTER 3

METHODOLOGY

3.1. BLOCK DIAGRAM

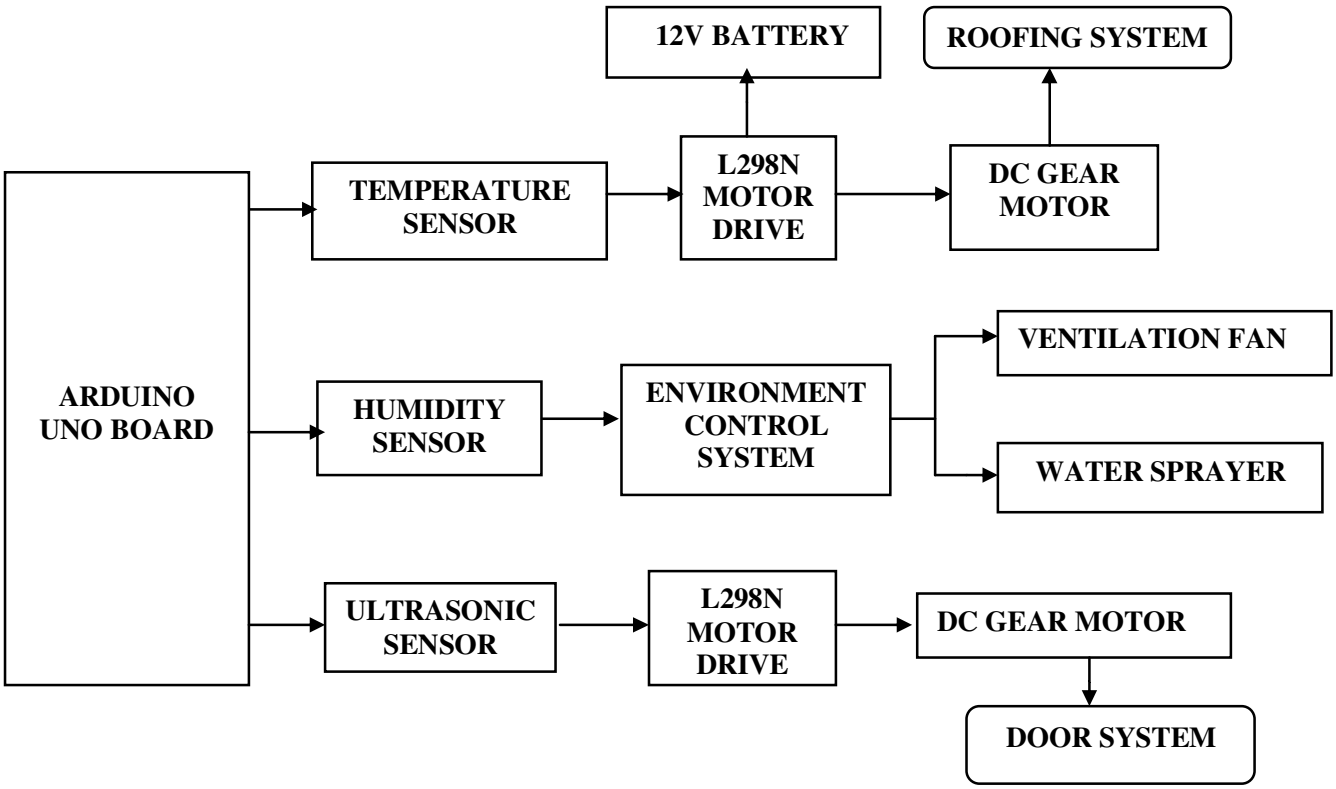

Fig. 3.1 Block diagram of AGRS

When Greenhouse contains lot of components for automatic roofing system and control the environment condition inside the greenhouse. Initially Roofing system is connected to DC Gear motor and is connected to Arduino-UNO board. When Arduino board is connected to two types of sensor such as Temperature sensor and another one is Humidity sensor. Temperature sensor is connected to roofing system and then Humidity sensor is connected to environment control system like parallel series connection of ventilation fan and submerged pump.

3.2. METHODOLOGY

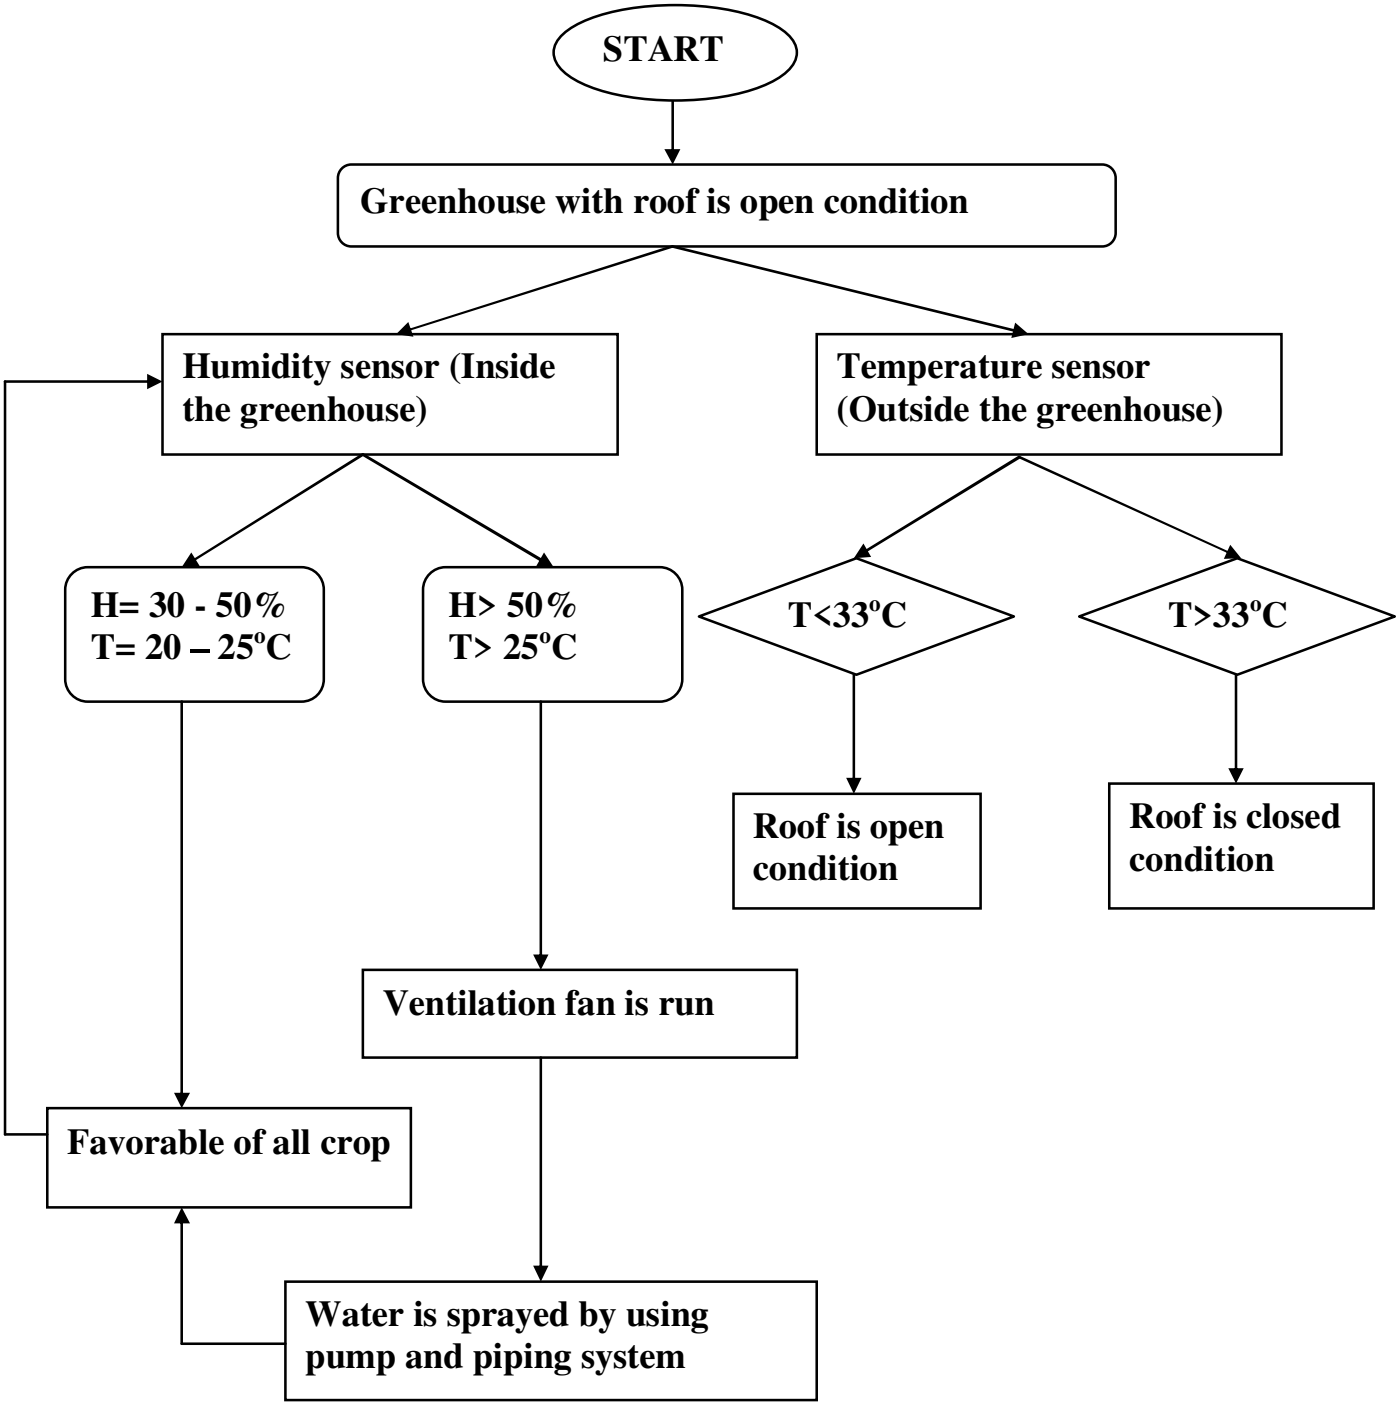

Fig.3.2 Flow chart of Methodology of AGRS

3.2.1. START: To give power of all components and check all components are worked well condition.

3.2.2. GREENHOUSE ROOF IS OPEN CONDITION: Initially greenhouse roof is always maintained open condition.

3.2.3. TEMPERATURE SENSOR: Temperature sensor is measured temperature range in outside greenhouse and signals are send to Arduino UNO.

3.2.4. T<33^{o}C: When a temperature range in outside greenhouse are less than 33^{o}C , maintained roof is open condition.

3.2.5. T>33^{o}C: When a temperature range in outside greenhouse are more than 33^{o}C , greenhouse roof are automatically closed.

3.2.6. HUMIDITY SENSOR: Humidity sensor is measured humidity and temperature range in inside greenhouse and signals are send to Arduino UNO.

3.2.7. H= 30 to 50 % and T< 25^{o}C: Favorable to all crops.

3.2.8. H>50% and T>25^{o}C: When ventilation fan is automatically ON for removing heat from inside the greenhouse and automatically water are sprayed by using pump for maintaining crops are wet condition and again to check humidity and temperature range in greenhouse..

CHAPTER 4

MATERIAL REQUIREMENT AND THEIR PROPERTIES

4.1. HARDWARE REQUIREMENT

- Arduino-UNO.
- Temperature sensor.
- Motor drive.
- Ultrasonic sensor.
- Servo motor.
- Dc gear motor.
- 16x2 LCD Display
- Submerged pump.
- Humidity sensor.
- Jumper wires.
- Ventilation fan.
- Polythene sheet.
- 12V battery.

4.2. SOFTWARE REQUIREMENT

- Arduino IDE.

HARDWARE ANALYSIS

4.1.1. ARDUINO - UNO

The Arduino UNO is an open-source microcontroller board based on the MicrochipATmega328P microcontroller and developed by Arduino. The board is equipped with sets of digital and analog input/output (I/O) pins that may be interfaced to various expansion boards (shields) and other circuits. The board has 14 Digital pins, 6 Analog pins, and programmable with the Arduino IDE (Integrated Development Environment) via a type B USB cable. It can be powered by the USB cable or by an external 9-voltbattery, though it accepts voltages between 7 and 20 volts. It is also similar to the Arduino Nano and Leonardo.

- Microcontroller: Microchip AT mega328P.
- Operating Voltage: 5Volts.
- Input Voltage: 7 to 20Volts.
- Digital I/O Pins: 14 (of which 6 provide PWM output).
- Analog Input Pins: 6.
- DC Current per I/O Pin: 20mA.
- DC Current for 3.3V Pin: 50mA.
- Flash Memory: 32 KB of which 0.5 KB used by boot loader.

Fig.4.1 Arduino UNO board

4.1.2. HUMIDITY SENSOR

A humidity sensor senses, measures and regularly reports the relative humidity in the air. It measures both moisture and air temperature. Relative humidity, expressed as a percent, is the ratio of actual moisture in the air to the highest amount of moisture air at that temperature can hold. The warmer the air is, the more moisture it can hold, so relative humidity changes with fluctuations in temperature.

Fig.4.2 Humidity sensor

Humidity sensors detect the relative humidity of the immediate environments in which They are placed. They measure both the moisture and temperature in the air and express relative humidity as a percentage of the ratio of moisture in the air to the maximum amount

that can be held in the air at the current temperature. As air becomes hotter, it holds more moisture, so the relative humidity changes with the temperature. Most humidity sensors use capacitive measurement to determine the amount of moisture in the air. This type of measurement relies on two electrical conductors with a non-conductive polymer film laying between them to create an electrical field between them. Moisture from the air collects on the film and causes changes in the voltage levels between the two plates. This change is then converted into a digital measurement of the air's relative humidity after taking the air temperature into account.

4.1.3. TEMPERATURE SENSOR

The DS18B20 Stainless Steel Temperature Sensor is a pre-wired and waterproofed version of the DS18B20 sensor. Its unique 1-wire interface makes it easy to communicate with devices. It can converts temperature to a 12-bit digital word in 750ms(max). Besides, it can measures temperatures from -55°C to +125°C (-67F to +257F). In addition, this thermo probe doesn't require any external power supply since it draws power from data line. Its stainless steel probe head makes it suitable for any wet or harsh environment. The working principle of DS18B20 Stainless Steel Temperature Sensor and DS18B20 Temperature Sensor is same but the only difference is that the temperature sensor is placed inside the stainless steel probe.

- Power supply range: 3.0V to 5.5V
- Operating temperature range:-55°C to +125°C (-67F to +257F)
- Temperature-limit alarm system
- ±0.5°C Accuracy from -10°C to +85°C
- 9 to 12 bit selectable resolution
- Uses 1-Wire interface- requires only one digital pin for communication

Fig.4.3 Temperature sensor

4.1.4. MOTOR DRIVE MODULE:

The L298N H-bridge module can be used with motors that have a voltage of between 5 and 35v dc. With the module used in this tutorial, there is also an onboard 5V regulator, so if your supply voltage is up to 12V you can also source 5V from the board.

Fig.4.4 L298N Motor drive

- 2 connections for 5V 'hobby' servos connected to the Arduino's high-resolution dedicated timer – no jitter!

- Up to 4 bi-directional DC motors with individual 8-bit speed selection (so, about 0.5%resolution).
- Up to 2 stepper motors (unipolar or bipolar) with single coil, double coil, interleaved or micro-stepping.
- 4 H-Bridges: L293D chipset provides 0.6A per bridge (1.2A peak) with thermal shutdown protection, 4.5V to25V.
- Pull down resistors keep motors disabled during power-up.
- 2-pin terminal block to connect external power, for seperate logic/motor supplies.

4.1.5. SUBMERSIBLE PUMP

A submersible pump (or sub pump, electric submersible pump (ESP)) is a device which has a hermetically sealed motor close-coupled to the pump body. The whole assembly is submerged in the fluid to be pumped. The main advantage of this type of pump is that it prevents pump cavitation's, a problem associated with a high elevation difference between pump and the fluid surfaces. Submersible pumps push fluid to the surface as opposed to jet pumps which create a vacuum and rely upon atmospheric pressure. Submersibles are more efficient than jet pumps. Hydraulic submersible pumps (HSP's) use pressurized fluid from the surface to drive a hydraulic motor down hole, rather than an electric motor, and are used in heavy oil applications with heated water as the motive fluid.

Electric submersible pumps are multistage centrifugal pumps operating in a vertical position. Liquids, accelerated by the impeller, lose their kinetic energy in the diffuser where a conversion of kinetic to pressure energy takes place. This is the main operational mechanism of radial and mixed flow pumps. In the HSP, the motor is a hydraulic motor rather than an electrical motor, and may be closed cycle (keeping the power fluid separate from the produced fluid) or open cycle (mingling the power fluid with produced fluid down hole, with surface separation). The pump shaft is connected to the gas separator or the protector by a mechanical

coupling at the bottom of the pump. Fluids enter the pump through an intake screen and are lifted by the pump stages. There are also screw-type submersible pumps, there is a steel screw which is used as a working element in them. The screw allows the pump to work in water with a high sand content and other mechanical impurities.

Fig.4.5 Submersible pump

4.1.6. 16x2 LCD DISPLAY:

LCD (Liquid Crystal Display) screen is an electronic display module and find a wide range of applications. A 16x2 LCD display is very basic module and is very commonly used in various devices and circuits. A 16x2 LCD means it can display 16 characters per line and there are 2 such lines. In this LCD each character is displayed in 5x7 pixel matrix. This LCD has two registers, namely, Command and Data.

Fig.4.6 16x2 LCD Display

4.1.7. POLYETHENE SHEET(FILM)

Polyethylene or polythene (abbreviated PE; IUPAC name polyethene or poly (methylene)) is the most common plastic. As of 2017, over 100 million tones of polyethylene resins are produced annually, accounting for 34% of the total plastics market. Its primary use is in packaging (plastic bags, plastic films, geomembranes, containers including bottles, etc.). Many kinds of polyethylene are known, with most having the chemical formula (C2H4)n. PE is usually a mixture of similar polymers of ethylene with various values of n. Polyethylene is a thermoplastic; however, it can become a thermo set plastic when modified (such as cross-linked polyethylene).

Fig.4.7 Polyethene sheet(film)

4.1.8. VENTILATION (EXHAUST) FAN

Fig.4.8 Ventilation fan

A Exhaust fan is any fan inside, or attached to, a building or greenhouse base used for active cooling. Fans are used to draw cooler air into the case from the outside, expel warm air from inside and move air across a heat sink to cool a particular component. Both axial and sometimes centrifugal (blower/squirrel-cage) fans are used in computers. Computer fans commonly come in standard sizes, and are powered and controlled using 3-pin or 4-pin fan connectors.

While in earlier house, kitchen, building, industries and greenhouse it was possible to cool most components using natural convection (passive cooling), many modern components require more effective active cooling. To cool these components, fans are used to move heated air away from the components and draw cooler air over them. Fans attached to components are usually used in combination with a heat sink to increase the area of heated surface in contact with the air, thereby improving the efficiency of cooling. Fan control is not always an automatically.

4.1.9. ULTRASONIC SENSOR

The ultrasonic sensor consists of a multi vibrator, which fixed at its base. The multi vibrator is combination of a resonator and vibrator. The ultrasonic waves generated by the vibration are delivers to the resonator. Ultrasonic sensor actually consists of two parts: the emitter which produces a 40 kHz sound wave and detector which detects 40 kHz sound wave and sends electrical signal back to the microcontroller. In our project, we are using HC-SR04 ultrasonic sensors which consist of 4 pins VCC, Trigger, Echo and GND.

- Effectual Angle: <15degree
- Ranging Distance: 2cm – 400cm
- Resolution: 0.3cm
- Measuring Angle: 30 degree

Fig.4.9 Ultrasonic sensor

4.1.10. SERVO MOTOR

Servomotors are used in applications such as robotics, CNC machinery or automated manufacturing. The Tower Pro SG90 is a simple Servo Motor which can rotate 90 degrees in each direction (approximately 180 degrees in total). The servo motor consists of three wires.

i. Yellow wire – Control
ii. Red wire - +5 V
iii. Black wire – Ground

Fig.4.10 Servo Motor

4.1.11. DC GEAR MOTOR

Fig.4.11 DC gear motor

A DC motor is any of a class of rotary electrical machines that converts direct current electrical energy into mechanical energy. The most common types rely on the forces produced by magnetic fields. Nearly all types of DC motors have some internal mechanism, either electromechanical or electronic, to periodically change the direction of current flow in part of the motor. . A DC motor's speed can be controlled over a wide range, using either a variable supply voltage or by changing the strength of current in its field windings. Small DC motors are used in tools, toys, and appliances. The universal motor can operate on direct current but is a lightweight brushed motor used for portable power tools and appliances.

SOFTWARE ANALYSIS

4.2.1. ARDUINO IDE

The Arduino integrated development environment (IDE) is a cross-platform application (for Windows, Mac OS, Linux) that is written in the programming language Java. It is used to write and upload programs to Arduino compatible boards, but also, with the help of 3rd party cores, other vendor development boards. The source code for the IDE is released under the GNU General Public License, version 2.The Arduino IDE supports the languages C and C++ using special rules of code structuring. The Arduino IDE supplies a software library from the Wiring project, which provides many common input and output procedures. User-written code only requires two basic functions, for starting the sketch and the main program loop, that are compiled and linked with a program stub *main()* into an executable cyclic executive program with the GNU tool chain, also include with the IDE distribution. The Arduino IDE employs the program *avrdude*to convert the executable code into a text file in hexadecimal encoding that is loaded into the Arduino board by a loader program in the board's firmware.

4.2.2.PROPERTIES OF ARDUINOIDE

- Arduino IDE is an open source software that is mainly used for writing and compiling the code into the Arduino Module.
- It is an official Arduino software, making code compilation too easy that even a common person with no prior technical knowledge can get their feet wet with the learning process.
- It is easily available for operating systems like MAC, Windows, Linux and runs on the Java Platform that comes with inbuilt functions and commands that play a vital role for debugging, editing and compiling the code in the environment.
- A range of Arduino modules available including Arduino Uno, Arduino Mega, Arduino Leonardo, Arduino Micro and many more.
- Each of them contains a microcontroller on the board that is actually programmed and accepts the information in the form of code.
- The main code, also known as a sketch, created on the IDE platform will ultimately generate a Hex File which is then transferred and uploaded in the controller on the board.
- The IDE environment mainly contains two basic parts: Editor and Compiler where former is used for writing the required code and later is used for compiling and uploading the code into the given Arduino Module.
- This environment supports both C and C++languages.
- It is easily available for operating systems like MAC, Windows, Linux and runs on the Java Platform that comes with inbuilt functions and commands that play a vital role for debugging, editing and compiling the code in the environment.
- Each of them contains a microcontroller on the board that is actually programmed and accepts the information in the form of code

CHAPTER 6

ALGORITHM AND PROGRAMMES

6.1. ALGORITHM:

1. Start

2. Check roof is open or closed condition.

3. Measure temperature range.

4. T<28^{o}C to maintain roof is open condition.

5. T>28^{o}C to closed roof until reducing temperature range.

6. Measure humidity range in greenhouse.

7. H= 30 – 50 % , this condition don't run any components.

8. H>50 % , this condition to run ventilation fan and water sprayer.

9. Then again to check step 6.

6.2. PROGRAMME

```
#include <DallasTemperature.h>
#include <Stepper.h>
#include <OneWire.h>
#include <dht.h>
const int stepsPerRevolution = 200;
Stepper myStepper(stepsPerRevolution, 8, 9, 10, 11);
#define ONE_WIRE_BUS 4
OneWire oneWire(ONE_WIRE_BUS);
DallasTemperature sensors(&oneWire);
float Temp = 0;
#define dataPin 5;
dht DHT;
void setup() {
sensors.begin();
Serial.begin(9600);
myStepper.setSpeed(60);
Serial.begin(9600);
pinMode(3,OUTPUT);
pinMode(2,OUTPUT);
Serial.begin(9600);
}

void loop() {
int a=0;
```

```
sensors.requestTemperatures();
Temp = sensors.getTempCByIndex(0);
int readData = DHT.read11(dataPin);
fload t = DHT.temperature;
fload h = DHT.humidity;
if( Temp < 28 && t>18,h>40  )
{
digitalWrite(3,HIGH && 2,HIGH);
if( a == 0)
{
a=1;
myStepper.step(200);
}
}

 else {
  digitalWrite(2,LOW && 2,LOW):
  myStepper.step(-200);
  delay(2000);
 }
 delay(1000);

}
```

CHAPTER 7

RESULT AND CONCLUSION

7.1. RESULT

As give 5V or 12V power to Arduino and Stepper motor and then stepper belt and key is connected to stepper motor in upper side of greenhouse. The polyethene film roof is connected to stepper belt for moment and then ventilation fan and submerged pump with pipe line, water sprayer is connected to lower side of greenhouse roof. When 5V power to give ventilation fan and Submersible pump constantly. So when a temperature range to reach more than 28°C to automatically close the roof for reducing heat effect on plants then decreasing temperature range is less than 28°C to open the roof. At the same time to measure humidity range in inside the greenhouse and increasing air temperature range is automatically run ventilation fan and sprayed water for reducing effect of heat. It is a process are continuously work with help of power source.

Fig.4.11 Sensors output

7.2. CONCLUSION

This project developed the Automatic roof and environmental condition control system with help of electronic components. This projects are mainly used to reducing impact of high sunshine, temperature, heat etc and to protecting plants from the diseases, hot air and some times it is structure are used to against of pest and insects attack. This prototype is working of automatically, so any human not interface to control or maintained the environments inside the greenhouse. This project obtain two types of cultivation system such as first is open cultivation system another one is protected cultivation system. This methods is used to increasing crop growth rate and agriculture productivity. It is not create any pollution, low power consumption, low economical and eco-friendly. This method is mainly suitable to horticulture and floor gardening system.

SEPTEMBER 2020

ABSTRACT

Aeroponics growing of plants is becoming a household name for growing plants for their daily food at their kitchen table in metropolitan regions. When the prices of vegetables are growing high and the quality is not fresh farm, above all they all are not chemical free. Because this is a soil-less technique of growing plants, the manual work is cut down considerably while leaving no traces of soil stains. Once it is designed and placed, it begins to operate mechanically with minimum garden work is done to be taken care of. Aeroponics farming can be done to develop few plants to a high number of crops and types growing together by utilizing the maximum distance of a given unused spacing in the home.

CHAPTER 1
INTRODUCTION

1.1.GENERAL

Recently, the application of Vertical Farming into cities has increased. Vertical farming is a cultivating vegetable vertically by new agricultural methods, which combines the design of building and farms all together in a high-rise building inside the cities. This technology needs to be manifest both in the agricultural technique and architectural technology together. However, little has been published on the technology of Vertical Farming."We live vertically, so why can't we farm vertically?" Due to the limited access to land for farming, there is a need for sustaining farming tasks so as to pave the way for adding to food needs. Many aspects press on food industry and processing such as growth of population and its growing needs accordingly, reduction of natural sources due to growing cities, earth erosion, different forms of contamination, advent of biofuels, restrictions imposed on food production techniques affected by customers and rule providers which requires better quality, less use of chemicals and many useful environmental attempts 'from farm to fork'. Recently, environmental obsessions have been mixed with rising obsession with health as architecture design is concerned. Therefore, it has led to more interest in providing healthy food and incorporating it in the sustainable development project . The answer to these issues is Vertical Farming (VF). VF has grown as a project which combines the design of building and farms all together in a high-rise building. VF is a system of growing crops in skyscrapers, to maximize the use of land by having a vertical design whereby plants, animals, fungi and other life forms are cultivated for food, fuel, fiber… by artificially stacking them vertically above each other .Vertical farms are now used in a lot of countries. At present, these farms are largely grown and produce different types of crops inside cities.

Aeroponics growing of plants is becoming a household name for growing plants for their daily food at their kitchen table in metropolitan regions. When the prices of vegetables are growing high and the quality is not fresh farm, above all they all are not chemical free. Because this is a soil-less technique of growing plants, the manual work is cut down considerably while leaving no traces of soil stains. Once it is designed and placed, it begins to operate mechanically with minimum garden work is done to be taken care of. Aeroponics

farming can be done to develop few plants to a high number of crops and types growing together by utilizing the maximum distance of a given unused space in home.

OBJECTIVES:

- To make farming easier to manage.
- To increase plant growth rate and yield.
- To produce disease free crops.
- To minimize the use of water.

CHAPTER 2

LITERATURE REVIEW

MODERN PLANT CULTIVATION TECHNOLOGIES IN AGRICULTURE UNDER CONTROLLED ENVIRONMENT

***Imran Ali Lakhiar,Jianmin gao,Tabinda Naz Syed*30 may 2018**

This review paper describes a novel approach to plant cultivation under soil-less culture. At present, global climate change is expected to raise the risk of frequent drought. Agriculture is in a phase of major change around the world and dealing with serious problems. In future, it would be difficult task to provide a fresh and clean food supply for the fast-growing population using traditional agriculture. Under such circumstances, the soil-less cultivation is the alternative technology to adapt effectively. The soil-less system associated with the Hydroponic and Aeroponics system. In the aeroponics system, plant roots are hanging in the artificially provided plastic holder and foam material replacement of the soil under controlled conditions. The roots are allowed to dangle freely and openly in the air. However, the nutrient rich-water deliver with atomization nozzles. The nozzles create a fine spray mist of different droplet size at intermittently or continuously. This review concludes that aeroponics system is considered the best plant growing method for food security and sustainable development. The system has shown some promising returns in various countries and recommended as the most efficient, useful, significant, economical and convenient plant growing system then soil and other soil-less methods.

POTENTIAL OF AEROPONICS SYSTEM IN THE PRODUCTION OF QUALITY POTATO

***M Chiipanthenga,M Maliro,P Demo,J Njoloma*13 feb 2014**

The production of potato seed under conventional system has not been effective in avoiding or reducing the build up of pathogens and has consequently led to reduced quality potato seed and low crop yields. Plants once cleaned through meristem culture and induction of tuberization under aeroponics system, produce high quality potato seed tubers rapidly that are free from contamination of pathogens. Further multiplication of potato seed tubers under aeroponics also compliments tissue culture (micropropagation), as it clones minitubers in a short time and reduces numerous labour steps associated with direct use of plantlets from tissue culture into the field in the post flask stage. Minitubers from air-rooted plants are planted directly in the field without a need for acclimatization to such environments. This system, as is the case with micropropagation, has potential to increase income and reduce cost

of production of quality seed, thereby, making it more accessible to growers in developing countries where potato production is heavily constrained by the use of poor quality seed tubers. This review gives an insight on the potential of aeroponics in compliment to plant tissue culture in revolutionalizing the potato seed production in the agricultural systems of developing countries.

AEROPONICS FOR THE CULTURE OF ORGAISMS, TISSUES AND CELL

P.J.Weathers*

Characteristics of aeroponics are discussed. Contrast is made, where appropriate, with hydroponics and aero-hydroponics as applies to research and commercial applications of nutrient mist technology. Topics include whole plants, plant tissue cultures, cell and microbial cultures, and animal tissue cultures with regard to operational considerations (moisture, temperature, minerals, gaseous atmosphere) and design of apparati.

AUTOMATIC AEROPONIC IRRIGATION SYSTEM BASED ON ARDUINO'S PLATFORM

A P Montoya[1], F A Obando[1], J G Morales and G Vargas **, 1 June 2017**

The recirculating hydroponic culture techniques, as aeroponics, has several advantages over traditional agriculture, aimed to improve the efficiently and environmental impact of agriculture. These techniques require continuous monitoring and automation for proper operation. In this work was developed an automatic monitored aeroponic-irrigation system based on the Arduino's free software platform. Analog and digital sensors for measuring the temperature, flow and level of a nutrient solution in a real greenhouse were implemented. In addition, the pH and electric conductivity of nutritive solutions are monitored using the Arduino's differential configuration. The sensor network, the acquisition and automation system are managed by two Arduinos modules in master-slave configuration, which communicate one each other wireless by Wi-Fi. Further, data are stored in micro SD memories and the information is loaded on a web page in real time. The developed device brings important agronomic information when is tested with an arugula culture (*Eruca sativa* Mill). The system also could be employ as an early warning system to prevent irrigation malfunctions.

SPORE DEVELOPMENT OF *Entrophospora kentinensis* IN AN AEROPONIC SYSTEM

Chi-Guang Wu ,Yen-Sher Liu &Ling

29 Aug 2018

Entrophospora kentinensis was propagated with bahia grass and sweet potato in an aeroponic system. Spores were produced 6 weeks later after host plants were transferred to an aeroponic chamber. Sporiferous saccules were formed either by external mycelium or within roots. Sporogenesis started inside the stalk of a sporiferous saccule by the formation of a septum in the lower channel of the stalk. The cytoplasm within the saccule seemed the major source for the spore formation. When the cytoplasm flowed downward, the central part of the stalk swelled and tiny vacuoles were formed at the periphery of the saccule. As the primordial spore was differentiated inside the stalk, another septum was formed right below the saccule. After spores mature, the terminal vesicles of saccules and the lower hyphal stalks degenerate and leave Differences in spore between *Acaulospora* and *Entrophospora* are discussed.

OVERVIEW OF THE AEROPONIC AGRICULTURE –AN EMERGING TECHNOLOGY FOR GLOBAL FOOD SECURITY

Imran Ali Lakhiar, Jianmin Gao, Tabinda Naz Syed, Farman Ali Chandio, Mazhar Hussain Tunio, Fiaz Ahmad, Kashif Ali Solangi

Jan 13 2020.

Traditionally, crops are cultivated in soil-based open field systems. Seasonality, environmental degradation, urbanization, and food security issues have replaced open-field systems with modern plant production systems. Soilless culture is one of the modern plant production systems, which involves much higher use of available resources. The presented study provides information about currently accessible soilless systems and discussed the aeroponic system. Compared to other soilless systems, aeroponic reduce water usage through continuous water circulation. However, the aeroponic is not entirely implemented among local farmers, and very few farmers have adopted the system due to the lack of research and technical information available in the literature. Therefore, this study was planned to provide information about the development and maintenance tasks required for practicing the aeroponic system. This study could provide knowledge to the researchers, farmers, and those people interested in practicing the aeroponic system.

FUTURE FOOD PRODUCTION SYSTEMS :VERTICAL FARMING AND CONTROLLED ENVIRONMENT AGRICULTURE

Kurt Benke &Bruce Tomkins

20 Nov 2017

The unremitting trends of increasing population, urbanization, diminishing water supply, and continuing climate change have contributed to declining stocks of arable land per person. As land resources for agriculture decrease, policy makers are faced with the challenge of sustainability and feeding the rapidly growing world population which is projected to reach approximately 9.7 billion in 2050. Solutions for improving future food production are exemplified by urban vertical farming which involves much greater use of technology and automation for land-use optimization. The vertical farm strategy aims to significantly increase productivity and reduce the environmental footprint within a framework of urban, indoor, climate-controlled high-rise buildings. It is claimed that such facilities offer many potential advantages as a clean and green source of food, along with biosecurity, freedom from pests, droughts, and reduced use of transportation and fossil fuels. In this article, the issues involved are evaluated together with potential advantages and disadvantages. Possible implications are identified for consideration by policy makers and to facilitate further economic analysis.

CONCEPT OF EXPERIMENTAL PLATFORM TO INVESTIGATE AEROPONIC SYSTEMS IN MICROGRAVITY CONDITIONS

AnnaJurga, JoannaKuźma, PawełPłuszka, PiotrChmielewsk[2], Edyta Bobrowska and Maciej Dragula

13 JULY 2018

The article presents the concept of experimental research system to investigate aeroponic cultivation in microgravity condition. The main scientific objective is to define the forces acting in droplet-root system exposed to microgravity conditions especially the adhesion and cohesion phenomena. The concept of a research platform is presented in this paper and includes electrical, hydraulic and optical system.

LOW EFFORT MANAGEMENT OF BASIL (OCIMUM BASILICUM) GROWTH IN AN AEROPONIC SYSTEM

Adam S. Vassallo

APRIL 2018.

Empowering individuals in high-density urban environments with the tools to affordably grow their own food with minimal effort could be a solution to sustainably

increase global food security. Aeroponic farming could potentially be used to achieve this goal. This study investigates the low effort maintenance of basil (Ocimum basilicum) growth in an aeroponic system. Aeroponic units that were supplied with nutrients and water at the start of a twentyeight-day experiment (experimental treatment) were compared with units where the nutrients and water were replaced on a weekly basis (reference treatment). This experiment was run twice, the first trial under solar light, and the second trial under T5 fluorescent light. The differences in biomass yields between trials was visibly noticeable, however not statistical significantly different. The biomass yield between treatments was not statistically significantly different. At the end of the first trial (solar light), the experimental treatment and reference treatment had mean total wet weights of 0.0182 g and 0.0151 g respectively. At the end of the second trial (T5 fluorescent light), the experimental treatment and reference treatment had mean total wet weights of 1.6564 g and 1.6484 g respectively. Further research using a longer experimental trial with more samples should be conducted to test for statistical biomass variance between treatment groups and between trials.

RE EXAMINING AEROPONICS FOR SPACEFLIGHT PLANT GROWTH

JM Clawson, A Hoehn, LS Stodieck, P Todd, RJ Stoner **2000**

Aeroponics is the process of growing plants in an air/mist environment without the use of soil or an aggregate media. Aeroponics has contributed to advances in several areas of study including root morphology, nutrient uptake, drought and flood stress, and responses to variations in oxygen and / or carbon dioxide root zone concentrations. The adaptability of the aeroponic process that has benefited researchers makes its application to spaceflight plant growth systems appealing. Greater control of growth parameters permits a greater range of crop performance throttling and the elimination of aggregates or common growth substrates lower system mass, lessens disease propagation between plants, and can decrease the required crew time for both planting and harvesting. However, because of the use of less reliable types of aeroponic techniques and concerns with open two phase fluids within the root zone in microgravity, many advanced life support technology researchers opted for nutirient delivery concepts that offered more fluid control, containment and simpler subsystem designs. The resulting systems have been successful for on-orbit plant growth, but have yet to achieve high performance crop production equal to terrestrial standards. Re-examining historical concerns, along with an overview of recent work demonstrating hypogravity aeroponics, shows the promise that aeroponics still holds for spaceflight crop production.

VERTICAL FARMING SUSTAINABILITY AND URBAN IMPLICATIONS

***DANIELA GARCIA-CARO BRICEÑO* ,2018**

Vertical Farming Sustainability and Urban Implications. Masterthesis in Sustainable Development at Uppsala University, No.2018/32,80 pp, 30 ECTS/hp Abstract: Meeting current and future demands for food is one of the biggest problems facing the world today. Despite the positive correlation that exists between food production and urban food demand, food systems remain separate and excluded from cities. Vertical farming has been proposed as a solution projected to address these issues in a sustainable way. This study aims to determine the sustainability of a vertical farm operation and its perceived value to food security and urban systems. This study implements a qualitative approach and case study research design useful for small, applied research studies, where data is collected via a literature review, emails, and semistructured interviews. Systems theory is used to frame the phenomena at hand since it allows for a holistic systems view, and the study's results are analyzed using emergy theory and a conceptual framework based on urban political agroecology. A vertical farm was selected as the focus of the case study, with the vertical farm sustainability serving as this study's unit of analysis. Contrary to existing information, the results indicate that the vertical farm studied is unsustainable due to its dependence on imported resources. Additionally, an assessment of vertical farm impacts through a conceptual framework on urban political agroecology determined that vertical farming is incompatible with agroecological principle, provides few positive impacts to urban systems, and makes most of its contributions to urban food security rather than food sovereignty. For the sustainable development of vertical farms and urban systems, emergy theory stresses that inputs into the system must be local renewable inputs (i.e. natural inputs located within the system boundaries), and that successful systems should create and implement reinforcing feedbacks. Nonetheless, vertical farming systems are quite immature and carry great potential for change; this study presents recommendations for vertical farming systems reorganizing more sustainably.

THE EFFECT OF NUTRIENT SOLUTIONS ON YIELD AND MACRONUTRIENT STATUS OF GREENHOUSE TOMATO GROWN IN AEROPONIC AND ROCKWOOL CULTURE WITH OR WITHOUT RECIRCULATION OF NUTRIENT SOLUTION

Komosa, A. ; Kleiber, T. ; Markiewicz, B. ,2014

Aeroponics creates possibilities to cultivate plants without soil or substrate, obtaining the optimal yield, saving water and nutrient solutions and do not contaminate the environment. In a three year experiment was shown that the higher total and marketable yields tomato cv. of 'AlboneyF_1' were in cultivation in rock wool with re circulating nutrient solution. Lower yields, however being in the same significance range, were in rock wool without recirculation of nutrient solution and aeroponic culture with A-1 and A-2 nutrient solutions, but the lowest in aeroponics with A-3 nutrient solution. The saving of nutrient solution in aeroponic culture, in relation to the cultivation in rock wool with non-re circulating system, was 58.1%, but comparing with re circulating system 18.8%. Plants grown in aeroponic culture with application of A-2 and A-3 nutrient solutions had higher contents of N, P and K in leaves than cultivated in rock wool with or no recirculation and in aeroponic with A-1 nutrient solution. All tested nutrient solutions (A-1, A-2 and A-3) in aeroponic culture caused the higher contents of Mg in leaves than in rock wool cultivation. The highest Ca leaves contents were in plants grown in rock wool with re circulating nutrient solution and aeroponic culture with A-2 and A-3 nutrient solutions. Plants grown in rock wool without recirculation of nutrient solution shown the lowest Ca contents, however there was no symptoms of blossom end rot (BER) on fruits. The yield and macronutrient status of tomato in aeroponic culture with application of A-1 nutrient solution were similar to the plants grown in rock wool with non-re circulating standard nutrient solution A-2.

CHEMICAL CHARACTERISTICS OF SOIL LESS MEDIA

***Avner Silber* ,2019**

Typical soilless media are commonly defined by root constraint and limited volume of substrate and accordingly, low buffer capacity for solution composition and limited supply of nutrients. Therefore optimal plant production necessitates specific and different attention to the chemical characteristics of the substrates. The surface charge properties and the dissolution characteristics of the substrate solids are important since they affect the ionic composition of nutrient solutions. Throughout the growth period organic compounds excreted from the plant roots or resulting from decomposition processes accumulate in the substrate.

Consequently the surfaces of the newly formed solids become heterogeneous and the chemical properties of the mixture may be significantly different from those of the single, well-defined component that was characterized before use. The general objective of this chapter is to define the chemical characteristics of soilless media. The specific objectives are: (1) to describe the charge characteristics of typical substrate used in the horticultural industry and to assess the interactions between pH, solution concentration of cations\anions, and substrate solids, especially adsorption and precipitation reactions. Special attention was dedicated to describe the solubility and possible interactions of nutritional elements with the substrate and to discuss the expected horticultural implications and (2) to illustrate the effects of plant-induced changes in the rhizosphere and to evaluate its effects on plant nutrition.

A MIST CHAMBER FOR THE CULTURE OF PLANTS

C.A.BEASLEY AND W.P.FOX

1970

Versatile mist chambers, framed with aluminum and glass and having access from top and sides, permit culture of an extensive number of, and different types of, vegetative plant organs as well as seeds and plant pathogens. Pneumatic atomizing nozzles are staggered to permit division of the chamber, and the spray emitted can be regulated from each nozzle. The amount of water vapor emitted is regulated by changing the air pressure or siphon height. Gauge-monitored pressure regulators and solenoid valves control the air and spray system. Timing devices can be used to inject water vapor at desired intervals. Air passing through a condensation tube is recycled past cone heaters, providing temperature from ambient to 90 F, and a duct and baffle system provides uniformity of temperature throughout. A combination recorder and controller maintains the desired temperature.

AN ASEPTIC MIST CHAMBER SYSTEM :A METHOD FOR MEASURING ROOT PROCESS OF PEAS

***J. M. Smucker ,A. E. Erickson*, 21 March 1907**

Although plants have been grown with their roots in mist chambers and sterile nutrient solutions, these methods have not been combined to provide a system which permits rapid changes in the gaseous composition of an aseptic rhizosphere. The objectives of this study were to design a mist chamber system which would withstand heat sterilization, maintain an aseptic rhizosphere, permit rapid gaseous exchange without altering rootwater relationships, and permit the measurement of morphological and physiological root responses

without disrupting the system.A pyrex glass mist chamber system is described which permitted a complete exchange of the root atmosphere in 5 min. Pea (*Pisum sativum* L.) seedlings were treated from 6 to 17 days in the aseptic mist chamber. Root respiration, root exudation, and rhizosphere volatiles were monitored. Detection limits were 1.0 ppm of ethanol, 1.0 and 0.25 μ g for the TMSi amino acids and sugars.This system provides for concise control of the rhizosphere and precise measurements of root responses to environmental stresses.

ROCKWOOL IN HORTICULTURE, AND ITS IMPORTANCE AND SUSTAINABLE USE

***W.T.BUSSEL* ,March 2004**

A brief history of the beginnings of the use of rockwool in horticulture in overseas countries, an outline of uses overseas of the current forms of water absorbent and water repellent horticultural rockwool, a summary of manufacturers of the product, a consideration of some of its advantages and disadvantages, and a listing of the crops grown in horticultural rockwool are given in this paper. An outline of the overseas experiences in both the disposal of and the sustainable reuse of horticultural rockwool is also given. A history of use in New Zealand of horticultural rockwool and the crops grown on the product are outlined. Options, which are both within and outside horticulture, for the sustainable reuse of the relatively small volume (c. 300 m/year) which becomes available for reuse in New Zealand at present are described and discussed. Many of these options may be applicable in other countries .

POTENTIAL REPLACEMENTS FOR ROCKWOOL AS GROWING SUBSTRATE FOR GREENHOUSE TOMATO

Suzanne E. Allaire1, Jean Caron1, Claudine Ménard2, and Martine Dorais2
OCT 2004

The greenhouse industry needs renewable, cheap, and available substitutes for rockwool. The physical properties and performance of rockwool substitutes such as low grade peat, composted bark white spruce and fir, shavings, sawdust, and peat-bark mixtures were compared during two greenhouse experiments with tomato grown in plastic bags. Air and water filled porosities greatly differed between substrates, particularly for sawdust and shavings. Relative gas diffusivity (Ds /Do) and the hydraulic conductivity were less different between substrates. The physical properties of the substrates changed over a production cycle

but the changes were small compared to treatment differences. Yields in peat-bark substrates were similar to rockwool substrates during both the short and long experiments but were lower in sawdust and shavings during the long experiment. The yield differences expected between media were less than the differences between some substrate physical properties of the various media. Yields were positively related to easily available water (EAW) and negatively related to Ds /Do and airfilled porosity (AFP). This indicated excessive drainage for the low-yielding substrates. In plastic bags, media properties related to aeration were not good indicators of production because the plants adapted to the lack of aeration by modifying their root distribution. White spruce and fir bark alone or mixed with low-grade peat showed high potential for greenhouse tomato production and represent an environmental sound alternative to rockwool.

PRELIMINARY STUDIES ON THE USE OF AEROPONICS FOR VEGETABLES CROPS UNDER LOCAL CONDITIONS

***A.F. Abou-Hadid, M.Z. El-Shinawy, M.A. Medany,* 1994**

The need for aeroponics was increased after facing the problems of soil-born diseases, the low plant density in hydroponics, and the relatively high water consumption in both soil and hydroponic cultures. The aeroponic system was found to be an efficient way for maximizing plant density per square meter. In addition, water consumptive use was as efficient as that of the hydroponics. A simple construction for the use of "A, Shape" aeroponic in vegetable production is discussed. Some problems occurred and suggestion for overcoming them were discussed. Nutrient analysis showed a significant increase in K, Cu and Mn in the sun side compared to the shade, while the contrary occurred for N and Zn.

GROWTH RESPONSE AND ROOT CHARACTERISTICS OF LETTUCE GROWN IN AEROPONICS ,HYDROPONICS AND SUBSTRATE CULTURE

***QianshengLi1,XiaoqiangLi2,BinTang3,MengmengGu1,*2014**

Aeroponics is a relatively new soilless culture technology, which may produce food in space limited cities or non-arable land with high water use efficiency. The shoot and root growth, root characteristics, mineral contents of two lettuce cultivars were measured in aeroponics, as compared with hydroponics and substrate culture. The results showed that aeroponics remarkably improved the root growth with a significant greater root biomass,

root/shoot ratio, and several times higher total root length, root area and root volume. However, the greater root growth did not lead to a better shoot growth compared with hydroponics, due to the limited availability of nutrients and water. It can be concluded that aeroponics systems may be better for high value true root crops production. Further research is necessary to figure out the suitable pressure, droplet size, and misting interval in order to improve the continuously availability of nutrients and water in aeroponics, if it is used to grow crops like lettuce.

CRUSHED ROCKWOOL AS A COMPONENT OF GROWING SUBSTRATES

MARTIN DUBSKY , January 2008

The possibility of peat replacement by crushed water absorbent rockwool in amount of 25 and 35% vol. in four types of substrates (peat one, 3 mixtures with alternative components -green waste compost and composted spruce bark) was verified in the experiments with ornamental shrubs and perennials in containers and with pot plants. Chemical (content of available nutrients and potential for nitrogen fixation) and physical (water capacity) properties of the components and substrates were determined. In the peat substrate, the addition of rockwool affected positively the plant growth. It increased water capacity and improved wettability of the peat substrate after irrigation. Plants grown in mixtures with lower content (to 40% vol.) of alternative components also had good market value. In mixtures with higher content of alternative components (65% vol.) lower water capacity and high potential for nitrogen fixation showed negatively. The addition of rockwool to substrates with alternative components had no significant effect. The addition of 25 or 35% vol. crushed rockwool can replace.

SURVEY PAPER ON AEROPONICS

Ajay kumar D , Namratha S, **2018**

Almost all plants need soil for their growth. Nutrients present in soil help in the development of plants. Aeroponics is the method of growing plants in a medium without the use of soil. Here the plants are provided with a nutrient solution which circulates in the medium that holds the plant. The nutrient solution contains macronutrients and micronutrients which contribute to the healthy growth of plant. The Aeroponics is based on the opportunity of cultivating fruits & vegetables whose roots are not implanted in a bedrock (the case with hydroponics) or soil, but in ampules in which practices for spraying plant nutrition is

CHAPTER 3

MATERIALS AND METHODS

3.1MATERIALS USED:

- PVC Pipe
- Fish Amino Acid
- Mesh Bucket
- Rockwool
- Motor
- Seed Tray
- Lettuce and Cucumber Seeds
- Mist Chamber

FIGURE 3.1: SEED TRAY

PROPERTIES OF SEED TRAY:

- ❖ Non toxic
- ❖ Light weight
- ❖ Do not damage roots
- ❖ Save seeds

FIGURE.3.2.MESH BUCKETS

PROPERTIES OF MESH BUCKETS:

- Plant holder
- Promote healthy roots
- Even drainage
- Proper aeration

FIGURE.3.3 ROCK WOOL

PROPERTIES OF ROCKWOOL:

- It has better water holding capacity.
- It helps in increasing root zone activity
- It is light weight
- Soilless germinating medium.

PROPERTIES OF MISTCHAMBER:

- It maintains ambient humidity and temperature
- It induces rooting and acclimatization
- It gives cooling effect and prevent drying
- It helps to spray water and nutrients to the plant roots

FIGURE.3.4 PVC PIPES.

PROPERTIES OF PVCPIPE:

- Tensile strength
- It helps to hold mesh buckets with plants
- Useful for vertical farming

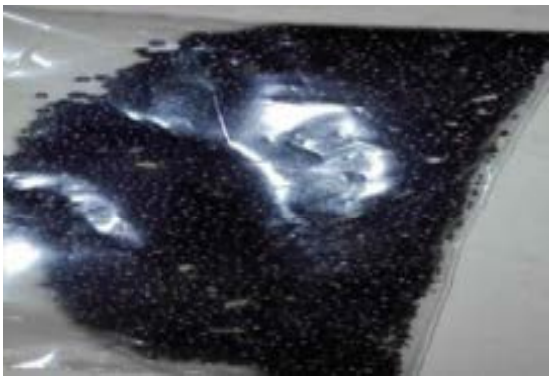

FIGURE:3.5 LETTUSE SEEDS.

Kingdom: Plant

Order: Asterales

Family: Asteraceae

PROPERTIES OF LETTUSE SEEDS:

Lettuce is an annual plant of the daisy family, Asteraceae. It is most often grown as a leaf vegetable, but sometimes for its stem and seeds. Lettuce is most often used for salads, although it is also seen in other kinds of food, such as soups, sandwiches and wraps; it can also be grilled. One variety, the woju, or asparagus lettuce, is grown for its stems, which ar`e eaten either raw or cooked. In addition to its main use as a leafy green, it has also gathered religious and medicinal significance over centuries of human consumption. Europe and North America originally dominated the market for lettuce, but by the late Light – either direct sunlight for an outdoor vertical garden or artificial grow lights for an indoor one.

1. Air circulation – which can help cool down lettuce in outdoor vertical gardens.
2. Cool temperatures – ideally between 65 and 70F.
3. Fluffy well-aired soil.
4. High nitrogen fertilizer.
5. A watering system.

A "grow light" is simply an artificial form of sunlight. Plug them in, arrange to direct them onto the plants and watch them grow. There are increasingly abundant choices in styles and strength, but what is more important is in how possible this is. Nor do they need to cost an arm and a leg and nor do they have to eat up electricity like a hog. LED lights run on less than 18% of wattage used by standard house lamps and are every bit as effective and adjustable.

3.2 Use vertical air circulation to cool off your lettuce plants:

Vertical gardens can offer a unique level of air circulation. For one thing, they offer an unimpeded air circulation owing to the lack of competition that they would have in the ground. You see, when you plant lettuce in the ground, it's likely to get in contact with rivaling plants underground. Raised above ground level, it's much harder for other plants to get in the way.Air circulation also helps with lowering temperature. Because they are a plant which thrives in cooler weather, the obvious effect of sunshine building heat on the ground would make lettuce less harvestable in warmer months, and earlier so than when raised. That's where growing lettuce vertically can come in handy.

3.3 Assess the temperature for optimal growing conditions:

In as much as lettuce is typically referred to as a "cool weather plant", the term is somewhat relative. Factors such as shade and the possibility of growing indoors are obvious outliers. Nevertheless, lettuce grows best with temperatures between 60 and 65 degrees. At 70-80 degrees the lettuce plants tend to grow flowers and produce seeds.These plants can tolerate temperatures from 80-85 degrees, but only temporarily for optimal growing conditions. If you're growing lettuce in an indoor vertical garden, consider leaving the a/c during heat waves.

Throw in some fertilizer Help your lettuce grow faster and better by adding some high-nitrogen fertilizer into the planting medium during seeding. This will get the plants off to a more rapid start once they can tap in through their roots. Lettuce, in this sense, is easier to fertilize than plants which require stem or foliage growth. High nitrogen organic sources include fishmeal, blood meal, and cottonseed meal. Premixed chemical or natural fertilizers high in nitrogen include

mixes. The first number refers to the proportion of nitrogen to the other two major elements: phosphorus and potassium. Vertical gardens offer a far easier methodology for fertilizing in that many of the plants could be far above the ground to get closer to and tend without spillage or mess.

3.4 Finally put a good watering system in place:

Whether indoors or outside, you'll need a watering system for your vertically-growing lettuce. For those who can afford to spend a little, drip systems offer an amazing freedom in that they run a preset amount of water at preset intervals and times of day. It takes a bit of tweaking to find out the ideal water amount and when to apply it, but once you hit that sweet spot, an automatic drip system will allow you to travel without worrying about your developing lettuce. Can't afford an automated watering system, That's ok. You can still grow lettuce vertically with manual watering. Apply water using a squeezable watering container with the long tube formed to bend over the edges of the plant container. These terrific inventions can allow you to apply exact amounts of watering without making a mess.

AEROPONICS:

Aeroponics is the process of growing plants in an air or mist environment without the use of soil or an aggregate medium. The word "aeroponic" is derived from the Greek meanings of air and ponos. Aeroponic culture differs from both conventional hydroponics, aquaponics, and in-vitro (plant tissue culture) growing. Unlike hydroponics, which uses a liquid nutrient solution as a growing medium and essential minerals to sustain plant growth; or aquaponics which uses water and fish waste, aeroponics is conducted without a growing medium.It is sometimes considered a type of hydroponics, since water is used in aeroponics to transmit nutrients.

3.5 METHODS:

The basic principle of aeroponic growing is to grow plants suspended in a closed or semi-closed environment by spraying the plant's dangling roots and lower stem with an automized or sprayed, nutrient-rich water solution. The leaves and crown, often called the canopy, extend above. The roots of the plant are separated by the plant support structure. Often, closed-cell foam is compressed around the lower stem and inserted into an opening in the aeroponic chamber, which decreases labor and expense; for larger plants, trellising isused

to suspend the weight of vegetation and fruit.Ideally, the environment is kept free from pests and disease so that the plants may grow healthier and more quickly than plants grown in a medium. However, since most aeroponic environments are not perfectly closed off to the outside, pests and disease may still cause a threat. Controlled environments advance plant development, health, growth, flowering and fruiting for any given plant species and cultivars.Due to the sensitivity of root systems, aeroponics is often combined with conventional hydroponics, which is used as an emergency "crop saver" – backup nutrition and water supply – if the aeroponic apparatus fails.High-pressure aeroponics is defined as delivering nutrients to the roots via 20–50 micrometre mist heads using a high-pressure (80 pounds per square inch (550 kPa)) diaphragm pump.

3.6 BENEFITS OF OXYGEN IN ROOT ZONE:

Oxygen (O2) in the rhizosphere (root zone) is necessary for healthy plant growth. As aeroponics is conducted in air combined with micro-droplets of water, almost any plant can grow to maturity in air with a plentiful supply of oxygen, water and nutrients.

Some growers favor aeroponic systems over other methods of hydroponics because the increased aeration of nutrient solution delivers more oxygen to plant roots, stimulating growth and helping to prevent pathogen formation.

Clean air supplies oxygen which is an excellent purifier for plants and the aeroponic environment. For natural growth to occur, the plant must have unrestricted access to air. Plants must be allowed to grow in a natural manner for successful physiological development. The more confining the plant support becomes, the greater incidence of increasing disease pressure of the plant and the aeroponic system.Some researchers have used aeroponics to study the effects of root zone gas composition on plant performance. Soffer and Burger studied the effects of dissolved oxygen concentrations on the formation of adventitious roots in what they termed “aero-hydroponics.” They utilized a 3-tier hydro and aero system, in which three separate zones were formed within the root area. The ends of the roots were submerged in the nutrient reservoir, while the middle of the root section received nutrient mist and the upper portion was above the mist. Their results showed that dissolved O2 is essential to root formation, but went on to show that for the three O2 concentrations tested, the number of roots and root length were always greater in the central misted section than either the submersed section or the un-misted section. Even at the lowest concentration, the misted section rooted successfully.

3.7 DISEASE FREE CULTIVATION:

Aeroponics can limit disease transmission since plant-to-plant contact is reduced and each spray pulse can be sterile. In the case of soil, aggregate, or other media, disease can spread throughout the growth media, infecting many plants. In most greenhouses, these solid media require sterilization after each crop and, in many cases, they are simply discarded and replaced with fresh, sterile media.A distinct advantage of aeroponic technology is that if a particular plant does become diseased, it can be quickly removed from the plant support structure without disrupting or infecting the other plants.

Due to the disease-free environment that is unique to aeroponics, many plants can grow at higher density (plants per square meter) when compared to more traditional forms of cultivation (hydroponics, soil and Nutrient Film Technique [NFT]. Commercial aeroponic systems incorporate hardware features that accommodate the crop's expanding root system.

3.8 AEROPONICS FOR EARTH AND SPACE:

FIGURE.3.6.NASA AEROPONIC LETTUSE SEED GERMINATION:

In 1998, Stoner received NASA funding to develop a high performance aeroponic system for use on earth and in space. Stoner demonstrated significantly increased growth rates of dry biomass in lettuce plants grown in aeroponic systems compared to other cultivation techniques. NASA subsequently utilized numerous aeroponic advancements developed by Stoner.

Research was conducted to identify and develop technologies for rapid plant growth in a variety of gravitational environments. Low-gravity environments pose problems like effectively delivering water and nutrients to plants and recovering the effluents. Food production in space faces other challenges including water handling, minimization of water use, and minimization of the systems weight. Food production on planetary bodies like the Moon and Mars will also require dealing with reduced gravity environments. Because of the different fluid dynamics present at differing levels of gravity a major focus in developing plant growth systems has been optimizing nutrient delivery systems.

There are a number of nutrient delivery methods currently utilized (both on Earth and in low gravity). Substrate dependent methods include traditional soil cultivation, zeoponics, agar, and nutrient-loaded ion exchange resins. In addition to substrate dependent cultivation, many methods that don't use soil have been developed including the nutrient film technique, ebb and flow, aeroponics, and many others. Because of their high nutrient solution throughput hydroponic systems can produce rapid plant growth. This necessitates large water volumes and substantial recycling of the solution which makes controlling solutions more difficult in microgravity conditions.

To deliver nutrients aeroponic systems use hydro-atomized sprays that minimize water use, increase root oxygenation, and produce excellent plant growth. The nutrient solution throughput of aeroponic systems is higher than in other systems developed to operate in low gravity. Aeroponics' elimination of substrates and the need for large nutrient stockpiles reduce the amount of waste material that needs to be processed by other life support systems. The removal of the need for a substrate also simplifies planting and harvesting (making automation easier), decreases the weight and volume of expendable materials, and eliminates a potential pathogen transmission pathway. These advantages demonstrate the potential of aeroponic production in microgravity and the efficient production of food in outer space.

3.9 NASA INFLATABLE AEROPONICS:

In 1999, Stoner, funded by NASA, developed an inflatable low-mass aeroponic system (AIS) for space and earth for high performance food production.This advancements are very useful in space aeroponics.Aeroponics International's (AI's) innovation is a self-contained, self-supporting, inflatable aeroponic crop production unit with integral environmental systems for the control and delivery of a nutrient/mist to the roots.

This inflatable aeroponic system addresses the needs of subtopic 08.03 Spacecraft Life Support Infrastructure and, in particular, water and nutrient delivery systems technologies for food production. The inflatable nature of our innovation makes it lightweight, allowing it to be deflated so it takes up less volume during transportation and storage. It improves on AI's current aeroponic system design that uses rigid structures, which use more expensive materials, manufacture processes, and transportation. As a stationary aeroponic system, these existing high-mass units perform very well, but transporting and storing them can be problematic.

On Earth, these problems may hinder the economic feasibility of aeroponics for commercial growers. However, such problems become insurmountable obstacles for using these systems on long-duration space missions because of the high cost of payload volume and mass during launch and transit.The NASA efforts lead to developments of numerous advanced materials for aeroponics for earth and space.

BENEFITS OF AEROPONICS FOR EARTH AND SPACE:

NASA aeroponic lettuce seed germination- Day 3

Aeroponics possesses many characteristics that make it an effective and efficient means of growing plants.Plants grown using aeroponics spend 99.98% of their time in air and 0.02% in direct contact with hydro-atomized nutrient solution. The time spent without water allows the roots to capture oxygen more efficiently. Furthermore, the hydro-atomized mist also significantly contributes to the effective oxygenation of the roots. For example, NFT has a nutrient throughput of 1 liter per minute compared to aeroponics' throughput of 1.5 milliliters per minute.The reduced volume of nutrient throughput results in reduced amounts of nutrients required for plant development.

Another benefit of the reduced throughput, of major significance for space-based use, is the reduction in water volume used. This reduction in water volume throughput corresponds with a reduced buffer volume, both of which significantly lighten the weight needed to maintain plant growth. In addition, the volume of effluent from the plants is also reduced with aeroponics, reducing the amount of water that needs to be treated before reuse.The relatively low solution volumes used in aeroponics, coupled with the minimal amount of time that the roots are exposed to the hydro-atomized mist, minimizes root-to-root contact and spread of pathogens between plants.

GREAT CONTROL OF ENVIRONMENT:NASA aeroponic lettuce seed germination (close-up of root zone environment)- Day 19.Aeroponics allows more control of the environment around the root zone, as, unlike other plant growth systems, the plant roots are not constantly surrounded by some medium (as, for example, with hydroponics, where the roots are constantly immersed in water).

IMPROVED NUTRIENT FEEDING**:**

A variety of different nutrient solutions can be administered to the root zone using aeroponics without needing to flush out any solution or matrix in which the roots had previously been immersed. This elevated level of control would be useful when researching the effect of a varied regimen of nutrient application to the roots of a plant species of interest. In a similar manner, aeroponics allows a greater range of growth conditions than other nutrientdelivery systems. The interval and duration of the nutrient spray, for example, can be very finely attuned to the needs of a specific plant species. The aerial tissue can be subjected to a completely different environment from that of the roots.

MORE USER FRIENDLY:

The design of an aeroponic system allows ease of working with the plants. This results from the separation of the plants from each other, and the fact that the plants are suspended in air and the roots are not entrapped in any kind of matrix. Consequently, the harvesting of individual plants is quite simple and straightforward. Likewise, removal of any plant that may be infected with some type of pathogen is easily accomplished without risk of uprooting or contaminating nearby plants.

MORE COST EFFECTIVE:

Close-up of aeroponically grown corn and roots inside an aeroponic (air-culture) apparatus. Aeroponic systems are more cost effective than other systems. Because of the reduced volume of solution throughput (discussed above), less water and fewer nutrients are needed in the system at any given time compared to other nutrient delivery systems. The need for substrates is also eliminated, as is the need for many moving parts .

USE OF SEED STOCKS:

With aeroponics, the deleterious effects of seed stocks that are infected with pathogens can be minimized. As discussed above, this is due to the separation of the plants

and the lack of shared growth matrix. In addition, due to the enclosed, controlled environment, aeroponics can be an ideal growth system in which to grow seed stocks that are pathogen-free. The enclosing of the growth chamber, in addition to the isolation of the plants from each other discussed above, helps to both prevent initial contamination from pathogens introduced from the external environment and minimize the spread from one plant.

3.10 PS NUTRAC SERVICES:

Due to complexity of this new system our scientists are constantly doing research and experiments to expand the variety of plants this system works with.

The structure and system took years to assemble which makes it crucial for PSN to handle the setup and maintenance end to end as very little detail has been thoroughly researched and structured for reasons that the layman may not be aware of.

- Costruction/assemble of green or screen house
- Setup and construction of aeroponics structure
- Setup of system
- Providing,advising and planting of seeds or plants
- Full training with staff and supervisors on usage and harvest
- Maintanence of equipment and structure.

AEROPONICS KIT LAYOUT AND SETUP:

FIGURE.3.7.AEROPONICS KIT.

MAKING OF AEROPONICS KIT:

The PVC pipe of 3 feet is taken. To grow plants vertically in PVC pipe the holes are made into the side walls of the PVC pipe .The holes are made using a wooden rotary tool .The sizes of the holes is made based on the size of the mesh bucket as per to hold it. The mesh buckets are fixed into the holes of the PVC slantingly by using glue to hold the plants . The PVC pipe is placed in a water with a motor .The motor is connected to a pipe .The top end of the pipe contains a mist chamber from where water is sprayed to the plant

roots.Aeroponics is a method of farming that uses an automized. Nutrient mist as the growing substrate rather than soil or water. The technology has huge advantages in water consumption reduction and low space requirements, making it a great candidate for urban farming.The MIT Cityfarm team is researching the farming method by prototyping an aeroponics façade system in the Media Lab. While the team is concentrating on urban needs, aeroponics growing technologies could have just as huge an impact on food production in water-scarceregions, such as Israel, since aeroponics utilize 98% less water than conventional farming. By connecting Cityfarm and the Ecological Greenhouse of Kibbutz Ein Shemer in Israel for collaboration on improving the technology, teams from both sectors that can benefit from aeroponics can contribute to increasing the speed at which aeroponics advances and gains support. The Greenhouse functions based on a platform of combining social action, education, and research in marine agriculture, renewable energy, and agricultural technologies. At the Greenhouse, students from Jewish and Arab backgrounds learn about the agricultural sciences from educational staff, and they go on to contribute to projects either self-devised or initiated by the Greenhouse. With its knowledgeable staff and high traffic of students, the Greenhouse is an ideal incubator for experimenting with and improving aeroponics.A neglected corner of the Greenhouse was designated as aeroponics territory, and I got to work setting up, cleaning, and building with huge amounts of help and support from the Greenhouse staff. We had a first aeroponic system planted with lettuce and running by the second week. It was pretty soggy and very leaky, so we started working on the next versions with new designs and better materials, simultaneously working on a smaller-scale demonstration tank. We wanted to make aeroponics less of a mystery for students. Because so many tours and classes were visiting the aeroponics experiments, we set up a section purely for presentation. Instead of lifting the lids on the big aeroponic systems, we wanted students to be able to peer into a window and see the piping systems and suspended plant roots for themselves.

METHODOLOGY:

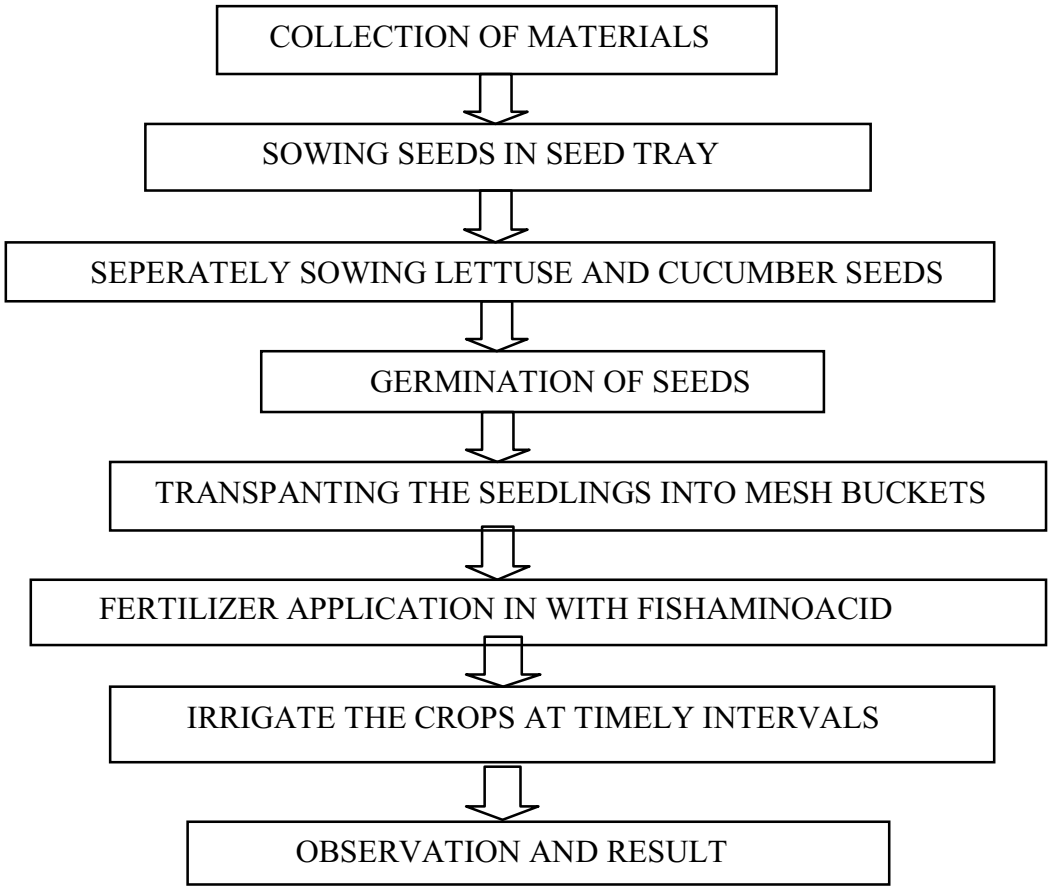

FIGURE 3.8: FLOW CHART OF THE PROJECT.

For evaluating the response of Green gram to seed inoculation with *Rhizobium* and use of Nitrogen fertilizer a pot culture experiment was conducted under natural conditions.The plants were sown by using four seeds per hole in a seed tray and sterlised soil was added in each polybag .Nitrogen fertilizer at 33.3g per polybag for Green gram were applied in the form of Diammonium phosphate (DAP). Fertiliser were applied at the time of transplanting of the untreated seedlings. For seed inoculation, seeds were coated with paste of rhizobium inoculum and left undisturbed for 30 minutes to get dry and sown in seedtrays. All agronomic practice were kept uniform and normal for all treatments. Three seed inoculated and three Nitrogen fertilizer added were used. Experiment was carried out for seven weeks. Data on seed germination, nodulation index, plant height at maturity,wet weight and dry weight was recorded. Five plants were randomly selected and uprooted from pot and washed in tap water. Then plants height and wet weight were recorded. Dry weights of these plants were recorded after keeping them in hot air oven at 60 0C for 8 hours.Nodules from seed inoculated plant were removed from root with the help of a sterlised blade and rhizobial cells were isolated by squash method.

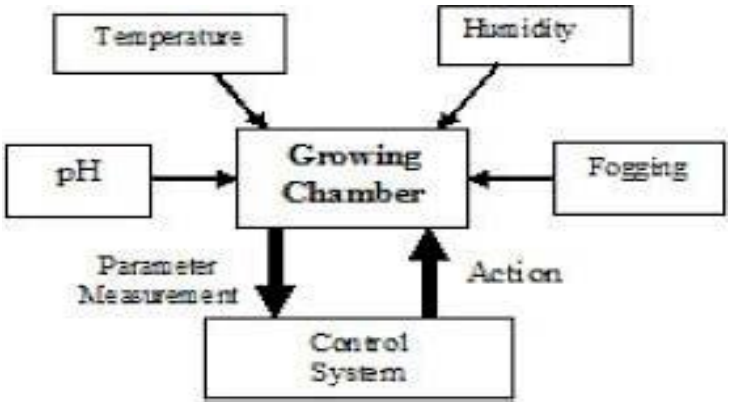

FIGURE.3.9: AEROPONIC GROWING SYSTEM

CHAPTER 4
RESULT AND DISCUSSION

Technical AnalysisInformants reported on the possibility of transferring andreplicating these technologies using local materials, equipment and personnel. None of the technologies have anypatents and all have been adapted locally. The difference related to the degree of or local adjustment. Theaeroponics and fiber-cement tiles technologies generallyneed a high degree of local adaptation, while the semi-hydroponics and conventional technologies require intermediate to modest levels of adaptation respectively. With regard to the aeroponics and fiber-cement tiles technologies,potential forreplicability in developing countries can berelatively low in light of requirements for equipment, external inputs and specialized personnel to ensure effectiveoperations. Semi-hydroponics is characterized by an intermediate degree of replicability because the use of solidsubstrates provides robustness. The conventional technology has a high degree of replicability.With regard to requirements for equipment, materials andinputs, the greatest need exists for aeroponics.

There is direct relationship between the degree of complexity and efficiency of the technologies evaluated.Technologies that were more complex and demanding inexpertise were also found to be more efficient in terms oftheir overall production output and economic performance.At the same time there is an inverse relationship between thedegree of complexity and the robustness of the differentmini-tuber production systems. The ability to withstandshocks, such as power or water cuts, is low for aeroponicsand the fiber-cement tiles technology. The conventionalsolid-substrate-based technology is the least complex andcertainly not as efficient as compared to the soilless system .However, it is the most robust technology among the different systems compared. In general, depending on a countryor region's context, different technologies that carefullybalance efficiency and robustness must be sought. Thus the yield and growth of the crops are observed and foud better with the comparitive cultivation with traditional cultivation and aeroponic system of cultivation.

CHAPTER 5

CONCLUSION

Aeroponics was a form of hydroponics technique where the plants are grown using mineral nutrient solutions instead of soil.Hydroponics and Aeroponics plays very important role for the commercial food production.Aeroponically grown plants will get perfectly balanced diet.In recent decades,NASA has done extensive project research for their Control Ecological Life Support System(CELSS). NASA sponsored Stoners research for natural liquid biocontrol,known then as ODC, that activates plants to grow without the need for pesticides as a means of control pathogens in closed loop culture system.Aeroponic bio-pharming is used to grow pharmaceutical medicine of plants.

Due to increase in world population and the need to face all their food customs this technically developed form of agriculture can be used which yield more then conventional agriculture and are cultivated as disease free crops and grown organically.

SEPTEMBER 2020

ABSTRACT

Our project focused on the design and fabrication of a groundnut pod stripper and Desheller machine on electrically powered by 1 hp motor. The machine has the capacity of stripping and shelling of 100 kg of groundnut per hour respectively. The machine was fabricated from locally soured materials of steel rod, bearing, shaft, ect.., which makes it cheap and easily affordable and also easy and cheaper to maintain. It is also of light weight and it consist hopper, Desheller, separator and blower unit.

KEYWORDS: Groundnut, farmer, time consumption, traditional method of pod separator and Desheller, Automatic pod separator and Desheller.

CHAPTER 1

INTRODUCTION

1.1 .GENERAL

Groundnut is the sixth most important oilseed crop in the world. It contains 46-50% oil and 25-28% protein, and is a rich source of dietary fiber, minerals and vitamins. It grows best on soils that are well drained, loosely textured and well supplied with calcium, potassium and phosphorous. Over 100 countries worldwide grow groundnut. The main purpose of this paper is to understand the knowledge of design and fabrication mechanism of portable groundnut Sheller machine. The design is very simple and eco-friendly which uses simple mechanism properties such as shelling system, automatic separating system and crushing chamber etc.

The study of manufacturing was very important for this project. In this project the process of designing the different parts of this shelling and separating machine considering all forces and ergonomic factor for people to use, This project is mainly about generating a new concept of groundnut shell (crush) that would make easier to transport anywhere and suitable to crush groundnut. After the design has completed, it was transformed to its real product where the design is used for guideline. A simple hand operated groundnut Sheller machine has a semi-cylindrical form closed on both sides. At one end shaft carrying a lever and which is fixed across the centre of the semi cylinder.

The major drawback of this machine is labour intensive and consumes lots of time. Output is about 20-30 kg/hour. But the particular design of this project reduces all the causes and improves the efficiency. It consists of the hopper, crushing chamber, separation chamber, blower unit and the frame for support. The crushing chamber and blower unit is powered by electrically which save the time. The machine is also light weight and easy to operate and maintain, the spare parts are also available locally. India is an agricultural based country. Since last 50 year's lot of changes has been occurred in agriculture sector. Many new agricultural based industries have been started new varieties

and species of plant have been discovered. In our country most of the people can be depend on the agriculture sector/field. The Groundnut is one of the products in the Marathwada-Nasik region. The product in the farm, in abundant quantity. There is lot of time waste in old method of groundnut pod separating. The time required for 1 Kg of groundnut pod separating from this groundnut is about 1 to 2 hours. so we have we have produces new machine for fast groundnut pod separating. In the Marathwada region people collect the groundnut from the groundnut plant directly for pod separating purpose.

The ground spreads on the ground and the pod of groundnut can be separated manually. Because of this method lot of time waste takes place as well as due to striking process some ground nut can be brakes of damage. But by using the groundnut pod separating machine we separate the pod from groundnut efficiently and large quantity in very less time. So we increase the work capacity and saving the time efficiently & effectively. So our machine in very useful to separating the pod from groundnut. Seed is the basic input in agriculture. However, for maximum gain in productivity the use of both improved varieties and improved integrated crop management practices are required. Not only do they contribute to increasing productivity individually, but they also act synergistically. In most of the conventional practices quality of groundnuts while plucking is harmed, so in order to avoid this groundnut plucking and sorting machine can efficiently pluck as well as sort groundnuts and hence better results can be obtained.

1.2. INITIAL CONCEPT

Introducing low cost automation was to overcome problems with the current manual traditional method. The concept of the work is,

- Observe the manual methods to identify the important process variables.
- Quantify the important method.
- Develop a prototype automation system which could control over all of the process.
- Investigate all areas of automated forming.

1.3. OBJECTIVES

- To minimize the time for separating the ground nut pod and desheller from plant body.
- To minimize man power.
- To simplify the process.
- To improve efficiency of operation of separation of groundnut pods from plant body.
- To develop a low cost machine this can be used by farmer
- It satisfies the need of village people to earn more money.
- The aim of project is to design & develop a low-cost groundnut pod separator which will help farmer to reduce time required to separate groundnuts.
- To reduce human efforts.
- To increase efficiency and get more profit.
- To reduce high requirement of labours.
- To modify the design of chaff cutting machine which can allow the farmer to not only cut the sugarcane in a form which can be utilized as a fodder for animal but can also grind various feeding materials such as dry corn straw, grass, soyabean, wheat stalk, with ease and thus reducing themanual work of farmer and increases the fodder production.

CHAPTER 2

REVIEW OF LITERATURE

ARBOGAST G. MBEIYERERWA (2016) reported that **SOCIO-ECONOMIC FACTORS LIMITING SMALLHOLDER GROUNDNUT PRODUCTION IN TABORA REGION**

"Groundnut is among the most important crops for smallholder farmers in Tanzania, providing both food and income for households. Groundnut is a nutritious source of fats, protein, carbohydrates, vitamins and minerals for human consumption and parts of the crop can be used for livestock feed. This study identified factors which contribute to the stagnation of groundnut production among smallholder producers in Rambo district of Tabora region in Tanzania. Quantitative data were collected using a survey questionnaire administered to 400 smallholder farmers. Multistage, simple random and purposive sampling were used to select participants. Qualitative data were also collected through focus group discussions, key informant interviews and personal observation. A multivariate regression technique was used to examine socio-economic factors influencing small-scale groundnut production in the district. In addition, the profitability of various crops produced in the study area was assessed using gross margin analysis. Results indicate that hours spent farming, cultivated land size, the price of groundnut from the previous season, cost of seeds and cost of pesticides significantly influence groundnut production in the area. Data further indicate that groundnut was the third most profitable crop in the area after beans and rice. The study also revealed gender disparity in land ownership. Few women owned land despite being major providers of labour. Based on the evidence, the study recommends that the government, among other policy responses, expand extension services to ensure that smallholder groundnut farmers have access to high-yielding groundnut seed varieties, agro-chemicals, improved farm inputs, storage and marketing facilities.

M.A. HAQUE (2016) reported that **PERFORMANCE EVALUATION OF A BAMBARA GROUND NUT SHELLER**

"The shelling of pod to obtain clean seed is one of the most tedious operations in Bambara groundnut processing. As a result, it has constituted a bottle- neck to the large scale production and processing of this important proteinous crop. To overcome the problem, some physical properties of bambara groundnut pod relevant in bulk handling andprocessing, were investigated and a sheller using roller mechanism was designed for the crop, constructed and tested.Measurements of the physical properties showed that at the moisture content of 5% (wb), the major, intermediate and minor diameters of Bambara groundnut pod averaged 1.89 cm, 1.57 cm and 1.44cm respectively. The true and bulk densities, porosity and one thousand-pod weight averaged 754.83 kg/m3 and 432 kg/m3, 42.77% and 1.24 kg, respectively and the angle of repose and static coefficient of friction of the pod on steel sheet averaged 30.4o and 0.56. Results of machine performance tests showed that the moisture content, material feed rate and the interaction between them had significant effect on the quantity of shelled, unshelled and partially shelled pods as well as that of damaged seeds and winnowed chaffs at 1% level of significance. Shelling and winnowing efficiencies decreased while percentage of partially shelled and unshelled pods increased with increase in moisture content and feed rate. The maximum shelling and winnowing efficiencies of 80% and 79.5% respectively, were obtained at the moisture content of 5% (wb) and feed rate of 93.6 kg/h. The percentage seed damage increased with increase in moisture content between 5 and 10% (wb) - to a maximum value of about 38%, and decreased with further increase in moisture content. At low moisture levels, it increased with increase in feed rate but at higher moisture levels, it decreased with increase in feed rate. Regression models that could be used to express the relationship existing between the sheller performance indices, pod moisture content and feed rate were established. Further work would be carried out to modify the sheller and optimize its performance.

A.N. GITAU, P.MBOYA, B.N.K.NJOROGE, M.MBURU (2015) reported that **PERFORMANCE OF A MANUALLY OPERATED GROUNDNUT DECORTICATOR**

"Shelling of groundnut pods using manual decorticators in Kenya is characterized by high kernel breakages and low shelling efficiencies. As a result, farmers get low income due to low cost of broken kernels and a lot of time is lost in the tedious shelling operation. To overcome this problem, pertinent parameters that influence shelling efficiency of manually operated groundnut decorticators were identified. Two manually operated decorticators were tested and modifications done on one of the decorticators to optimize its technical performance. Results of machine performance tests showed that for WBS (Wooden beater Sheller) at a feed rate of 30 kg/hr and 22.6 mm clearance, shelling efficiency in- creased with decrease in moisture content for all the groundnut varieties. The highest shelling efficiency was 55.3% for ICGV 99568, 39.2% for ICRISAT Groundnut Variety (ICGV) 90704 and 29% for ICGV 12991 at moisture content of 5.92% wb. For RBS (Rod Beater Sheller) at a feed rate of 30 kg/hr and 22.6 mm clearance, the highest shelling efficiency was 58.3% for ICGV 99568, 42.7% for ICGV 90704 and 35% for ICGV 12991 at moisture content of 7% wb. Identification of the pertinent parameters showed that pod moisture content, clearance and sieve size influence performance of manually operated groundnut. Theoretical predictive models developed were optimized which showed that a maximum shelling efficiency of 88.73% can be achieved with percent damage of 4% when the sieve size is 11 mm and clearance is 16 mm with a regression coefficient of over 85%. With the modifications done on the WBS decorticator, the highest shelling efficiency of 87% was obtained at a clearance of 10 mm for ICGV 99568 which is the largest in size from the three varieties. The shelling efficiency of the modified decorticator is far above those of the RBS and WBS because the sieve sizes and clearances of the later were not optimized. The results of the theoretical optimization of the manually operated groundnut decorticator implies that farmers who shell for seeds can now obtain more seeds shelled with low breakage and therefore will get more income.

SANTOSH MANGAVE AND BHAGYESH DESHMUKH ET AL (2015) reported that

DESIGNED THE PORTABLE GROUNDNUT SHELLER MACHINE.

"The fabricated machine is manually operated. Sheller machine is used to shell only dry pods and it can be used as a groundnut Sheller machine for domestic application. It is a manual process where the groundnuts are removed from shell. The pedal is used for the movement of the crusher. There will be no energy consumption and the cost of production is less. It has less maintenance cost. It is very cheap and five experiments were performed with peanuts. Since this machine is made for small businessman or for farmers, therefore the work carried out by this machine is less. The decocting process of groundnut by this machine is more economical and faster than manual process or any other processes. Groundnut sheller machine will save the tremendous time, energy manpower and save financial input of the project, reducing the cost and time considerably which is the backbone of the present world economy. Done investigations on two manually operated decorticators and were tested and modifications done on one of the decorticators to optimize its technical performance. The performance tests showed that the requirements of the farmers including low kernel breakages and high shelling efficiencies could be achieved by the modified decorticator. Designed and fabricated a machine where sprockets of a bicycle are rotated by pedaling action and this rotary motion is used to rotate the shaft of a screw conveyor. The peanut gets crushed in between the flights around the shaft and the casing of the conveyor.

From our project using 1Hp electric motor and its has been operated by alternating current (Ac). To remove pods and shell.

ADEDEJI OMOTADE SEGUN, AJUEBOR FN **(2014)** reported that **PERFORMANCE EVALUATION OF MOTORIZED GROUNDNUT SHELLER**

"A power operated groundnutsheller that shells groundnut by mechanical shearing and cleans the shelled seeds from chaff pneumatically was designed, fabricated and tested. To increase the shelling efficiency and capacity and to reduce breakage of the seeds as well as reduce power consumption, certain modifications were carried out after the preliminary test. The modifications included a reduction in the shelling speed, rubberisation of the rotating beaters, optimization of the concave slots and adjustments in the blower speed. The modified machine was tested to evaluate its general performance. The best performance of the sheller was achieved at 260 rpm shelling speed, 30 mm – 40 mm concave clearance, feeding rate of 150 kg (pods)/h giving an output of 80 kg seed/h. The shelling efficiency, cleaning efficiency and breakage were 98%, 85%, and less than 5%, respectively. A blower speed between 1000 rpm – 1400 rpm is adequate for effective separation when chute sloped at 20° to the horizontal.

ASHISH S. RAGHTATE DR. C. HANDA (20014) reported that **DESIGN CONSIDERATION OF GROUNDNUT SHELLER MACHINE**

"Groundnut is grown on small scale farmers in developing countries like India. The average kernel price is approximately twice the price of pod. Lack of groundnut processing machines, especially groundnut Sheller, is a major problem of groundnut production, especially in our country India. A research-work for design, fabricate, and performance evaluation of a groundnut Sheller consisting of feed hopper with a flow rate control device, shelling unit, separating unit and power system. The performance of the machine was evaluated in terms of throughput capacity, shelling efficiency, material efficiency and mechanical damage. Regression models that could be used to express the relationship existing between the Sheller performance indices, pod moisture content and feed rate were establish. This paper describes about the design of various components of groundnut Sheller machine. Hence in this design of various parts are necessary, and design of various parts due to which the design quality of those parts will be improved.

Overall, this project involves processes like design, fabrication and assembling of different components etc.

KHARE G.N ET AL. **(2009)** reported that **DESIGN AND FABRICATION OF GROUNDNUT SHELLING AND SEPARATING MACHINE**

"Shelling is the removal of grains from their pod either by stripping, impact action and rubbing or any combination of these methods .The most popular method of groundnut shelling, which is still widely used is the method of crushing or pressing the pods in between the thumb and the first finger to break off the pods and release the seed. This method has low efficiency, it is time consuming, and has high demand of energy. Groundnut shelling machine is a machine used to remove the shell of groundnut so as to obtain the groundnut seeds. There are different machines have been fabricated and used to shell wide variety of groundnut pods .These machines are too costly and complex in operation and maintenance. The lowest price of the hand operated groundnut Sheller machine is Some of these machines have very high shelling capacity. Shelling capacity varies from machine to machine ranging from 5kg-seeds/h to 60kgseeds/h. Some hand operated Sheller machines are suitable for domestic application but they only do shelling operation, separation of seeds we have to do manually by using traditional methods such as by using natural wind or by using sieve. A simple hand operated groundnut Sheller has a semi-cylindrical screen closed on both sides. A shaft carrying a lever at one end is fixed across the centre of the semi-cylinder as shown in the on the lever is a pair of plate with shoes or beater bars, having blunts on their undersides. For successful operation of the machine, the operator stands by the side, then holding the operating lever (handle) and swinging it by pushing to and fro to provide shelling action on the shoes assembly. The semi-rotary, action of the shoes shells the pods against the screen but this type of machine.

From our project using 1Hp electric motor and its has been operated by alternating current (Ac). To remove pods and shell.

ARJUN VISHWAKARMA, TEJAS TANDALE (2009) reported that **DESIGN OF AN ELECTRICALLY POWERED GROUNDNUT SHELLING MACHINE**

"The machine was fabricated using materials that were easily available. It can be used for both household and industrial purposes. The advantage to be derived from the use of this machine overcomes its shortcomings. This design gives major advantages in the case of power consumption. The required power for above stated capacity is 1 hip while 1.98 as for conventional machine. Our designed machine is light weight compact and slim in construction. It is easy to operate and transport from here to anywhere. The bearing is used to all four shafts. It does not require percent lubrication. But it is suggested to lubricate bearing by oil periodically. The self-lubricated bearing can be used for shafts, but it will increase cost.

MR. ARJUN VISHWAKARMA, TEJAS TANDALE, PROF R. H.KEKAN (2009) reported that **DESIGN AND DEVELOPMENTOF A GROUNDNUT POD SEPARATING**

"Groundnut pods were separated from its crop by the workers. The output got from this method, was very low and it does not fulfill the market demand because it was very time consuming process. Our project mainly consists of robotic arm and spiked rotating drum. Robotic arm will pluck out the groundnut crop and feed it on the spiked rotating drum. Spikes on rotating drum will separate the pods from ground crop. There are big Groundnut Harvesters available in market, but farmers having small farm area can't afford that harvester. Our machine is small, lightweight, and low in cost. Farmers having small farm area can afford and use our machine capacity of shelling 400kg of groundnut per hour with a shelling and separating efficiencies of 95.25% and 91.67%respectively. The machine was fabricated from locally sourced materials, which makes it cheap and easily affordable and also easy and cheaper to maintain. It is also of light weight and comprises of the hopper, crushing chamber, separation chamber and the blower unit. During the process of testing, it was observed that majority of the groundnut pods that came out unshelled or partially shelled were the ones with one seed per pod and those with two small seeds in their pods.

WANGETTE ISAAC SIMIYU (2008) reported that **INFLUENCE OF GROUNDNUT AND MACHINE CHARACTERISTICS ON MOTORISED SHELLER PERFORMANCE**

"Groundnut shelling is a fundamental process in post-harvest management. Manual shelling is inefficient and laborious with low throughput. Motorised shellers experience less than 100% shelling efficiency and varying levels of kernel damage, hence, the need for optimization. Research work involving many factors require large numbers of experimental runs, resulting in high costs and are time consuming. Taguchi design of experiments enables to arrive at best parameter combination for optimal conditions with least number of analytical investigations. In this work, Taguchi method with S/N and ANOVA techniques were applied to optimize groundnut sheller performance involving the influence of six machine and groundnut factors on three output parameters. Best output results were obtained as follows: Throughput per unit power consumption of 921.03 (kg/h)/kWh at 12.2 m/s shelling speed, rubber paddle shelling blades, CG 7 variety, 6% mc, 1200 kg/h feed rate and 10 mm concave clearance. Shelling efficiency of 99.08% at 12.2 m/s shelling speed, rolling steel pipe shelling blades, Valencia red variety, 6% mc, 2000 kg/h feed rate and 10 mm concave clearance. Kernel mechanical damage of 1.25% at 7.4 m/s shelling speed, fixed rubber pipe shelling blades, Valencia red variety, 12% mc, 800 kg/h feed rate and 15 mm concave clearance.

ALONGE, A. F ET AL (2007) reported that **DEVELOPMENT AND PRELIMINARY TESTING OF A BAMBARA GROUNDNUT SHELLER**

"A centrifugal bambara groundnut pod shelling machine was designed and constructed to crack various sizes and varieties of bambara groundnut. The sheller was fabricated with locally available materials from the formation of a new idea which aimed at easing the pain, stress, intensive labour, time consumption, undue cost and the cumbersome operation encountered in the traditional method of shelling. The machine consists of three main units, namely the hopper, shelling unit and power transmission unit. The sheller uses impact technique and was designed to shell Bambara groundnuts effectively and also

to eliminate drudgery associated with the traditional methods of shelling legumes. Five hundred (500) samples of sundried Bambara groundnuts at 6% (wet basis) which were randomly selected were shelled at an impeller rotation speed of 1636 rpm. The results of the test showed that the shelling efficiency, seed damage, partially shelled pods, unshelled pods and the machine capacity were 83.2%, 17.4%, 7.8%, 9% and 75000 seeds/hr respectively.

From our project using 1Hp electric motor and its has been operated by alternating current (Ac). To remove pods and shell.

TUSHAR WALKE ET.AL **(2005)** reported that **DESIGNED AND FABRICATED THE GROUNDNUT MACHINE WHICH IS ELECTRICALLY OPERATED.**

"The working of the machine is power supplied to motor it rotates the roller. Groundnuts are supplied in crushing chamber through hopper and they get crushed between Semicircular net and the roller. Thus, the ground nuts are removed from the shell. The machine was fabricated using materials that were sourced locally. It can be used for both domestic and industrial purposes. The advantage to be derived from the use of this machine far outweighs its shortcomings. The test result showed that the machine can shell a total of 400kg of groundnut in an hour. Designed and fabricated the machine that has the capacity of shelling 400kg of groundnut per hour with a shelling and separating efficiencies of 95.25% and 91.67% respectively. The machine was fabricated from locally sourced materials, which makes it cheap and easily affordable and also easy and cheaper to maintain. It is also of light weight and comprises of the hopper, crushing chamber, separation chamber and the blower unit. The fresher and small farmer or business man can start business by investing less capital. Groundnut decorticator consists of feed hopper with a flow rate control device, shelling unit, separating unit and power system.

From our project using 1Hp electric motor and its has been operated by alternating current (Ac). To remove pods and shell.

TEJAS TANDALE, ARJUN VISHWAKARMA (2005) reported that **DESIGN AND FABRICATION OF GROUNDNUT DECORTICATOR**

"Groundnut is the 6th most vital oilseed trim on the planet. It contains 48-50 for every oil and 26-28 for each protein, and is a rich wellspring of dietary filaments, minerals and vitamins. It develops best on soils that are very much depleted, freely finished and well provided with calcium, potassium and phosphorous. More than 100 nations overall develop groundnut. Creating nations constitute 97 for every of the worldwide territory and 94 for each of the worldwide creation of this yield. The creation of groundnut is packed in Asia and Africa (56 for each and 40 for every of the worldwide zone and 68 for every and 25 for each of the worldwide generation, individually) Shelling is the expulsion of grains from their stalk, unit or whelp, either by stripping, affect activity and rubbing or any mix of these techniques. The most well known strategy for shelling which is still generally utilized as a part of the northern piece of Nigeria is the technique for pounding or squeezing the units between the thumb and the finger to sever the cases and discharge the seed.

KULBHUSHAN M. SHEJOLE, NITIN B. BORKAR, AND ABHIJIT M (2001) reported that **PEDAL OPERATED GROUNDNUT DECORTICATOR MACHINE**

"This paper deals with the pedal operated groundnut decorticator machine is better option to use farmer instead of hand operated. The machine is pedal operated so that there is no energy consumption which wills helps to reduce the cost of productions. This machine also saves time and manpower. If we go on continuous work we got a higher output in very short time. The operating procedure of this system is very simple, so there is no skill labour required to operate a machine. this produces an average mass of 3.43Kg of peeled roasted groundnut seeds, 0.462Kg of unpeeled groundnut seeds, 0.399Kg of partially peeled groundnut seed and 0.07Kg of broken groundnut seed. An average time of 488.8seconds and an average peeling efficiency of 78.46% was recorded. It was observed that the higher the mass of the roasted groundnut seeds the longer the time of peeling. The machine is cheap because the parts are locally fabricated. The technology could

provide employment and at the same time make available quality roasted groundnut seeds at low cost for domestic and commercial use in Nigeria.

DARSHAN GOWDA C P (2001) reported that **AUTOMATIC GROUNDNUT DECORTICATOR**

"Groundnut is the sixth most important oilseed crop in the world. Groundnut is a valuable source of edible oil (43-55%) and protein (25-28%) for human beings, and fodder for livestock. The major problem in groundnut production in country like India is the lack of groundnut processing machines available to farmers. In the beginning the peanuts were separated from its shells by the workers. The output from this method was very less and could not satisfy the market demand as it was very time consuming process. Numbers of groundnut Sheller machines are available in the market but they are large in size, costly and not suitable for domestic applications, they are best suitable for industrial applications where mass production is required. Hence it is essential to design and fabricate a portable groundnut decorticator machine for domestic application. In this project the process of designing the different parts of this shelling and separating machine considering all forces and ergonomic factor for people to use. The particular design of this project reduces all the causes and improves the efficiency. It consists of the hopper, crushing chamber, separation chamber, blower unit and the frame for support. The crushing chamber and blower unit is powered by electrically which save the time. The Output is about 20-25 kg/hour. The machine is also light weight, easy to operate and maintain.

From our project using 1Hp electric motor and its has been operated by alternating current (Ac). To remove pods and shell.

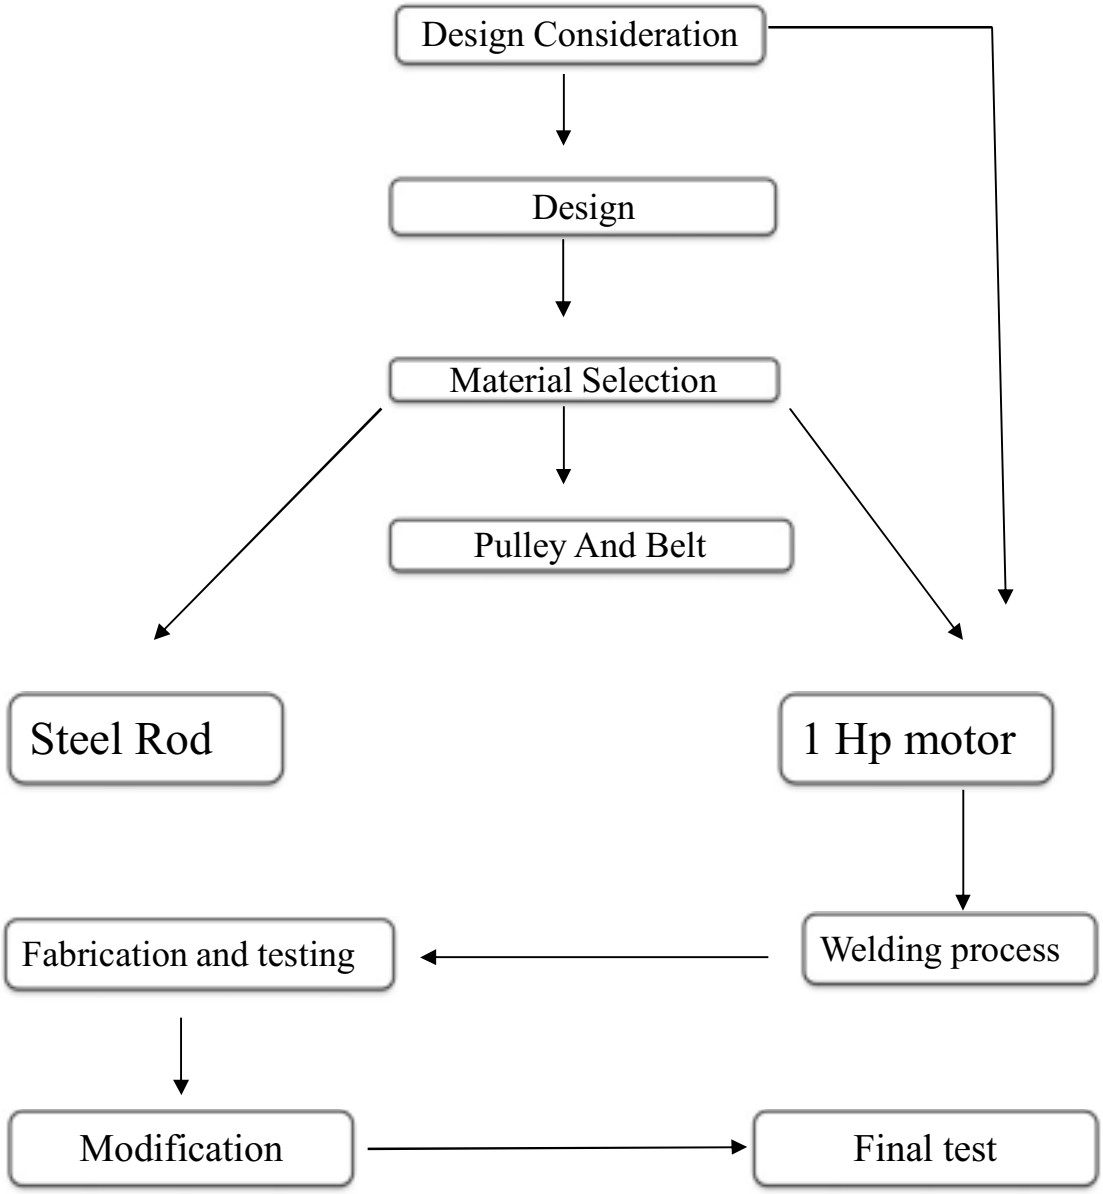
ROSHAN P GHODKHANDE, NILESH D DHOTE, (2000) reported that **DESIGN AND MODIFICATION OF GROUNDNUT DECORTICATOR**

"Decortications of groundnut is a tedious and time consuming process. Commercial available hand operated decorticators require more energy with less output. An attempt was made to develop and evaluate pedal operated groundnut decorticator. The study revealed that, the pedal operated decorticator gave an output of 25-30 kg/hr which was more than hand operated decorticator hand shelling. The difference in unit cost of operation for the unit was appreciably less than that of hand operated decorticator. By considering less fatigue to the operator and higher output, the pedal operated decorticator could be advantageously used for decortications of groundnut. Decortications of groundnut in which the pods is pressed between the thumb and first finger. This process is a "traditional methods". This method is mostly used in rural areas. This method is very tiresome. It has been observed that the efficiency and productivity with hand operated groundnut decorticator and the traditional method is less. Due to this tiresome working operation, Commercial available hand operated decorticators require more energy with less output. By considering this pedal operated groundnut decorticator is beneficial for decortications of groundnut pods.

CHAPTER 3

METHODOLOGY

3.1. FLOWCHART



CHAPTER 4

DESIGN ANALYSIS AND CALCULATIONS

4.1. DETERMINATION OF POWER REQUIRED TO BREAK THE GROUNDNUT PODS

Considering a single spike, the torque required to drive the system may be obtained from the following expression:

$T = n_a \times n_s \times F \times r$ (1)

Where,

n_a = number of active anchor at a time = 5

n_s = number of spike per anchor = 7

F = force per spike required to break the groundnut pod.

r = distance from the axis of rotation to the point of action of the force = 0.11m.

The average force required to break the groundnut pod is 2N. From equation (1), we get

T = 5 x 7 x 2x 0.11=7.7Nm

The power required in breaking the pods in the shelling chamber may be obtained from

$P = T \times \omega_2 = T \times \left[\frac{\pi \times N2}{30}\right]$ (2)

Where,

N_2= speed of rotation of the driven shaft = 240rpm

From equation (2), we get

$P = 7.7 \times \left[\frac{\pi \times 240}{30}\right]$

=193.32 W

4.2. DETERMINATION OF SPIKE DIAMETER

The loading on each spike is taken to be that of a concentrated intermediate load on a cantilever. Hence the deflection on it is

$$y = \frac{F \times a4}{8 \times E \times I}(a - 3 \times l) = \frac{64 \times F \times a4}{8 \times E \times л \times d4}(a - 3 \times l) \quad (3)$$

From equation (3), we get

$$d = \sqrt[4]{\frac{8 \times F \times a4}{E \times л \times y}(a - 3 \times l)} \quad (4)$$

Where,

d= spike diameter

y= deflection =-5×10^{-10} m

e= modulus of elasticity = 200×10^9 N/m^2

a= radius of the spike = 0.01

l = length of the spike = 0.02m

$$d = \sqrt[4]{\frac{8 \times 2 \times 0.01}{200 \times 109 \times л(-5 \times 10-10)}(0.01 - 3 \times 0.02)} = 2.99\text{m}$$

A diameter of 4mm was selected for use.

4.3. DETERMINATION OF PULLEY DIAMETERS

The diameters of the pulleys may be determined from the relation

$N1\ D_1 = N_2\ D_2$

$$\rightarrow \frac{N1}{N2} = \frac{D2}{D1} \quad (5)$$

Where,

N1 = speed of driving pulley = 1440rpm

N2 = speed of driven pulley

D1 = diameter of driving pulley = 0.04m

D2 = diameter of driven pulley

From equation (5), we get

$$D_2 = \frac{N1D1}{N2}$$

$$= \frac{1440 \times 0.04}{240} = 0.24\text{m}$$

4.4. DETERMINATION OF TENSION IN THE BELT

For a v-belt, the relationship between tension T1 and T2 in given by

$$2.3 \log \left[\frac{T1}{T2}\right] = \mu\theta\, cosec\, \beta \quad (6)$$

Where,

μ =coefficient of fiction between the belt and side of groove = 0.25

θ = angle of contact on the smaller pulley = 2.75rad

β = half angle of groove = 75

T_1 = tension on the tight side

T_2 = tension on the slack side

From equation (6), we get

$$\frac{T1}{T2} = \log^{-1}\left[\frac{\mu\theta \, cosec\, \beta}{2.3}\right] = \log^{-1}\left[\frac{0.25\times 2.75\times cosec\ 17.5}{2.3}\right]$$

$$\frac{T1}{T2} = 9.86 = T_1 = 9.86\ T_2 \quad (7)$$

Torque transmitted is given by

$$T = (T_1 - T_2) \times R_1 \quad (8)$$

Where,

T = torque transmitted

R = radius of pulley = 0.12m

From equation (8), we get

$$\frac{T}{R1} = 8.86\ T_2 = T_2 = \frac{T}{R1 \times 8.86} = \frac{7.7}{0.12 \times 8.86} = 7.24 \quad (9)$$

Substituting equation (9) into equation (7), we get

$T_1 = 9.86\ T_2 = 9.86 \times 7.24$

$T_1 = 71.39$ N (10)

4.5. DETERMINATION OF BENDING MOMENTS ACTING ON THE SHAFT

The forces acting on the shaft include: the weight of the crushing drum = 20N, the weight of the pulley attached to the shaft which drives the crushing drum, the resultant force effect of the belt tensions and the reactions at the bearings support. Fig. 1 shows the belt drive assembly.

$$F_V = T_1 \times \sin 8 \times \sin 29 + W_P = 17.45 \text{ N} \quad (11)$$

$$F_H = T_1 \times \cos 8 \times T_2 \times \cos 29 = 77.03 \text{ N} \quad (12)$$

Where,

F_V = vertical load effect of the belt drive assembly

F_H = horizontal load effect of the belt drive assembly

W_P = weight of the crusher pulley = 4N

Summing forces in the vertical direction gives

$$R_{AV} + R_{CV} = 20 + 17.45 = 37.45 \text{ N} \quad (13)$$

Taking moment about

$$R_{CV} \times 0.28 = 17.45 \times 0.34 + 20 \times 0.14$$

$$R_{CV} = 31.19 \text{ N}$$

From equation (13), we get

$$R_{AV} = 37.45 - R_{CV}$$

$$R_{AV} = 37.45 - 31.19 = 6.26 \text{ N}$$

From

$M_{AV} = 0$ Nm

$M_{BV} = 6.26 \times 0.14 = 0.88$ Nm

$M_{CV} = 6.26 \times 0.28 - 20 \times 0.14 = -1.15$ Nm

$M_{DV} = 6.26 \times 0.34 - 20 \times 0.20 + 31.19 \times 0.06 = 0$ Nm

Summing forces in the horizontal direction gives

$$R_{AH} + R_{CH} = 77.03 \text{ N} \quad (14)$$

Taking moment about

$R_{CH} \times 0.28 = 77.03 \times 0.34 = R_{CH} = 93.54$ N

From equation (14),

$R_{AH} = 77.03 \text{ N} - R_{CH}$

$R_{AH} = 77.03 \text{ N} - 93.54 = -16.51$ N

From

$M_{AH} = 0$ Nm

$M_{BH} = -16.26 \times 0.14 = -2.31$ Nm

$M_{CH} = -16.26 \times 0.28 = -4.65$ Nm

$M_{DH} = -16.26 \times 0.34 - 20 + 93.54 \times 0.06 = 0$ Nm

Resultant bending moment at A

$M_A = \sqrt{(MAV)2 + (MAH)2} = 0\text{Nm}$ (15)

Resultant bending moment at B

$M_B = \sqrt{(MBV)2 + (MBH)2} = 2.47\text{Nm}$ (16)

Resultant bending moment at C

$M_C = \sqrt{(MCV)2 + (MCH)2} = 4.74\text{Nm}$ (17)

Resultant bending moment at D

$M_D = \sqrt{(MDV)2 + (MDH)2} = 0\text{Nm}$ (18)

From equation (17), the maximum bending moment occurs at C with a value of 4.74Nm

4.6. DETERMINATION OF SHAFT DIAMETER

For a solid shaft having little or no axial loading, the shaft diameter may be determined from the following ASME code equation

$$D^3 = \frac{16}{\pi \tau Max} \sqrt{(kb\ Mb)2 + (kt\ Mt)2} \quad (19)$$

Where,

D = Shaft diameter

τ_{Max} = Permissible shear stress

M_b = Maximum value of bending moment

Mt = Maximum value of twisting moment

Kb= Combined shock and fatigue factor applied to bending moment

Kt= Combined shock and fatigue factor applied to twisting moment

The maximum permissible shear stress may be taken as42 MPa for shafts with allowance for keyways. For suddenly applied load, and. From equation (19), we get Kb= 0 .2 Kt=1.5

$$D = \sqrt[3]{\frac{16}{\pi \times 42 \times 10} 6\sqrt{(2.0 \times 4.74)2 + (1.5 \times 7.7)2}}$$

D = 12.19mm

A standard size of 25mm was selected.

4.7. DETERMINATION OF POWER TO DRIVE THE FAN

The power required to drive the fan may be obtained from the following expression

$$P_F = \frac{Q \times Ps}{\eta} \quad (20)$$

Where,

F_P = power required to drive the fan

Q = fan flow rate = 0.11m3/s

P_S = static pressure of fan = 336N/m2

η= static efficiency of fan = 75%

From equation (20), we get

$$P_F = \frac{Q \times Ps}{\eta}$$

$$P_F = \frac{0.11 \times 336}{0.75}$$

P_F = 49.28 W

The total power required by the machine = 193.52+49.28 = 242.8W, a 1hp electric motor was selected.

4.8. DESIGN CALCULATIONS

According to he motor specifications: voltage: 220-260 volts Current amp): 2 amps RPM: 1400 Capacity: 1 HP

Power:

P = VI

P = 240 X2
P = 480 Watt

We know that P = 2лNT/60

T = P X60 /2πN
T_{SHAFT} = 480X60/2л1400

T = 3.27 N-m

Energy consumption

E IN KWH = P X TIME
= 480 X 24
= 11520 W-hour/ day
= 11.52 kw- hour/day

For month,

= 11.52x 30 kw-hour/months

= 345.6 kw-hour/month

1-unit cost is 8.5 rupees

= 345.6 x 8.5 = 2937.6 /- per month.

Shaft calculations:

We have diameter of hollow shaft as follows

Outer diameter= 40mm

Inner diameter = 38mm

The shaft experienced with two moments bending moment as well as twisting moment.

$T/J = \tau/R$

We know that T = 3.27 N-m= 3270 N-mm

$J = л/32 ((D0)^4-(DI)^4)$

$= л/32 ((40)^4- (38)^4) = 46619.7$ mm4

$=3270/46619.7 = \tau/20$

$\tau_{shaft} = 3270x20/46619.7 = 1.4$ N/mm2

Bending stress = $M/I = \sigma/Y$

Bending stress due to self-weight = 5kg

Weight = 5x9.81 = 49.1 N

Stress (σ) = P/A

$\sigma = 49.1/ (л/4) ((40)^2-(38)^2)$

$\sigma = 0.4$ N/mm2

For circular shaft: $I= л/64 ((D0)^4-(DI)^4)$

$$I = \pi/64 ((40)^4-(38)^4) = 23309.83 \text{ mm4}$$

Bending moment (M) = (σ X I)/Y

$$M = (0.4X\ 23309.83)/20 = 466.197 \text{ N-mm}$$

Shaft subjected to combined torsion and bending:

$$\tau_{max} = (16 \times d_0 / \pi((d_0)^4 - (d_i)^4)) (M)^2 + (T)^2$$

$$= (16X40X3303.1)/\pi ((40)4-(38)4)$$

$$\tau_{max} = 1.41 \text{N/mm2}$$

$$\sigma_{max} = (16 \times d_0 / \pi ((d0)^4 - (di)^4)) (M+ (M)^2 + (T)^2)$$

$$= 16X40\ X\ (3769.3)/ \pi ((40)^4-(38)^4)$$

$$\sigma_{max} = 1.62 \text{ N/mm2}$$

4.9. DESIGN OF THE EQUIPMENT

4.9.1. DESIGN OF FRAME

We considered the frame of height of 3m and we kept shield around it so that the groundnut pods which move in random direction does not go out. The complete design can be viewed in fig 4.9.1.1

Fig 4.9.1.1. Design of Frame

4.9.2. DESIGN OF ROLLER AND SHAFT

We designed a rotor with the help of hollow shaft of diameter 4 cm and length of 48 cm. We also kept flat mild steel plate on four sides of the hollow shaft. The flat plat which we considered is of length 30 cm and thickness of 5mm. Curved plates is welded on the flat plates with the help of arc welding. This rotor helps to break the ground nut pods. Due to shear force between rotor and ground nut pods the shell of the pods breaks. The figure 2 shows the design of shaft and figure 3 shows the rotor complete design.

Fig 4.9.2.2. Roller

Fig 4.9.2.3.Shaft

4.9.3. DESIGN OF COMPLETE EQUIPMENT

The complete equipment is shown in the figure 4. We assembled the rotor and cycle rim and a slope which can be seen in the figure. The slope is of at an inclination of 45 degrees.

Fig 4.9.3. Complete Design

CHAPTER 5

COMPONENTS AND SPECIFICATIONS

- Frame
- Electric motor
- Roller
- V-Belt
- Pulley
- Hopper
- Fan
- Semicircular Net
- Input shaft
- Fork
- Output shaft

5.1. FRAME

The frame is used to support all the components. Material of frame is cast iron and height up to 1m.

Fig 5.1. Frame

5.2 ELECTRIC MOTOR

The motor is a solitary stage air conditioning commutators motor, 1hp power implying that the speed is endlessly 1440 rpm. The motor is mounted on the base plate and is associated with the information shaft by methods for a v belt.

Output = 230 volt

Current =7amps

Power =0.74kw/1 HP

Fig.5.2. Motor

5.3 ROLLER

Roller is made up of hollow cylinder of 1ft dia. and 1ft length with the rods welded on its periphery. The material of roller is cast iron.

Fig.5.3 Roller

5.4 V-BELT

V-Belt is used to transmit rotary motion of shaft of motor to the shaft of roller. Material of the belt is rubber or polymer for strength and reinforcement.

Fig .5.4. Belt

5.5 PULLEY

Pulley is used to transmit the torque of motor to the roller. One pulley is directly mounted over the motor shaft and another pulley mounted on the shaft of roller. And both the pulleys are connected with the help of V-belt. Pulley Dia. =75mm.

Fig .5.5. Pulley

5.6. HOPPER

Hopper contains groundnuts before and during shelling process. It is use to continuous supply of the groundnut to the crushing unit.

Fig 5.6. Hopper

5.7 FAN

Fan is mounted on the shaft of the motor just in front of pulley at some distance. This fan separates the shell and the peanuts.

5.8. INPUT SHAFT

The info shaft is held in metal ball upheld in the focal bearing piece. The info shaft conveys decrease pulley at one end while the info wrench at the flip side. The information wrench is settled on the info shaft and conveys the fork at the flip side.

Fig.5.8. Input Shaft

5.9. SEMICIRCULAR NET

This semicircular net is fitted beside the roller at very small distance so that shell of groundnut should be easily cracked and peanuts remain uncracked.

5.10. FORK

The fork is associated with the information wrench toward one side where as it is associated with the output shaft at the flip side by means of fork stick.

5.11. OUTPUT SHAFT

The output shaft is a vertical part which is upheld in two brambles bearing an either closes that are held in appropriate bearing squares. The game plan changes over clockwise turn of output shaft. This course of action changes over clockwise turn of yield when information shaft. This game plan changes over clockwise pivot of yield when info shaft turns frame 0 to 180 degrees, yet amid this operation or movement transformation the yield likewise moves in the pivotal bearing, Which needs to be compelled, which should be obliged, subsequently a spring is fused in the set up.

5.12. TRANSMISSION

The mechanical power delivered by prime mover we used to drive different machines in the workshop and plants. A transmission framework is the system, which manages transmission of the power and movement from prime mover to shaft or, then again from one shaft to the next. The machine apparatus drive is a total of component that transmits movement from an outside source. To the agent components of the machine device the outside wellspring of vitality is for the most part a three stage A.C. engine, which has a rotating movement at its yield shaft. The revolving movement of the engine is transmitted to the agent component to give an agent working or assistant movement. At the point when the required movement is revolving; the transmission happens through instruments that exchange Rotating movement starting with one shaft then onto the next. Transmission of the movement from the outside source to the agent component can occur through Mechanical components, for example, belts, Riggings, chains and so on.

5.11. MECHANICAL TRANSMISSION AND ITS COMPONENTS

5.12.1. Belt Transmission

5.12.2. Gear transmission

5.13.3. Chain Transmission

5.12.1. BELT TRANSMISSION

Belt drive is a standout amongst the most widely recognized viable gadgets transmitting movement and power from one shaft to the next by methods for thin inextensible belt over running over to pulleys. This to a great extent utilized for broadly useful on plants and production lines particularly when the separation between the Poles is not exceptionally awesome. At the point when the inside separation between the two shafts is extensive than the tight side of the belt ought to be the lower one the pulley called driver is mounted on the driving shaft while the pole while the other, which is mounted on the pole to which power is to be transmitted is known as the determined pulley or devotee. At the point when the belt moves over the pulleys there is dependably the plausibility of slipping between the belt and pulley and hens the character of the movement transmitted is not positive when positive activity is required. Riggings and chain must be utilized.

5.12.2. GEAR TRANSMISSION

Proficiency of energy transmission in belt and rope drives is less. The power might be transmitted from one shaft another by methods for mating gears with high transmission Effectiveness and a rigging drive is additionally give when the amongst driver and devotee is little.

5.12.3. CHAIN TRANSMISSION

Chains are utilized for high transmission number. They are for the most part utilized when separation between focus is short yet the middle separation is as much as 8m. They are currently for the most part utilized for transmission of energy in cycle, engine vehicle, and farming hardware in workshops. It is general necessity for any machines that they ought to arrangement for managing velocity of travel. The direction might be accessible in discrete strides or it might be steeples i.e. ceaseless. The

configurations are known as ventured drives Ex. Machine, processing machine, printing machine and so forth.

5.13. FUTURE EXTENSION

The agribusiness is the fundamental calling of immense of populace around the world .A few changes should be possible in this machine also. It will be utilized over long scale. This machine gives better help to ranchers with the goal that they can get appropriate salary of their harvest. The degree in rural field is gigantic. It will be a limitless segment to deal with to limit man control and enhance effectiveness of operation, reduction cost of operation, lessening endeavors. The world is developing so quickly and all need sound sustenance for solid life. This sustenance originates from agribusiness. So the yield dealing with strategies ought to be effective to keep it sound. The new developments in farming field won't just offer assistance agriculturist additionally advantageous to satisfy request by not bringing on value climb.

5.14. WORKING PRINCIPLE

By utilizing electrical motor, the pivoting minute exchanged with the assistance of belt to the rotor shaft and fan shaft. The progression pulley is kept up on the electrical motor shaft. At the point when rotor turning the groundnut falls in the container and afterward groundnut squeezed between the rotor and flame broil. Around then groundnut seed and case isolated. The groundnut case and groundnut seeds fall in the plate. Because of high fan speed the high speed of air is made by utilizing this high speed air the light weight unit is tossed out from the machine and the groundnut seed falls in the plate because of this weight. We gather the seeds in the pot of pack.

CHAPTER 6

ADVANDAGES

- To reduce time consumption
- To reduce the cost of machine
- To speed up the process
- Maintenance cost very low.
- Easy to handle the farmer.
- The machine should not have high weight. It should be easily move anywhere.

CHAPTER 7

RESULTS AND DISCUSSIONS

The various parts of the machine were assembled, after which the electric motor was mounted, the machine was then test run without groundnut poured into the hopper. This was done to study the behaviour of the machine. Fig. 4 shows the electrically powered groundnut shelling and separating machine. Test was then carried out to evaluate the performance of machine based on its shelling efficiency, the time taken to shell a known weight of groundnut pods and the capacity of the machine. The shelling efficiency was assessed by taking four separate experimental samples of 100 groundnut seed poured into the hopper while the machine was running. After each group was passed through the machine, the output was analyzed by physically counting the shelled, unshelled, partially shelled, broken or shattered groundnut. The sum of the shelled and shattered groundnuts makes up the shelling efficiency.

TABLE 1 Test results for shelling efficiency

Test	Separating and Deshelling (Numbers)	Un Separating and Deshelling (Numbers)	Partially (Numbers)	Shattered (Numbers)	% Separating and Deshelling
1	30	5	13	17	47
2	35	5	7	18	54
3	30	8	6	16	50
4	36	3	5	16	60

The shelling efficiency of the machine was calculated as follows

Average number of groundnut shelled $= \frac{30+35+30+36}{4} = 33$

Average number of groundnut shattered $= \frac{17+18+16+16}{4} = 17$

Therefore, shelling efficiency of the machine $= (\frac{33}{100}+\frac{17}{100}) \times 100 = 50\%$

The separation efficiency was determined by shelling two sets of groundnut and re-weighing after shelling. Table 2 shows the test results for the separation efficiencies.

TABLE 2 Test results for separation efficiency

Test	Initial weight(kg)	Final weight(kg)	Final weight(kg)	Separating efficiency (%)
1	0.6	0.52	0.08	$\frac{0.52}{0.6} \times 100 = 86.67$
2	0.6	0.58	0.02	$\frac{0.58}{0.6} \times 100 = 96.67$

Therefore, separation efficiency $= \frac{86.67+96.67}{2} = 91.67\%$

During the test, to determine the capacity of the machine, it was observed that it took 54 seconds to shell 6kg of groundnut. It then means that in one minute, one can shell o total of 6.7kg of groundnut and in 1 hour, a total of 400kg of groundnut can be shelled. It was also observed that groundnut with one seed per pod were the ones that came out unshelled or partially shelled. Others that also came out unshelled or partially shelled were the ones that had two small seeds in their pods

CHAPTER 8

CONCLUSION

1. This work presents the design of an electrically powered groundnut pods stripper and shelling machine.
2. It can be used for both domestic and industrial purposes.
3. The advantage to be derived from the use of this machine far outweighs its shortcomings.
4. It was also observed that groundnut with one seed per pod and those with two small seeds in their pods were the ones that came out unshelled or partially shelled.

COST ESTIMATION

Steel Rod	Rs 500
1HP motor	Rs 1500
Belt and pulley	Rs 500
Hopper	Rs 800
Welding cost	Rs 500
Roller	Rs 900
Bearing	Rs 300
Total	Rs 5000

ACKNOWLEDGEMENT

We are very much grated thankful to our faculty Mr. K. VISHNU BHARATH M.E Head of the Agriculture Engineering Department for providing the support and guidance towards this work.

ABSTRACT

In this project we are using three flower crops such as Ixora coccinea, chrysanthemum and crossandra under polyhouse cultivation. The temperature, relative humidity and ventilation of air are controlled by the equipments fixed in the polyhouse. Crops grown in the polyhouse are protected from intense heat, bright sunlight, strong winds, hailstones and cold waves. They are grown in two different mediums such as vermiculite and perlite. It is grown by using different treatments like hydrogen peroxide, growth hormone compared with normal growth of the flowers. The effect of the solutions and the mediums are observed. The root elongation and the shoot development of the flowers enhance the development of the flower. Various mediums help the flower growth in the developing periods and the blooming of the flowers is collected. Gibberellin is used as growth hormone that regulates the stem elongation, flower development.

KEY WORDS: Gibberllic acid, hydrogen peroxide, vermiculite, perlite.

CHAPTER 1

INTRODUCTION

1.1 GENERAL

With globalization of markets, shrinking land and climate change, the protected cultivation of high value crops has emerged as the single most important technology for ensuring high productivity, improved quality and profitable returns. A technique wherein the microclimate around the plant is controlled fully, partially or modified to protect the crop from adverse weather protected cultivation ensures conservation of soil moisture and efficient use of energy mainly solar. The need for protected cultivation are higher yield, better quality, off-season production, controlled pollination, easier plant protection, weed free cultivation and year round cultivation.

1.2 FLOWER CROPS

The flower crops are chrysanthemum, crossandra and ixora coccinea. They are grown in different mediums.

1.2.1 CRYSANTHEMUM

The chrysanthemum is important ornamental crop mainly grown for the production of cut flowers, loose flowers and pot plants. The plant belongs to family Asteraceae and is popularly known as "Queen of the East". The utility and popularity of chrysanthemum have increased recently with the introduction of new cultivation technique "year round production of chyrsanthemums" based on scientific work conducted in the field of plant physiology photoperiodism and genetics.

1.2.2 CROSSANDRA

It is one of the famous and an important commercial flower crop cultivated throughout India. This flower is also called as "fire cracker flower". This flower is popularly known as "kanakambaram" in south India. The flower is also grown in countries like tropically areas of Africa and Madagascar. This flower becomes popular in India due to its bright attractive color and light weight. These flowers are used for woman hair adornment and making garments. Normally women mix these flowers with jasmine flowers and use them as hair adornment. Crossandra belongs to Acanthaceae.

1.2.3 IXORA COCCINEA

Ixora is said to be native to Asia and whose name derives from an Indian deity. There are about 400 species spread from Africa to India to Southern Asia. They differ in leaf size, plant height, and flower size and flower color. This plant which blooms throughout the year is easy to grow. The flowers are found in a wide range of colors. Ixora flower has traditionally been associated with enhanced sexuality and the rekindling of passion.

1.3 IMPLIMENTATION

The project is experimented at the polyhouse cultivation in an enclosed environment. The plant growth is carried out in an area in which the temperature and relative humidity are maintained. The flower crops such as ixora coccinea, crossandra and chrysanthemum are grown in two different mediums such as perlite and vermiculite with the application of hydrogen peroxide and growth hormone such as gibberellin are done. The observations of their growth is measured and calculated in different days and their effect is observed by their flowering. The crop growth is maintained under a period of time. The solid medium of which are solid in nature. Planting with soilless potting mix does not include the use of soil. Instead, plants are grown in a variety of organic and inorganic materials. Using these materials rather than soil allows growing healthier plants without the threat of soil-borne diseases. Growing hormones are those chemical signals that coordinate the different parts of an organism. Hormones in plants act I similar ways. They are produced by cells in one area of the plant such as the leaves, stems or root and then transported to a different area of the plant in order to produce a response.

Gibberellins are hormones produced in meristem of stems and roots that help regulate stem elongation. This group of hormones is actually named after a fungus caused some rice plants to unbelievably tall event to the point where rice plants would follower because the stem was too tall for the roots to support. Like that we are using gibberellin for the growth of the flower crops. Hydrogen peroxide is made up of the same atoms that water is made from with the exception of an additionally oxygen atom that extra oxygen gives hydrogen peroxide. It helps encourage healthy root growth because of the extra oxygen molecule. Oxygen can help plant roots observe nutrients from the soil. Therefore this extra bit of oxygen better enables the root to absorb the more nutrients which means faster healthier more vigorous growth. We are estimating the growth difference among various treatments in different flowers. The growth of the three flowers are monitored and observed in different operations and their plant height, number of leaves, stem height, leaf length are analyzed.

FIGURE 1.1 GREENHOUSE

1.4 OBJECTIVES

- To determine the quality of solutions in flower crops by using different treatments.
- To analyze the growth difference using different mediums.
- To evaluate the growth in different applications.

CHAPTER 2

LITERATURE REVIEW

Xu Gizhong, Chen Haijiang, Ma Baokun, Lhang Wencai (2001) *entitled as* **"EFFECT OF EXOGENOUS SPERMIDINE ON FLORAL INDUCTION, ENDOGENOUS POLYAMINE AND HORMONE PRODUCTION, AND EXPRESSION OF RELATED GENES IN 'FUJI' APPLE"** said Flower bud formation in 'Fuji' apple (*Malus domestica Borkh.*) is difficult, which severely constrains commercial production. Spermidine (Spd) plays an important role in floral induction, but the mechanism of its action is incompletely understood. To investigate the effect of Spd on flowering, 6-year-old 'Fuji' apple trees were treated with 1×10^{-5}mol L^{-1} Spd to study the responses of polyamines [putrescine (Put), Spd and spermine (Spm)], hormones [gibberellins (GA_3) and abscisic acid (ABA)], and polyamine hormone and flowering related genes. Spd application promoted flowering during floral induction by increasing *MdGA2ox2* (*gibberellin 2-oxidase*) through GA_3 reduction and increasing *MdNCED1* and *MdNCED3*(*9-cis-epoxycarotenoid dioxygenase*) through ABA enrichment during 60 to 80 days after full bloom. The flowering rate as well as the expressions of flower-related genes, except for *MdLEY* (*LEAFY*), also increased, thereby promoting flowering. In addition, spraying with Spd significantly increased the contents of endogenous polyamines except for Spm in terminal buds by increasing the expressions of polyamine-associated genes. We hypothesize that the contribution of Spd to flowering is related to crosstalk among polyamines, hormone signals and related gene expressions, which suggests that Spd participates in the apple floral induction process.

From this we have taken the concept of using the gibberellin in flower crops in two different mediums in which they increased and promoting flowering and increases the shoot development and increases the flower buds and their production in flowering.

H Emami, M Saeidnia, A Hatamzadeh, D Bakhshi, E Ghorbani (2011) *entitled as* "**THE EFFECT OF GIBBERELLIC ACID AND BENZYLADENINE IN GROWTH AND FLOWERING OF LILY (*Lilium longiflorum)*"** said in order to study growth and flowering characteristics of Lilium longiflorum by using tow growth regulators, gibberellic acid and 6-benzyladenine, an experiment was performed in 2008 by using factorial experiment arranged in a completely randomized design with three replication in research greenhouse, college of agricultural science, University of Guilan. In this experiment, unit bulbs soaked for 24 hours by gibberellic acid and 6-benzyladenine, and then they planted in greenhouse. Results showed that the maximum bud number was relateda to gibberellic acid 150 ppm with benzyladenine 75 ppm. The highest chlorophyll a content was related to gibberellic acid 75 ppm with benzyladenine 75 ppm, gibberellic acid 75 ppm and benzyladenine 75 ppm respectively. In addition, the highest total chlorophyll achieved when we used gibberellic acid 75 ppm with benzyladenine 75 ppm. The highest initial fresh weight was related to gibberellic acid 75 ppm. Gibberellic acid 75 ppm, benzyladenine 150 ppm and benzyladenine 75 ppm showed the maximum anthocyanin content respectively. The maximum vase life was related to gibberellic acid 75 ppm. In order to achieve qualification, longevity of vase life and economic aims, we suggested using gibberellic acid 75 ppm with 6-benzyladenine 75 ppm.

From this we have taken the idea of using gibberellin in a proper ratio of floral bud and root elongation. In another treatment we are using the hydrogen peroxide for the strong root growth. The longevity of vase life and the bud number is getting increased.

Brintha Karunarathna and Kumuthini D Harris (2016) *entitled as* "**EFFECT OF COCONUT WATER ON THE CUTTING ESTABLISHMENT OF IXORA (IXORA COCCINEA L.)**" said an experiment was carried out to study the effect of coconut water on cutting establishment of Ixora (Ixora coccinea) at the shade house of Crop Farm, Eastern University, Sri Lanka during the period February 2016 to May. The experimental was laid out in Complete Randomized Design (CRD) replicated thirty times.

The treatments were: coconut water treatment (T1) and without coconut water treatment (control T0). The poly bags were filled with top soil: red soil: cow dung at the ratio of 1:1:1 and leaving 1 inch at the top for watering. The uniform cuttings were selected.The cuttings were taken in the early morning and the cutting ends were kept in water prior to planting to keep the

cuttings turgid. Then the cuttings were planted into the prepared poly bags and labeled. Coconut water was collected in a clean bucket in the early morning. Once in five days, 100 ml coconut water was poured into the bags (T1). The results suggest that, length of roots (52 %), the number of roots (63 %) and root initials (70 %) plant height (28 %), number of branches (44 %) and number of leaves (70 %) increased with the application of coconut water to the cuttings. Therefore, under the conditions of this experiment, establishment ability is high when the cutting treated with coconut water. This is one of the cheapest ways to induce number of roots and shoots in Ixora. Roots are used for stomach troubles and dysentery, treatment for bloodshot eyes, sores and ulcers. Ixora is a moderate to root plant species and rooting ability is moderate under natural conditions.

There were significant differences ($P < 0.05$) in the length of the longest root between coconut treated cuttings (T1) and the control (T0) (Table 1). Also, 95% confidence intervals (1.413, 3.521), (1.471, 3.530) and (16.644) confirms that there is the difference between coconut water applied cuttings and the control. The average length of roots in T1 and T0 were 11.09, 8.63 at 30 DAP, 14.75, at 45 DAP and 23.50, at 60 DAP. This might be due to the effect of cytokinins, auxin present in coconut water. Therefore, it is evident that Cytokinins and IBA present in the coconut water stimulated the formation of masses of undifferentiated cells (callus). The callus cells are then induced to form roots as a result of exposing them to certain hormones like auxins (in the coconut water) that produced roots.

This increase in root length also may be due to the effect of growth regulators IBA on the metabolites translocation and carbohydrates metabolism. Rout (2006) observed that IBA produced a higher yield of roots in Camellia sinensis compared to the other auxins. This result is inconsistent with the studies of Okunlola (2016) who reported that rooting hormones applied wood cuttings of Bougainvillea spectabilis had a significant effect on length of roots compared to that of control.

Average length of longest root (cm) at 30, 45 and 60 DAP Average root length (cm) 30 DAP 45 DAP 60 DAP value P value Number of roots and root initials per cutting. The number of roots per cutting is given in Table 2. Coconut treated cuttings had a significant effect on a number of roots per cutting. At 30, 45 and 60 DAP, the higher percentage of roots per cutting

was recorded (77%, 32% and 63% respectively) in those cuttings treated with coconut water than in control.

The concept of using gibberellic acid and hydrogen peroxide using in flower crops and their growth is increased by applying them for a certain period of time. The flowers production will be more in number and their elongation is formed.

Tariq Saeed, Imran Hassan, Nadeem Abbasi (2014) *entitled as*"**EFFECT OF GIBBERELLIC ACID ON THE VASE LIFE AND OXIDATIVE ACTIVITIES IN SENESCING CUT GLADIOLUS FLOWERS**" saidcut flowers face the problem of short display life and lose their aesthetic value rapidly. In order to enhance the vase life of gladiolus, its cut spikes were subjected to different levels of gibberellic acid (GA3), viz., 0, 25, 50, 100 and 200 mg L−1 in vase solution, during two consecutive years 2010 and 2011. The GA3 treatment significantly influenced the vase quality attributes and antioxidants capacity of gladiolus cut flowers. Gibberellic acid at 25 mg L−1 caused the longest time taken to open the floret and increased the floret opening, vase life duration and fresh weight. The highest anti oxidative activities of superoxide dismutase and free radicals scavenging were also recorded with GA3 at 25 mg L−1. The highest peroxidase, catalase activity and the lowest membrane leakage were recorded with GA3 at 50 mg L−1. Present study concludes that GA3 applied at lower concentrations (25 mg L−1) renders greater beneficial effects on vase life quality, membrane stability and antioxidant activities in gladiolus cut spike, and further higher application rates because no improvement in the flower longevity compared with control.

From this we are using gibberllic acid in three types of flowers crops are crossandra, chrysanthemum and ixora coccinea to reduce early senescence instead of using in gladiolus flowers.From this we have taken the idea of using vermiculite and perlite in flower formation and root elongation in the flower crops.

Margit Olle, MahieuNgouajio, Anastasios Siomos (2012)*entitled as***VEGETABLE QUALITY AND PRODUCTIVITY AS INFLUENCED BY GROWING MEDIUM** saidthe aim of the review is to present an overview of the effects of mineral soil, inorganic and organic growing media on the growth, development, yield and quality of vegetables grown under greenhouse conditions. The findings from the literature suggest that the yield of various vegetables tends to be higher for the plants grown in various growing media compared to those grown in the soil. A number of authors have reported that dry matter, sugar, soluble solids, vitamins and carotenoids content in tomatoes; acidity and taste have better marks when grown in soilless culture systems compared to soil. Only very few authors have indicated that soil culture could increase acidity, dry matter, carotenoids and sugar content in tomatoes compared to soilless culture systems. Growth and development of vegetables are enhanced, when plants are grown in inorganic media compared to organic ones. For yield enhancement several authors have recommended growing vegetables in inorganic media (rockwool, sand) rather than organic media. Furthermore, there is a growing body of studies indicating the benefit of mixing organic and inorganic components for vegetable growing media with improved performance in greenhouse production. In most cases, the addition of compost did not change the yields of vegetables grown on organic media. Also it is difficult to draw broad conclusions on the impact of various organic substrates on the chemical composition of vegetables based on the information in the literature. Some inorganic substrates can influence growing medium so that vegetables grow faster, but that may depend on substrate used. As a substrate, zeolite had advantages over perlite, as it increased growth of crisp-head lettuces. As observed with organic media, it is difficult to draw general conclusions on the impact of inorganic media on the chemical composition of vegetables.

From this we are using different mediums like perlite and vermiculite in flower crops for their root and bud formation and their growth in their application.

Guihong Bi, Williams B Evans, Glenn B Fain (2009) *entitled as* **"USE OF PULP MILL ASH AS A SUBSTRATE COMPONENT FOR GREENHOUSE PRODUCTION OF MARIGOLD"** saidPulp mill ash was evaluated as a substrate component in the production of greenhouse-grown French marigold (*Tagetespatula* L. 'Janie Deep Orange'). Peat-based substrates (75:10:15 by volume blend of peatmoss, vermiculite, and perlite) amended with 0% to

50% (by volume) pulp mill ash were compared with a standard commercially available substrate. With the exception of an unfertilized control, each substrate blend contained 5.93 $kg \cdot m^{-3}$ 14N–6.2P–11.6K (3- to 4-month release) and 0.89 $kg \cdot m^{-3}$Micromax. Substrates containing higher volumes of ash had finer particles, less air space, and more waterholding capacity than the commercial substrate. Bulk density increased with increasing ash volume, and substrate containing 50% ash had 120% greater bulk density than the commercial substrate. Substrates containing ash generally had higher pH and electrical conductivity (EC) than the commercial substrate with substrate pH and EC increasing with increasing ash volume. In general, marigold plants grown in peat-based substrates with the addition of 0% to 50% ash had similar growth indices, flower dry weights, numbers of flowers, and SPAD values as plants grown in commercial substrate; however, plants grown in substrates containing 30% to 50% ash had lower shoot dry weights or root quality ratings than plants grown in commercial substrate. Plant growth index, shoot dry weight, and root quality rating decreased with increasing ash volume and availability of elements of the inorganic substrate.

From this we have taken the idea of using the floral bud formation in applying the gibberllic acid and hydrogen peroxide in for their growth and elongation of shoot and root formation.

SL Sukanya, J Sudisha, P Hariprasad, SR Niranjana, HS Prakash, SK Fathima (2009) *entitled as*"**ANTIMICROBIAL ACTIVITY OF LEAF EXTRACTS OF INDIAN MEDICINAL PLANTS AGAINST CLINICAL AND PHYTOPATHOGENIC BACTERIA"** said the ethnobotanical efficacy of Indian medicinal plants; Achyranthes aspera, Artemisia parviflora, Azadirachta indica, Calotropis gigantean, Lawsonia inermis, Mimosa pudica, Ixora coccinea, Parthenium hysterophorus and Chromolaena odorata were examined.

Leaves were extracted using different solvents such as methanol, ethanol, ethyl acetate and chloroform. Among treatments, maximum in vitro inhibition was scored in methanol extracts of C. odorata which offered inhibition zone of 10, 9, 12 and 12 mm against E. coli, S. aureus, X. vesicatoria and R. solanaccearum, respectively, followed by chloroform extract of the same plant leaf with inhibition zone of 8, 4, 4 and 4 mm, respectively. A significant inhibition of E. coli was found in aqueous and in all tested solvent extracts of A. indica. In case of S. aureus, maximum inhibition of 8 mm was obtained in aqueous extracts of A. indica and 6 mm from methanol

extract of L. inermis. The minimum inhibitory concentration (MIC) value for the clinical is confirmed.

The flowers ixora coccinea, chrysanthemum and crossandra in the application of the growth hormones in which the flower crops are grown and the observation is noted.

Rahul Kumar, Ashima Khurana, Arun K. Sharma (2014)*entitled as*"**ROLE OF PLANT HORMONES AND THEIR INTERPLAY IN DEVELOPMENT AND RIPENING OF FLESHY FRUITS"** said plant hormones have been extensively studied for their roles in the regulation of various aspects of plant development. However, in the last decade important new insights have been made into their action during development and ripening, in both dry and fleshy fruits. Emerging evidence suggests that relative functions of plant hormones are not restricted to a particular stage, and a complex network of more than one plant hormone is involved in controlling various aspects of fruit development.

Though some areas are extensively covered, considerable gaps in our knowledge and understanding still exist in the control of hormonal networks and crosstalk between different hormones during fruit expansion, maturation, and various other aspects of ripening. Here, we evaluate the new knowledge on their relative roles during tomato fruit development with a view to understand their mechanism of action in fleshy fruits. For a better understanding, pertinent evidences available on hormonal crosstalk during fruit development in other species are also discussed. We envisage that such detailed knowledge will help design new strategies for effective manipulation of fruit ripening. Fruiting bodies have evolved to facilitate seed maturation and their subsequent dispersal. A diverse range of fruit types from dry to fleshy forms exists across plant species.

Evolutionary studies predict that species that produce dry fruit are the ancestors of species that produce fleshy fruit, and this is the reason for the prevalence of common developmental mechanisms between the two types (Knapp, 2002). In *Arabidopsis*, the model plant with dry fruits, a high-level regulatory network of transcription factors controlling fruit development has been identified.

Similarly, studies on tomato, a model for fleshy fruits, have provided new insights into the networks responsible for the control of ripening (Tomato Genome Consortium, 2012).

Together, strong similarities between dry and fleshy as well as within different fleshy fruits in the molecular circuits governing development and maturation indicate that regulatory networks are conserved across a wide spectrum of angiosperm fruit (Seymour *et al.*, 2013). Though information on interplay between hormones at several levels of these steps remains scarce, nonetheless with the advent of "omics" tools, significant progress has been achieved in characterization of hormone responses (Osorio *et al.*, 2011; Rohrmann *et al.*, 2011). These efforts have led to identification of distinct as well as overlapping patterns in the expression of genes associated with hormone action across plant species.

From this we are using gibberllic acid as plant hormone is applied in flower crops growing under different mediums to estimate the growth difference.

CJ Goh (1979) *entitled as* **"HORMONAL REGULATION OF FLOWERING IN A SYMPODIAL ORCHID HYBRID *DENDROBIUM LOUISAE"*** said the growth habit, axillary bud differentiation and flowering behaviour in a sympodial orchid hybrid, DendrobiumLouisae cv. 'Dark' were studied. Flowering occurred only after termination of vegetative growth in the pseudobulb. Intermediate shoots with both vegetative and reproductive growth were produced when plants were placed in the shade. Decapitation did not stimulate floral initiation. In mature pseudobulbs, Cytokinin (benzyladenine) stimulated flowering. Gibberellic acid enhanced the cytokinin effect but was itself not effective. It is suggested that flowering in this orchid hybrid is regulated by growth substances, both qualitatively and quantitatively.

In this they are using cytokinin and gibberllic acid is applied in orchid hybrid to regulate the hormonal regulation. From this we are taken gibberllic acid is applied in three flower crops to stimulate the flowering and bud initiation.

CHAPTER 3

METHODOLOGY

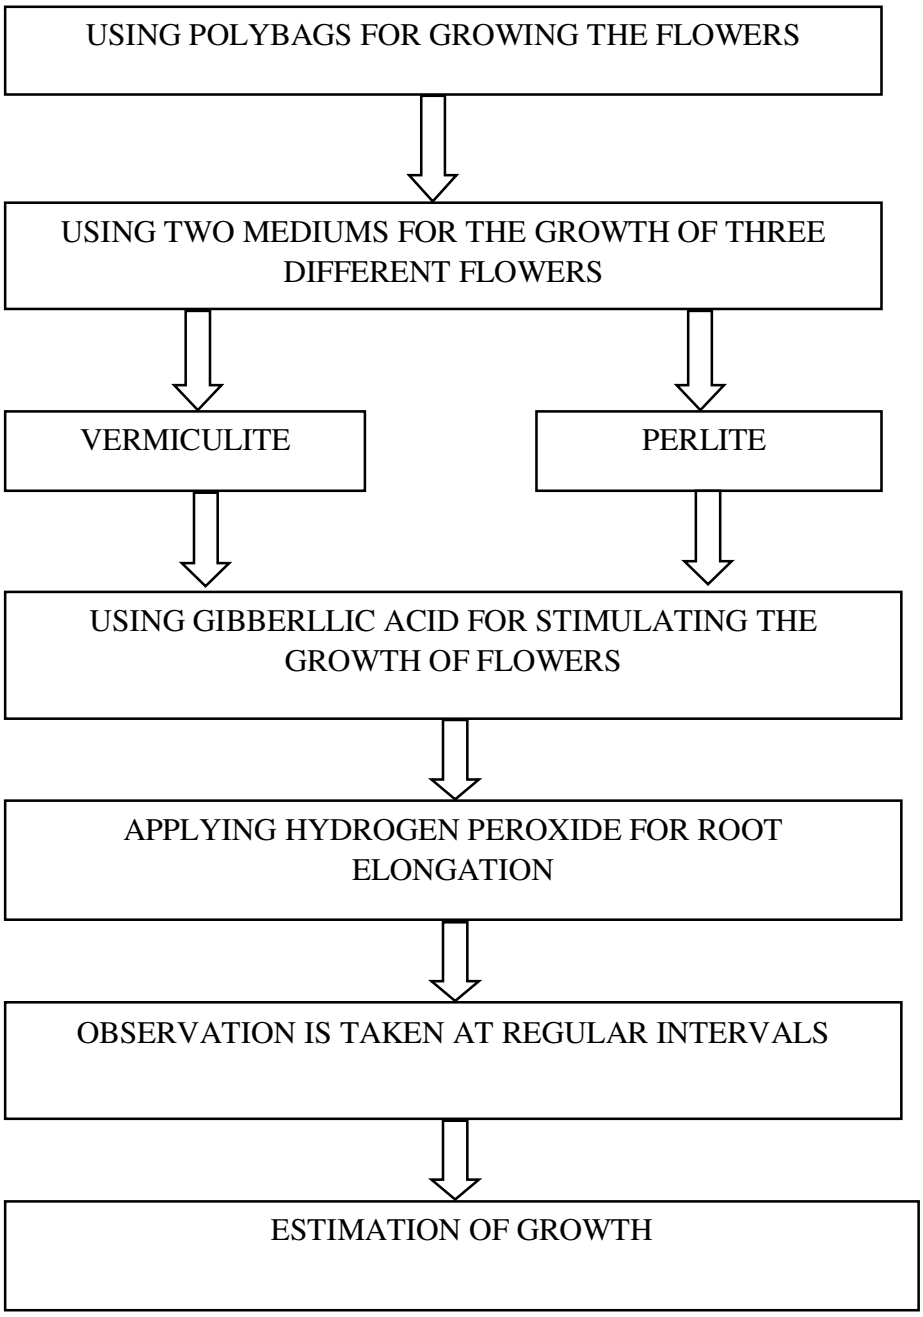

FIGURE 3.1 Methodology of flowchart

3.1 Using polybags for growing the flowers

In this we are using polybags for growing three different flowers such as Crossandra, Chrysanthemum and Ixora coccinea under polyhouse cultivation. The polyhouse enhances the growth of the plants under favorable conditions.

3.2 Using two different mediums for the growth of flowers

We are using two mediums such as vermiculite and perlite applied in three different flowers to estimate the growth difference. Each flower crops is treated with two different mediums to calculate the growth compared with normal growth of flower crops.

3.3 Vermiculite

It is an aluminium-iron-magnesium silicate that resembles mica in appearance. When vermiculite is soaked in water for some hours it enlarges its volumes up to 3 to 4 times in its original volume. It is filled in polybags and growing the seedlings by adding some water. It improves soil aeration, retaining moisture, nutrients to feed roots, cuttings, seeds for faster and maximum growth. Vermiculite acts more like sponge and holding much more water.

3.4 Perlite

It is an amorphous volcanic glass that has relatively high water content greatly expanding when heated. Perlite can absorb 2 to 3 times its weight in water. It provides proper aeration and excellent water retention properties. We were applied perlite in separate polybags and growing flower seedlings to estimate the growth of the plants.

3.5 Using gibberllic acid for stimulating the growth of flowers

We are using growth hormone gibberllic acid in three flower crops to stimulate the flower initiation, shoot elongation. We are taking amount of gibberllic acid and add few drops of rubbing alcohol in order to dilute the gibberllic acid powder. Then just add water to get the right concentration. Finally the prepared gibberllic acid is sprayed on plants.

3.6 Apply hydrogen peroxide for root elongation:

Mix 3% of hydrogen peroxide into a gallon of water. Then spray the solution for every 3 to 5 days. This helps to maintain healthy soil, allow roots to breath and elongate root elongation.

3.7 Observation is taken at regular intervals:

We are taking observation at 15 days interval to calculate the growth differences among the flower crops compared with normal growth of the flower.

3.8 Estimate the growth:

Finally we are estimating the plant height, no of leaves, stem height and leaf length are analyzed and compared with normal growth of the flowers.

CHAPTER 4

MATERIALS REQUIRED

4.1. GIBBERLLIN

A single low concentration of GA 3 application did not interfere with the phenotypic characteristics of the chrysanthemum cultivar Faroe Gibberellins commonly known as gibberellic acids first came to the attention of western scientists in 1950's, they had been discovered much earlier in Japan. Rice farmers of Japan had long known of a fungal disease called foolish seedling or *bakanae* disease in Japanese that causes rice plants to grow taller and eliminated seed production. Plant pathologists found that these symptoms in rice plant were induced by a chemical secreted by a pathogenic fungus, *Gibberellafujikuroi*. Culturing this fungus in the laboratory and analyzing the culture filtrate enabled Japanese scientists in the 1930s to obtain impure crystal of two fungal "compounds" possessing plant growth promoting activity. One of these, because it was isolated from the fungus *Gibberella*, was named gibberellin A. In 1950s scientists of Tokyo University separated and characterized 3 different gibberellins from gibberellin A sample, and named them gibberellin A_1, gibberellin A_2 and gibberellin A_3. The numbering system for gibberellins used in the past 50 y builds on this initial nomenclature of gibberellins A_1(GA_1), GA_2, and GA_3.In the same year, 2 research groups, one at Imperial Chemical Industries in Britain and other at the US Department of Agriculture (USDA) in Illinois, elucidated the chemical structure of the compound that they had purified from *Gibberella* culture filtration and named gibberellic acid.

This compound was later shown to be identical to the gibberellin isolated by the Japanese scientist. For this GA_3 is also referred to as gibberellic acid. GA_3 is the principal component in *Gibberella* culture. The GA_3 is the most frequently produced GA in commercial industrial scale fermentations of *Gibberella* for agronomic, horticultural and other scientific uses.

Identification of a GA from a plant extract was first made in 1958 with the discovery of GA_1 from immature seeds of bean (*Phaseoluscocineus*). As more and more GAs from *Gibberella* and different plant sources were characterized, a scheme was adopted in 1968 to

number them (GA_1–GA_4), in chronological order of their discovery. Gibberellic acid (GA), a plant hormone stimulating plant growth and development, is a tetracyclic di-terpenoid compound. GAs stimulate seed germination, trigger transitions from meristem to shoot growth, juvenile to adult leaf stage, vegetative to flowering, determines sex expression and grain development along with an interaction of different environmental factors viz., light, temperature and water. The major site of bioactive GA is stamens that influence male flower production and pedicel growth. However, this opens up the question of how female flowers regulate growth and development, since regulatory mechanisms/organs other than those in male flowers are mandatory. Although GAsare thought to act occasionally like paracrine signals do, it is still a mystery to understand the GA biosynthesis and its movement. It has not yet confirmed the appropriate site of bioactive GA in plants or which tissues targeted by bioactive GAs to initiate their action. Presently, it is a great challenge for scientific community to understand the appropriate mechanism of GA movement in plant's growth, floral development, sex expression, grain development and seed germination.

FIGURE 4.1 Gibberllic acid

4.1.1 Properties of gibberellin

- It promotes growth and elongation of cells.
- It stimulates rapid stem and root growth.
- It increases the seed germination rate.

- It breaks the dormancy.
- It increases the flower budding level.

4.1.2 Treatment of gibberellin

The gibberellin is used as a growth regulator for the shoot development of three different applications in flower crops by which the application is done for the plant by mixing with water in a one third ratio for its development of growth of the plant.

4.2 HYDROGEN PEROXIDE

Hydrogen peroxide is a very pale blue, clear liquid, slightly more viscous than water. Hydrogen peroxide is the simplest peroxide (a compound with an oxygen–oxygen single bond). It is used as an oxidizer, bleaching agent, and antiseptic. Hydrogen peroxide is the simplest peroxide (a chemical with an oxygen–oxygen single bond). It is a colorless liquid at room temperature. Small amounts of gaseous hydrogen peroxide occur naturally in the air, but it is unstable and decomposes readily to oxygen and water with release of heat. Hydrogen peroxide is used as a chemical intermediate, as a bleaching agent in the paper and textile and pulp industry, and in water treatment operations. Hydrogen peroxide is a strong oxidizing agent characterized by a chemical structure that possesses unpaired electrons. This makes it highly reactive and gives it the ability to damage cellular macromolecules, including proteins, lipids, and nucleic acids.

Hydrogen peroxide is corrosive to the skin and the eyes and its vapor is irritating to the respiratory tract. Ingestion of hydrogen peroxide may produce oxygen bubbles, or oxygen embolism, in the blood, resulting in hemodynamic compromise, including cardiovascular collapse. There is inadequate evidence in humans for carcinogenicity, genotoxicity and reproductive toxicity of hydrogen peroxide.

Hydrogen peroxide can be used for any of the following in the garden: pest control treating root rot pre-treating seeds foliar spray to kill fungus infection preventive on damaged trees While it has also been used as a general "fertilizer" either added in during watering or sprayed onto the foliage, hydrogen peroxide is not fertilizer, but it can help boost plant growth. Hydrogen peroxide helps encourage healthy root growth because of the extra oxygen molecule. Oxygen can

help plant roots absorb nutrients from the soil. Therefore, this extra bit of oxygen better enables the roots to absorb more nutrients, which means faster, healthier, and more vigorous growth.

Hydrogen peroxide can help discourage unwanted bacteria/fungi that may be lurking in the garden. To give plants an added boost of oxygen or for pest control using the 3% solution, add 1 teaspoon per cup of water in a spray bottle and mist the plant. This amount is also suitable for pre-treating seeds to control fungal infections. For plants with root rot or fungal infections, use 1 tablespoon per cup of water. The solution can be made up and stored for future use, but be sure to store it in a cool, dark place as exposure to light diminishes the potency. Mix one part hydrogen peroxide to ten parts of water. That is one cup per four square feet of garden. Mix the solution in a watering can or into a large sprayer. Water at the base of the plants and avoid wetting the foliage. Be very careful when using this percentage of peroxide. It can bleach and/or burn the skin. Spray the veggie garden after every rainfall or as needed.

It is not only this is an environmentally friendly alternative to pesticides, but it has the added benefit of being anti-fungal and gives plants a healthy boost of oxygen too. Hydrogen peroxide, well known as an ingredient in disinfectant products, is now also approved for controlling microbial pests on crops growing indoors and outdoors, and on certain crops after harvest. This active ingredient prevents and controls bacteria and fungi that cause serious plant diseases.

FIGURE 4.2 hydrogen peroxide

4.2.1Properties of hydrogen peroxide

- It helps to encourage healthy root growth because of the extra oxygen molecules`
- It acts as an antimicrobial agent.
- It controls the pest and root rot disease.
- It is acidic in nature.
- It has a viscosity higher than water.

4.2.2 Treatment of hydrogen peroxide

The application of hydrogen peroxide is done in the floral growth for the availability of extra oxygen molecules in the plant growth. It is applied on the basis of 5 ml of dosage for the plant growth.

4.3 VERMICULITE

It is a group of platy minerals, hydrous silicates of aluminum, magnesium, and iron that expand markedly on being heated: used in the expanded state for heat insulation and as a plant growth medium. Vermiculite, hydrous phyllosilicate minerala undergoes significant expansion when heated.

Exfoliation occurs when the mineral is heated sufficiently, and commercial furnaces can routinely produce this effect. Vermiculite formed by the weathering or hydrothermal alteration of biotite or phlogopite. Large commercial vermiculite mines currently exist in Russia, South Africa, China, and Brazil. It has been used in various industries for over 80 years. It is used in industrial markets, agriculture, construction etc. Vermiculite is the mineralogical name which has given to hydrated laminar magnesium-aluminum-iron silicate which resembles mica in appearance. Vermiculite is a naturally occurring mineral that is mined and processed into puffy, lightweight granule which is mixed with soil to improve aeration and drainage.

They provide highest quality agricultural vermiculite specially meant for agriculture purposes and it has the excellent properties to be essential component for seedling, planting, germination and cutting. It improves aeration. It loosens the soil so that the roots can easily reach down and grow through the soil .It exchange drainage and small, round white particles of exfoliated vermiculite do not absorb water, each little bead creates a tiny pocket among the granules of soil. Water can easily flow through the soil and the roots. It is great for clay soils and helps to improve drainage in any area. It act as a Permanent Soil Conditioner. Unlike compost (decayed organic matter), eventually breaks down into the soil, vermiculite does not break down. Compost does add vital nutrients, but if you need to improve drainage permanently then vermiculite is a great solution.

Vermiculite is a pH neutral, which is around 7.0 or so, but because of some compounds found within it, it can slightly raise pH, a plus for acidic soils. Exfoliated vermiculite naturally reacts with soil compounds and makes the availability of other nutrients such as calcium, potassium and magnesium. Most commercial potting soil comes premixed with vermiculite, so there needs a purpose to add it.

FIGURE 4.3 Vermiculite

4.3.1 Properties of vermiculite:

- It has a high cation exchange capacity.
- It contains aluminium, iron, magnesium and silicates.
- It has high water holding and air holding capacity.

- It absorbs excess nutrients.
- It is a non abrasive and non irritant.

4.3.2 Treatment of vermiculite:

The vermiculite is used as a medium by which the growth of the flower crops is observed. Their heat insulation capacity will make the medium to expand and the availability will be more in its content.

4.4 PERLITE:

Perlite is a glassy volcanic rock with a rhyolitic composition and 2–5 per cent of combined water. The main known world's perlite reserves (about 70 per cent) are located along the Aegean coast in Turkey. The commercial product is produced by heating the ground, sieved material to 760–1100°C. The combined water in the perlite is converted to gas at high temperature in the oven and subsequently the volume expands 4–20 times its original volume, resulting in a lightweight high porosity material. Perlite is frequently used in potting soil mixtures and as a standalone growing medium. It is produced in various grades, the most common being 0–2 and 1.5–3.0 mm in diameter. The various grades differ in their physical characteristics.

Physical Characteristics – Expanded perlite is very light with a particle and BD of 0.9 and 0.1 g cm^{-3}, respectively. It is very porous, has a strong capillary action and can hold 3–4 times its weight in water. Burés et al. (1997a) reported that water retained at 10 kPa is much higher for the coarse fraction (0.5–1.0 mm diameter) than for the fine fraction (0.25–0.50 mm diameter) of expanded perlite. This difference in water-holding capacity between the coarse and fine fractions indicates that most of the water is held by the coarse particles in internal pores. However, it is not explained by the volume of internal porosity. The slope of the reduction in water content as the water tension increases is moderate relative to sand and stone wool. The available and non-available water in commercial perlite of 0–4 mm diameter was 13.6 and 36.5 per cent of its volume, respectively. The water retention curve of perlite shows moderate hysteresis. The saturation of perlite was very rapid, independent of its initial moisture. The saturated hydraulic conductivity depends on particle diameter.

For commercial perlite of 0–4 mm diameter, having 50 per cent of the particles smaller than 0.5 mm, saturated hydraulic conductivity was 0.3 cm min^{-1} . A reduction of 2 orders of magnitude in the hydraulic conductivity was obtained as the water suction increased from 0 to 30 cm water. This change is moderate in comparison to sand.

Chemical Characteristics – Perlite is neutral with a pH of 7.0–7.5, but it has no buffering capacity and contains no mineral nutrient. When the pH is low there is a risk of toxic Al release into the solution. In horticultural applications, perlite is used throughout the world as a component of soil-less growing mixes where it provides aeration and optimum moisture retention for superior plant growth. For rooting cuttings, 100% perlite is used. Studies up have shown that outstanding yields are achieved with perlite hydroponic systems. Other benefits of horticultural perlite are its neutral pH and the fact that it is sterile and weed-free. In addition, its light weight makes it ideal for use in container growing. Other horticultural applications for perlite are as a carrier for fertilizer, herbicides and pesticides and for pelletizing seed. Horticultural perlite is as useful to the home gardener as it is to the commercial grower. It is used with equal success in greenhouse growing, landscaping applications and in the home in house plants.

FIGURE 4.4 Perlite

4.4.1Properties of perlite:

- It makes soil ventilated and improves its drainage.
- It increases infiltration and decreases evaporation.
- It makes moisture and nutrients readily available to plants.
- Salt acts as a soil improver.

4.4.2 Treatment of perlite:

The perlite is the one used as a medium for the growth of the different flower plants in which its increase the growth of them by its capacity of withholding the moisture for a longer period of time.

FIGURE 4.5 Different treatments

CHAPTER 5

PACKAGE OF PRACTICES

5.1 PACKAGE OF PRACTICE OF CHRYSANTHEMUM

FAMILY:

Asteraceae

VARIETY:

CO2

COLOUR:

Purple

TEMPERATURE:

16 to 250 Celsius

RELATIVE HUMIDITY:

70 to 85%

CO2:

600 – 900 ppm

PHOTOPERIOD:

Long day conditions with 13 hours light and 11 hours darkness during vegetative stage

SOIL:

We are using sandy loam soil as growing medium in polybags

GROWING MEDIA:

We are using vermiculite and perlite as growing medium in 6 pots. Vermiculite is soaking in water for some hours it enlarges 3 to 4 times its original volume and placed in to separate three polybags. Perlite is placed in 3 polybags separately to increasing its original volume 2 to 3 times by the addition of water.

PROPAGATION:

Terminal cuttings

PLANTING:

20 days old saplings are transplanted in to separate polybags.

IRRIGATION:

Apply 1.2 liters of water per week.

GROWTH REGULATORS:

We are taking amount of gibberllic acid and add few drops of rubbing alcohol in order to dilute the gibberllic acid powder. Then just add water to get the right concentration. Finally the prepared gibberllic acid is sprayed on plants in 3 pots in perlite medium.Mix 3% of hydrogen peroxide into a gallon of water. Then spray the solution for every 3 to 5 days in 3 polybags in vermiculite medium. This helps to maintain healthy soil, allow roots to breath and elongate root elongation

PINCHING:

First pinching is done in 3 weeks after planting.

OBSERVATION PERIOD:

We are transplanting 20 days old saplings of cut chrysanthemum in separate polybags and the flower initiate from the 45 days after planting.

DISEASES:

Fusarium wilt. It is caused by fusarium oxysporum due to water stress and poor drainage. Stems show a reddish brown discolourisation of vascular systems. The infected plants show chlorosis and necrosis starting from lower leaves. The apical leaves show curving. It is controlled by spraying Bavistin at 0.05% and carbendazium at 0.1% is sprayed in 15 days interval.

BIOMETRIC OBSERVATION:

PLANT HEIGHT:

By using gibberllic acid in perlite medium the plant height is 22.2 cm is increased compared with using hydrogen peroxide the plant height is 18.3 cm in perlite and also grown greater than normal growth of about 11 cm.

By using hydrogen peroxide in vermiculite medium the plant height is 21.2 cm is increased compared with using gibberllic acid the plant height is 16.3 cm in vermiculite and also grown greater than normal growth of about 11 cm.

NO OF LEAVES:

By using gibberllic acid in perlite medium the no of leaves 28 is increased compared with using hydrogen peroxide the no of leaves is 25 in perlite and also the leaves are higher than the normal growth of leaves is 12.

By using hydrogen peroxide in vermiculite medium the no of leaves 20 is increased compared with using gibberllic acid the no of leaves 15 in vermiculite and also the leaves are higher than the normal growth of leaves is 12.

LEAF LENGTH:

By using gibberllic acid in perlite medium the leaf length is 5.5 cm is increased compared with using hydrogen peroxide the leaf length is 4.2 cm in perlite and also grown greater than normal growth of leaf length is about 2 cm.

By using hydrogen peroxide in vermiculite medium the leaf length is 6.1 cm is increased compared with using gibberllic acid the leaf length is 4.7 cm in vermiculite and also grown greater than normal growth of leaf length is about 2 cm.

STEM HEIGHT

By using gibberllic acid in perlite medium the stem height is 11 cm is increased compared with using hydrogen peroxide the stem height is 8.3 cm in perlite and also grown greater than normal growth of about 6 cm.

By using hydrogen peroxide in vermiculite medium the stem height is 13.5 cm is increased compared with using gibberllic acid the stem height is 10 cm in vermiculite and also grown greater than normal growth of about 6 cm.

HARVEST:

The correct stage of harvesting is done in 50 days after planting.

5.2 PACKAGE OF PRACTICE OF CROSSANDRA

FAMILY:

Acanthaceae

VARIETIES:

Arka ambara

COLOUR:

Orange

TEMPERATURE:

30 to 35 Celsius

RELATIVE HUMIDITY:

50 to 65%

PH:

6 to 7.5

SOIL:

We are using sandy loam soil as growing medium in polybags.

GROWING MEDIA:

We are using vermiculite and perlite as growing medium in 6 pots. Vermiculite is soaking in water for some hours it enlarges 3 to 4 times its original volume and placed in to separate three polybags. Perlite is placed in 3 polybags separately to increasing its original volume 2 to 3 times by the addition of water.

PROPAGATION:

Seeds can be propagated through terminal cuttings.

PLANTING:

Seedlings are transplanted at 4 to 6 leaves stage that is 8 to 10 days old saplings are transplanted in to the polybags.

IRRIGATION:

Irrigation is done at weekly intervals.

GROWTH REGULATORS:

We are taking amount of gibberllic acid and add few drops of rubbing alcohol in order to dilute the gibberllic acid powder. Then just add water to get the right concentration.

Finally the prepared gibberllic acid is sprayed on plants in 3 pots in perlite medium. Mix 3% of hydrogen peroxide into a gallon of water. Then spray the solution for every 3 to 5 days in 3 polybags in vermiculite medium. This helps to maintain healthy soil, allow roots to breath and elongate root elongation

PINCHING:

First pinching is done in 3 weeks after planting.

OBSERVATION PERIOD:

We are transplanting 10 days old saplings of crossandra in separate polybags and the flower initiate from the 55 days after planting.

DISEASES:

Wilt. It is caused by fusarium solani. Leaves of infected plants become pale and drop. Margin of the leaves show pinkish brown discolourisation. It is controlled by spraying Bavistin at 0.05% and carbendazium at 0.1% is sprayed in 15 days interval. The affected plants should be pulled out and destroyed to reduce the diseases.

BIOMETRIC OBSERVATION:

PLANT HEIGHT:

By using gibberllic acid in perlite medium the plant height is 18.1 cm is decreased compared with using hydrogen peroxide the plant height is 24.7 cm in perlite and also grown greater than normal growth of about 10.6 cm.

By using hydrogen peroxide in vermiculite medium the plant height is 17.5 cm is decreased compared with using gibberllic acid the plant height is 26.3 cm in vermiculite and also grown greater than normal growth of about 10.6 cm.

NO OF LEAVES:

By using gibberllic acid in perlite medium the number of leaves 17 is decreased compared with using hydrogen peroxide the no of leaves is 21 in perlite and also the leaves are higher than the normal growth of leaves is 9.

By using hydrogen peroxide in vermiculite medium the no of leaves 24 is decreased compared with using gibberllic acid the no of leaves 30 in vermiculite and also the leaves are higher than the normal growth of leaves is 9.

LEAF LENGTH:

By using gibberllic acid in perlite medium the leaf length is 3.8 cm is decreased compared with using hydrogen peroxide the leaf length is 4.6 cm in perlite and also grown greater than normal growth of leaf length is about 2.4 cm.

By using hydrogen peroxide in vermiculite medium the leaf length is 3.8 cm is decreased compared with using gibberllic acid the leaf length is 5.3 cm in vermiculite and also grown greater than normal growth of leaf length is about 2.4 cm.

STEM HEIGHT:

By using gibberllic acid in perlite medium the stem height is 11.2 cm is decreased compared with using hydrogen peroxide the stem height is 13.3 cm in perlite and also grown greater than normal growth of about 8.6 cm.

By using hydrogen peroxide in vermiculite medium the stem height is 11.8 cm is decreased. Compared with using gibberllic acid the stem height is 15.6 cm in vermiculite and also grown greater than normal growth of about 8.6 cm.

HARVEST:

The correct stage of harvesting is done in 80 days after planting.

5.3 PACKAGE OF PRACTICES OF IXORA COCCINEA

FAMILY:

Rubiaceae

ANOTHER NAME:

Jungle geranium, flame of woods, jungle flame

VARIETY:

Coccinea

PHOTOPERIOD:

It must have at least four hours a day of direct sunlight

COLOUR:

Red

TEMPERATURE:

15 Celsius

RELATIVE HUMIDITY:

60 to 70%

PH:

6 to 7.5

SOIL:

We are using sandy loam soil as growing medium in polybags

GROWING MEDIA:

We are using vermiculite and perlite as growing medium in 6 pots. vermiculite is soaking in water for some hours it enlarges 3 to 4 times its original volume and placed in to separate three polybags. Perlite is placed in 3 polybags separately to increasing its original volume 2 to 3 times by the addition of water.

PROPAGATION:

Seeds can be propagated through stem cuttings. Trim each cutting immediately below a leaf, remove that leaf and dip the cue end in hormone rooting powder.

PLANTING:

Seedlings are transplanted at 4 to 6 leaves stage that is 8 to 10 days old saplings are transplanted in to the polybags.

PRUNING:

Pruning can be control its shape and size

IRRIGATION:

Irrigation is done at weekly intervals

GROWTH REGULATORS:

We are taking amount of gibberllic acid and add few drops of rubbing alcohol in order to dilute the gibberllic acid powder. Then just add water to get the right concentration. Finally the prepared gibberllic acid is sprayed on plants in 3 pots in perlite medium. Mix 3% of hydrogen peroxide into a gallon of water. Then spray the solution for every 3 to 5 days in 3 polybags in vermiculite medium. This helps to maintain healthy soil, allow roots to breath and elongate root elongation.

PINCHING:

First pinching is done in 2 weeks after planting.

OBSERVATION PERIODS:

We are transplanting days old saplings of crossandra in separate polybags and the flower initiate from the 55 days after planting.

DISEASES:

Leaf spot. It is a result of various fungal pathogens that cause discoloured spots, raised areas or brownish yellow patches on the leaves of infected plants. Preventing this fungal disease by avoiding over watering and removing plant matter that has fallen to the ground.

BIOMETRIC OBSERVATION:

PLANT HEIGHT:

By using gibberllic acid in perlite medium the plant height is 30.5 cm is increased compared with using hydrogen peroxide the plant height is 22.3 cm in perlite and also grown greater than normal growth of about 18.4 cm.

By using hydrogen peroxide in vermiculite medium the plant height is 28.6 cm is increased compared with using gibberllic acid the plant height is 20.7 cm in vermiculite and also grown greater than normal growth of about 18.4 cm.

NO OF LEAVES:

By using gibberllic acid in perlite medium the no of leaves 45 is increased compared with using hydrogen peroxide the no of leaves is 29 in perlite and also the leaves are higher than the normal growth of leaves is 18.

By using hydrogen peroxide in vermiculite medium the no of leaves 22 is increased compared with using gibberllic acid the no of leaves 16 in vermiculite and also the leaves are higher than the normal growth of leaves is 18.

LEAF LENGTH:

By using gibberllic acid in perlite medium the leaf length is 18.7 cm is increased compared with using hydrogen peroxide the leaf length is 13.6 cm in perlite and also grown greater than normal growth of leaf length is about 10 cm.

By using hydrogen peroxide in vermiculite medium the leaf length is 19.2 cm is increased compared with using gibberllic acid the leaf length is 14.5 cm in vermiculite and also grown greater than normal growth of leaf length is about 10 cm.

STEM HEIGHT:

By using gibberllic acid in perlite medium the stem height is 23.5 cm is increased compared with using hydrogen peroxide the stem height is 19.2 cm in perlite and also grown greater than normal growth of about 11.3 cm.

By using hydrogen peroxide in vermiculite medium the stem height is 21.2 cm is increased compared with using gibberllic acid the stem height is 17.6 cm in vermiculite and also grown greater than normal growth of about 11.3 cm.

HARVEST:

The correct stage of harvesting is done in 75 days after planting.

planting

CHAPTER 6

RESULT AND DISCUSSION

From this project we have observed the growth of flower crops in gibberllic acid is increased in Chrysanthemum and Ixora coccinea in perlite medium. It increased the leaf length, no of leaves, stem length and plant height.

The effect of hydrogen peroxide is increased in crossandra in vermiculite medium. It increased the root elongation, stem and plant height.

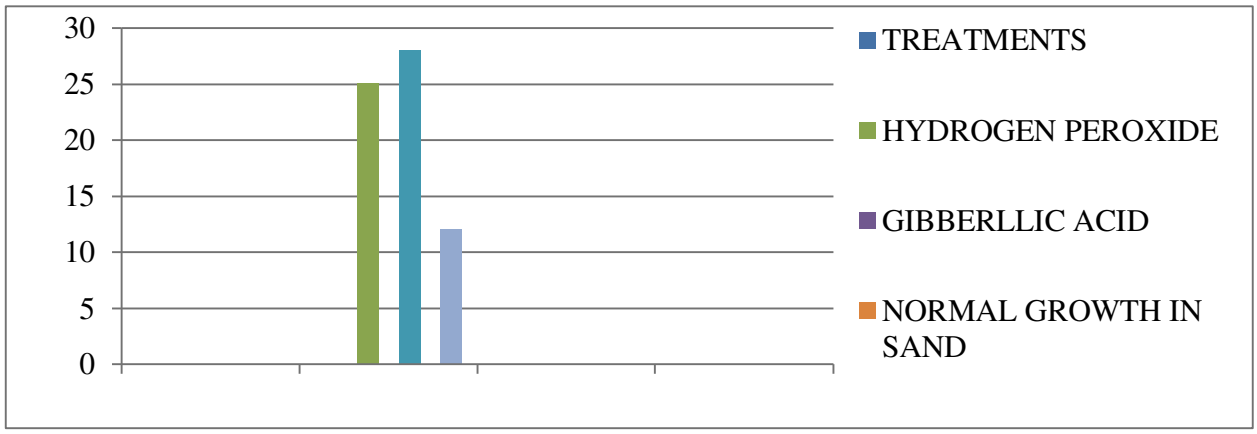
6.1 TABLES

6.1.1 CHRYSANTHEMUM

Table.6.1.observation period for 30 days using perlite as medium in chrysanthemum

TREATMENTS	PLANT HEIGHT (CM)	NO OF LEAVES	LEAF LENGTH (CM)	STEM HEIGHT (CM)
HYDROGEN PEROXIDE	18.3	25	4.2 cm	8.3
GIBBERLLIC ACID	22.2	28	5.5 cm	11
NORMAL GROWTH IN SAND	11	12	2 cm	6

Graph.1



The observation of the plant is taken for the 30 days in which the plant height, number of leaves, leaf length and stem height are increased in gibberllic acid compared with the hydrogen peroxide and normal growth.

The table shows that the major variation of the crop chrysanthemum is increased by using perlite as the medium in the first 30 days of growth and the effect of applying gibberllic acid in the crop than hydrogen peroxide and in the normal growth.

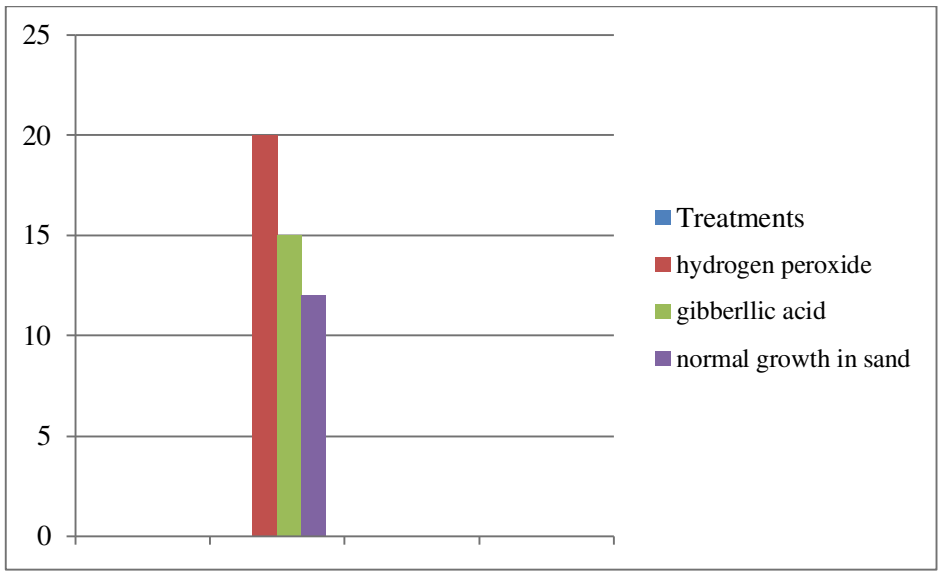
The graph represents the growth of plant by applying gibberllic acid in perlite medium is increased when compared with the normal growth and hydrogen peroxide in which it increases the growth in the flower crop chrysanthemum .

6.1.2 CHRYSANTHEMUM

Table 6 .2 observation period for 30 days using vermiculite as medium in chrysanthemum

TREATMENTS	PLANT HEIGHT (CM)	NO OF LEAVES	LEAF LENGTH (CM)	STEM HEIGHT (CM)
HYDROGEN PEROXIDE	21.2	20	6.1	13.5
GIBBERLLIC ACID	16.3	15	4.7	10
NORMAL GROWTH IN SAND	11	12	2	6

Graph.2



The observation of the plant is taken for the 30 days in which the plant height, number of leaves, leaf length and stem height are increased in hydrogen peroxide compared with the gibberllic acid and normal growth.

The table shows that the major variation of the crop chrysanthemum is increased by using vermiculite as the medium in the first 30 days of growth and the effect of applying gibberllic acid in the crop than hydrogen peroxide and in the normal growth.

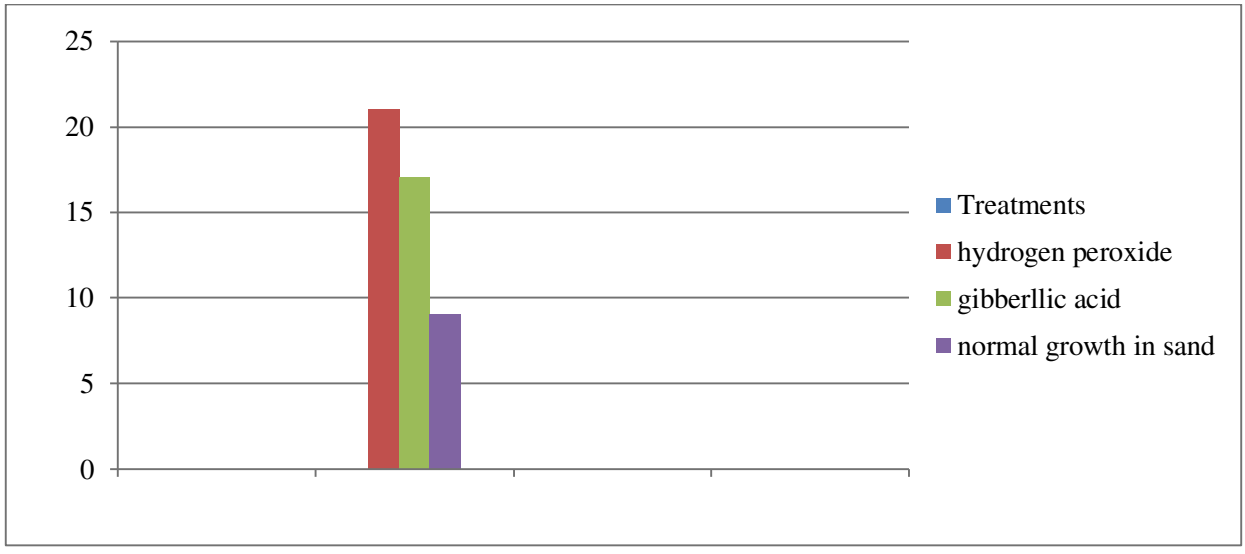
The graph represents the growth of plant by applying hydrogen peroxide in vermiculite medium is increased when compared with the normal growth and hydrogen peroxide in which it increases the growth in the flower crop chrysanthemum .

6.1.3 CROSSANDRA

Tabl6e. 3 observation period for 30 days using perlite as medium in crossandra

TREATMENTS	PLANT HEIGHT (CM)	NO OF LEAVES	LEAF LENGTH (CM)	STEM HEIGHT (CM)
HYDROGEN PEROXIDE	24.7	21	4.6	13.3
GIBBERLLIC ACID	18.1	17	3.8	11.2
NORMAL GROWTH IN SAND	10.6	9	2.4 cm	8.6

Graph.3



The observation of the plant is taken for the 30 days in which the plant height, number of leaves, leaf length and stem height are increased in hydrogen peroxide compared with the gibberllic acid and normal growth.

The table shows that the major variation of the crop crossandra is increased by using perlite as the medium in the first 30 days of growth and the effect of applying hrdrogen peroxide in the crop than gibberllic acid and in the normal growth.

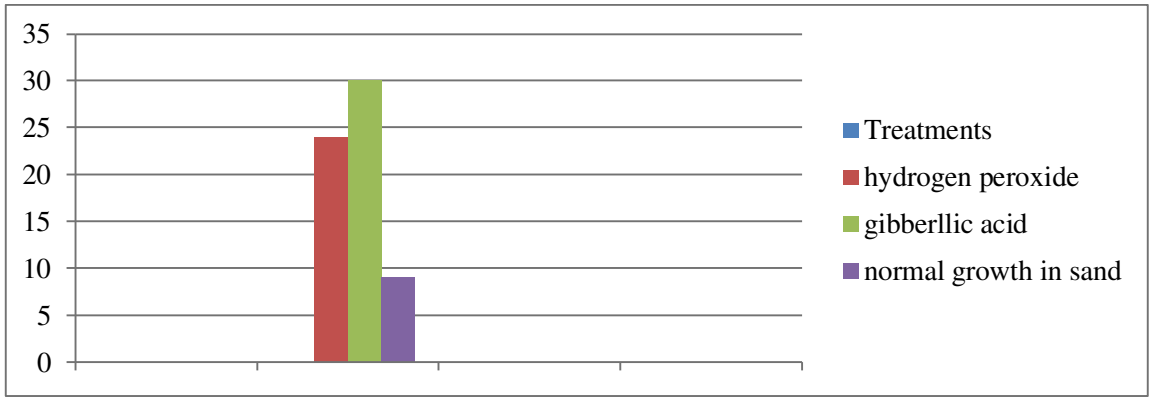
The graph represents the growth of plant by applying hydrogen peroxide in perlite medium is increased when compared with the normal growth and gibberllic acid in which it increases the growth in the flower crop crossandra.

6.1.4 CROSSANDRA

Table6 .4 observation period for 30 days using vermiculite as medium in crossandra

TREATMENTS	PLANT HEIGHT (CM)	NO OF LEAVES (CM)	LEAF LENGTH (CM)	STEM HEIGHT (CM)
HYDROGEN PEROXIDE	17.5	24	5.3	11.8
GIBBERLLIC ACID	26.3	30	3.8	15.6
NORMAL GROWTH IN SAND	10.6	9	2.4	8.6

Graph.4



The observation of the plant is taken for the 30 days in which the plant height, number of leaves, leaf length and stem height are increased in gibberllic acid compared with the hydrogen peroxide and normal growth.

The table shows that the major variation of the crop crossandra is increased by using vermiculite as the medium in the first 30 days of growth and the effect of applying gibberllic acid in the crop than hydrogen peroxide and in the normal growth.

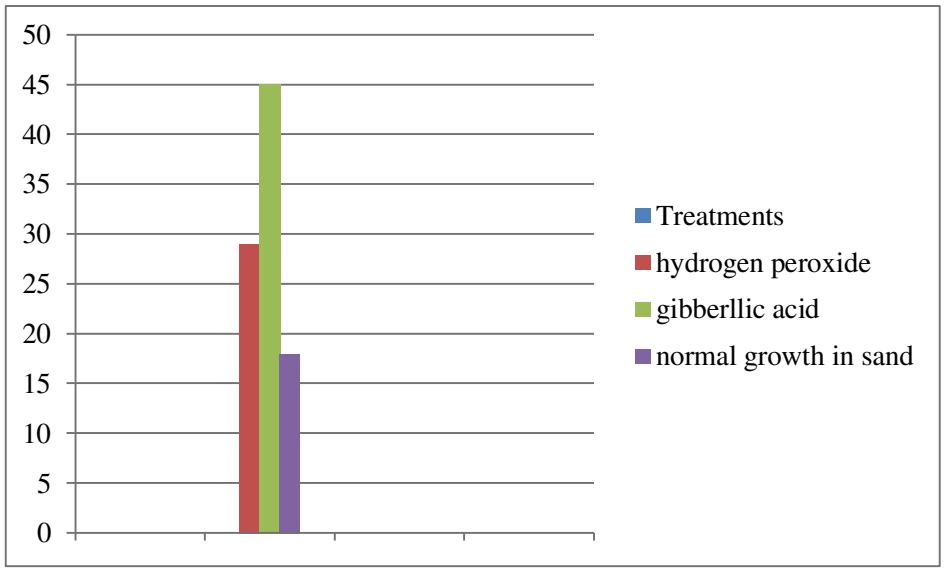
The graph represents the growth of plant by applying gibberllic acid in vermiculite medium is increased when compared with the normal growth and hydrogen peroxide in which it increases the growth in the flower crop crossandra.

6.1.5 IXORA COCCINEA

Table6 .5 observation period for 30 days using perlite as medium in ixora coccinea

TREATMENTS	PLANT HEIGHT (CM)	NO OF LEAVES	LEAF LENGTH (CM)	STEM HEIGHT (CM)
HYDROGEN PEROXIDE	22.3	29	13.6	19.2
GIBBERLLIC ACID	30.5	45	18.7	23.5
NORMAL GROWTH IN SAND	18.4	18	10	11.3

Graph.5



The observation of the plant is taken for the 30 days in which the plant height, number of leaves, leaf length and stem height are increased in gibberllic acid compared with the hydrogen peroxide and normal growth.

The table shows that the major variation of the crop Ixora coccinea is increased by using perlite as the medium in the first 30 days of growth and the effect of applying gibberllic acid in the crop than hydrogen peroxide and in the normal growth.

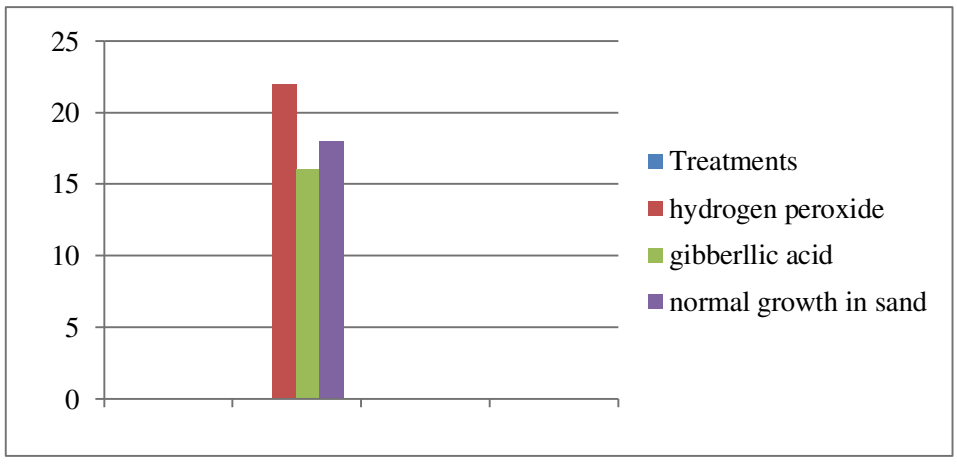
The graph represents the growth of plant by applying gibberllic acid in perlite medium is increased when compared with the normal growth and hydrogen peroxide in which it increases the growth in the flower crop Ixora coccinea .

6.1.6 IXORA COCCINEA

Table6 .6 observation period for 30 days using vermiculite as medium in ixora coccinea

TREATMENTS	PLANT HEIGHT (CM)	NO OF LEAVES	LEAF LENGTH (CM)	STEM HEIGHT (CM)
HYDROGEN PEROXIDE	28.6	22	19.2	21.2
GIBBERLLIC ACID	20.7	16	14	17.6
NORMAL GROWTH IN SAND	18.4	18	10	11.3

Graph.6



The table shows that the major variation of the crop Ixora coccinea is increased by using vermiculite as the medium in the first 30 days of growth and the effect of applying hydrogen peroxide in the crop than gibberllic acid and in the normal growth.

The graph represents the growth of plant by applying hydrogen peroxide in vermiculite medium is increased when compared with the normal growth and gibberlic acid in which it increases the growth in the flower crop Ixora coccinea .

RESULT AND DISCUSSION

From this project we have observed the growth of flower crops in gibberllic acid is increased in Chrysanthemum and Ixora coccinea in perlite medium. It increased the leaf length, no of leaves, stem length and plant height.

The effect of hydrogen peroxide is increased in crossandra in vermiculite medium. It increased the root elongation, stem and plant height.

CONCLUSION

The graph represents the growth of plant by applying gibberllic acid in perlite medium is increased when compared with the normal growth and hydrogen peroxide in which it increases the growth in the flower crop chrysanthemum

The graph represents the growth of plant by applying hydrogen peroxide in vermiculite medium is increased when compared with the normal growth and hydrogen peroxide in which it increases the growth in the flower crop chrysanthemum .

The graph represents the growth of plant by applying gibberllic acid in perlite medium is increased when compared with the normal growth and hydrogen peroxide in which it increases the growth in the flower crop Ixora coccinea .

The graph represents the growth of plant by applying gibberllic acid in vermiculite medium is increased when compared with the normal growth and hydrogen peroxide in which it increases the growth in the flower crop crossandra

OCTOBER- 2019

ABSTRACT

This project presents the plan, analysis and design of a shopping mall structure of an underground car parking storey and G+2 stories and investigate its performance under various lateral loading conditions. The main goal is to assess current Indian Standard design practice and to analyze using STAAD Pro and to find a detailing strategy which will ensure a sufficient level of safety for various levels of loading demands.

In this project we will design and analyze the building which utilize this limited area and satisfying each and every needs of the people. It will also designed in such a way that it would be economical. The civil engineers have to think of construction of high rise structures, instead of the traditional type of reinforced concrete structure enclosed by thick walls of bricks or any other construction materials.

CHAPTER 1

INTRODUCTION

Structural design is "An Art of understanding the behavior of structural elements subjected to different types of loads". "It is the art of calculation of internal forces like design moments, shear forces, axial load and twisting moments in structural elements". A typical four storied building has been taken for design. Usually multi-storied buildings are constructed in the form of reinforced concrete framed structures which is also said as "Rigid Frame".

1.1 Planning and Construction:

Structural planning and construction starts with group collaboration between client, Architect, Structural Engineer, Consultant and contracting firm.

1.2 Structural Planning:

Structural planning of the frame is done after getting the architectural drawing.

- Positioning and orientation of columns
- Positioning of beams
- Spanning of slabs
- Layout of stairs
- Selecting proper type of footing

1.3 Action of Forces and Computation of Loads:

The design engineer should have clear concept of the action forces acting on the structure. The basic structural actions which a structural engineer should know are as follows.

1.3.1 Axial Force:

Axial force occurs in the member like columns, arches, cables and trusses due to force passing through the centroidal axis. Membrane action which occurs in the structures like shells and plates along the surface only.

1.3.2 Bending Action:

Forces which are parallel or transverse to the member axis cause bending

action. It occurs essentially in case of 2D structures like slabs and beam.

1.3.3 Shear Action:

Shear action is induced by in-plane parallel forces only.

1.3.4 Twisting Action:

Torsional moment induced in the out of plane of forces. E.g., beam holding cantilever slabs, beams curved in plan.

1.3.5 Combined Action:

It is the combination of one or more of the above action.

1.4 Analysis of Structures:

Elastic analysis: Used in working stress method.

Limit analysis: Used in limit state design for RCC structures.

1.5 Member Design:

It involves the design of slab, beam, column and footing sequentially.

1.6 Detailing, Drawing and Preparation of Schedule:

Detailing and drawing preparation should do after ensuring adequate strength and satisfactory behavior of structure. Detailed drawing and schedule should prepare for all reinforcement details such as footing, column, beam, staircase and slabs.

CHAPTER 2

ANALYSIS OF SECTION USING STAAD Pro

2.1 About STAAD Pro:

STAAD Pro (Structural Analysis and Design Program) is one of the most popular structural engineering software products for 3D model generation analysis and multi- material design. It has an intuitive, user-friendly GUI, visualization tools, powerful analysis and design facilities and seamless integration to several other modeling and design software products. The software is fully compatible with all Windows operating systems but is optimized for Windows XP.

For static or dynamic analysis of bridges, containment structures, embedded structures (tunnels and culverts), pipe racks, steel, concrete aluminum or timber buildings, transmission towers, stadiums or any other simple or complex structure, STAAD Pro has been the choice of design professionals around the world for their analysis needs.

2.2 STAAD Pro Overview:

2.2.1 Types of structures:

- **Space:** Three dimensional framed structures with loads applied in any plane.
- **Plane:** Two dimensional structures framed in the X-Y plane with loads in same plane.
- **Floor:** Two or three dimensional structures having no horizontal (Global X or Z) movement of structures (FX, FY & MY are restrained at every joint).
- **Truss:** Any structures consists of truss members only, we can have only axial member forces and no bending in members.

2.2.2 Overall Procedure in Working with STAAD Pro Model Generation:

There are two methods for building a model and assigning the structure data using STAAD Pro.

- Using the command file.
- Using the graphical model generation mode or graphical user interface (GUI).

2.3 Performing Analysis and Design:

The Modeling Mode of the STAAD Environment is used to prepare the structural input data. After the input is prepared, we may choose to analysis engine depending upon the nature of the analysis required.

2.4 Post-Processing:

The Post Processing mode of STAAD offers facilities for on screen visualization and verification of the analysis and design results.

The pages in this mode allow us to view displacements, forces, stresses, etc both graphically and numerically.

2.5 Summary

- Creating a structural model. This consists of generating the structural geometry, specifying member properties, materials constants, load, analysis and design specifications, etc.
- Visualization and verification of the model geometry.
- Running the STAAD analysis engine to perform analysis and design.

2.6 Verification of results:

- Graphically and numerically.
- Report generation and printing.
- Inter-operability. In other words, using STAAD Pro in conjunction with other programs, such as STAAD etc, STAAD Foundation.

CHAPTER 3

DESIGN OF SHOPPING MALL

3.1 Design of Two Way Slab:

3.1.1 Data:

Span = 6 m × 4m

Live load = 4 kN/m^2

Finish = 1 kN/m^2

F_{ck} = 25 N/m^2

F_y = 415 N/m^2

3.1.2 Type of Slab:

L_y / L_x = 6 / 4

= 1.5 < 2

Hence two way slab

3.1.3 Calculation of Effective Depth:

Overall depth, D = Effective span / 25

= 4000 / 25

= 160 mm

Assuming a clear cover of 30 mm, Effective depth,

d = 160 - 30 mm

= 130 mm

3.1.4 Calculation of Effective Span:

c / c of support:

= 4000 + 230 / 2 + 230 / 2

= 4230 mm

Clear span + depth:

= 4000 + 130

= 4130 Mm

3.1.5 Load Calculation:

Self weight of slab = 25 x 0.16 x 1

	=	4 kN/m^2
Floor finish	=	1 kN/m^2
Live load	=	4 kN/m^2
Total service load, w	=	9 kN/m^2
Ultimate load, W_u	=	1.5 x 9
	=	13.5 kN/m^2

3.1.5 Ultimate Design Moments and Shear Force Refer IS 456:2000 Table 6:

L_Y / l_x	=	1.5
α_x	=	0.104
α_y	=	0.046
M_{ux}	=	$\alpha_x W u L_x^2$
	=	0.104 x 13.5 x 4^2
	=	22.464 kNM
M_{ux}	=	$\alpha_y W u L_x^2$
	=	0.46 x 13.5 x 4^2
	=	9.93 kNM
V_{ux}	=	$W_U L_X / 2$
	=	13.5 x 4 / 2
	=	27 kN

3.1.6 Check for Depth:

M_{max}	=	$0.138 f_{ck} b d^2$
d^2	=	22.46 x 10^6 / 0.138 x 25 x 1000
d	=	80.685 < 130 mm

Hence the effective depth selected is sufficient to resist the design ultimate moment.

3.1.7 In X-Direction:

22.46x10^6	=	0.87 x A_{st} x 415 x 130 (1- A_{st} x 415 / 1000 x 130 x 25)
A_{st}	=	571.96 mm^2

Adopt 10 mm diameter bars at 300 mm

A_{st}	=	78.53 mm
S	=	(78.53 / 571.96) x1000
	=	137.29 mm = 140 mm

3d = 3 x130

= 390 mm

Provide 140 mm @10 mm dia

A_{st} = 78.53 / 140 x 1000

= 560.92 mm^2

3.1.8 In Y-Direction:

$9.936x10^6$ = 0.87 x A_{st} x 415 x 130 (1-A_{st} x 415/1000 x 130 x 25)

A_{st} = 217.7 mm^2

Adopt 10 mm diameter bars at 300 mm

A_{st} = 78.53mm

S = (78.53 / 217.7) x 1000

= 360.72 mm

= 360 mm

3d = 3 x130

= 390 mm

Provide 140 mm@10mm dia

A_{st} = 78.53 / 360 x1000

= 218.13 mm^2

3.1.9 Check For Shear Stress:

Considering the short span unit width of slab

τv = Vu / b.d

= 27 x 10^3 / 1000 x 130

= 0.207 N / mm^2

P_t = A_{st} x 100 / b d

= 100 x 217.7 / 1000 x 130

= 0.16%

Refer table 19 – IS 456 and read out

$k\tau c$ = 0.39 x 0.27

= 0.105 Nmm^2

$K\tau c$ = τv

Hence the shear stresses are within safe permissible limits.

3.1.10 Check for Deflection Control

Considering unit width of slab in short span direction L_x

(L/d) basic = 30

P_t = 0.16

Refer IS 456 fig;4,5,6

K_t = 1.4

K_c = 1

K_f = 1

$(L/d)_{max}$ = 4000 / 160

= 25

Hence deflection control is satisfied

3.1.11 Torsional Reinforcement:

A_{st}, for torsional = 0.75 x A_{st} provided

= 0.75 x 511.96

= 384 mm^2

Length over which torsion steel is provided

= (1/5) x short span

= (1/5) x 4000

= 800 mm

Provide 8mm dia bar @ 130mm for a 1span of 800mm at all 4 corners

3.2 Design of Beam:

3.2.1 Cross Sectional Dimension:

Effective span = 6.00m

Span/depth = 24

Depth(d) = 250 mm

Overall depth = 250 + 50

D = 300 mm

3.2.2 Ultimate Moment and Shear Force:

Max Bending Moment = 700 kN-m

Max Shear Force = 200 kN

3.2.3 Limiting moment:

M_u limit = $0.138 \times fck \times b \times d^2$

= $0.138 \times 25 \times 300 \times 250^2$

= 85.39 kN-m

$M_u > M_u$ limit so the section is over reinforced

3.2.4 Main Reinforcement:

To find A_{sc}

Mu - Mu limit = $f_{sc}A_{sc}$ (d – d")

F_s = $0.0035 \times (Xumax - d") / Xumax \times Es$

$\frac{Xumax}{d}$ = 0.48

Xumax = 0.48×250

= 120 mm

Provide 5 no of 16 mm dia bar

f_{sc} = $(0.0035 \times (360 - 50) / 360) \times 2 \times 10^5$

= 602.74 N / mm^2

Y = 0.87 x 415

= $361N/mm^2$

Mu – Mu limit = $F_{sc}A_{sc}$ (d – d")

205.15 = $361 \times A_{sc}$ (250 - 50)

A = 629.90 mm^2

A_{sc} provide = 804.3 mm^2

To find A_{st}

A_{st} $A_{st1} + A_{st2}$

A_{st1} $(0.36 \times f_{ck} \times b \times Xumax) / (0.87 \times f_y)$

$0.36\ 25 \times 300 \times 360 / 0.87 \times f_y$

2692.74 mm^2

3.3 Design of Lintel:

3.3.1 Data:

Size of lintel = 230 x 150 mm

Using 8mm ϕ with a Nominal Cover of 20mm d= D – NC - ϕ/2

= 150 – 24

= 126 mm

Span = 4000 mm

Height of equilateral Triangle = 0.866 x L

= 0.866 x 4000

= 3.464 m

Height of wall above the lintel = 3.5 - (2.1 + 0.15)

= 1.25 m

3.464 m > 1.25 m

3.3.2 Load Calculation:

Weight of Triangular Position of Masonry

W_1 = ½ x b x h x d x Weight of masonry

= ½ x 1 x 1.25 x 0.23 x 18

= 2.58 kNm

Weight of Sunshade

Assume sunshade depth 150 mm = 1 x 0.6 x 0.15 x 25

= 2.25 kN/m

Self-weight of Lintel = 0.23 x 0.15 x 1 x 25

= 0.86 kN/m

Total UDL (W) = 5.69 kN/m

Factored UDL (Wu) = 5.69 x 1.5

= 8.53 kN/m

Maximum Bending Moment

$$M = \frac{w \times Le^2}{8}$$

$$= \frac{8.53 \times 4^2}{8}$$

$$= 17.06 \text{ kN m}$$

Area of Steel Required

Mu $= 0.87 \times f_y \times A_{st} \times d \times \left(1 - \frac{A_{st} \times f_y}{F_{ck} \times bd}\right)$

$A_{st} = 110.84 \text{ mm}^2$

A_{st} min $= 0.12\ \% \times b \times d$

$= 0.12 /100 \times 230 \times 126$

$= 34.78 \text{ mm}^2$

$= \frac{\pi}{4} \times 8^2$

$= 50.26 \text{ mm}^2$

No of bars $= \frac{A_{st}}{a_{st}}$

$= \frac{110.84}{50.26}$

$= 3$ Nos

Provide 3Nos of 8 mm ø bar Fe 415 steel bar @ bottom as main reinforcement & 2Nos of 8 mm ø bar @ top as hanger bar.

Details

Length	4000mm
Breadth	230mm
Depth	150mm

Main Reinforcement

Top	Provide 2Nos of 8mm ø bar Fe415 steel bar
Bottom	Provide 3Nos of 8mm ø bar Fe415 steel bar
Stirrups	8mm dia 2 legged stirrup 170mmc/c

3.3Design of Sunshade:

Data

Assume on conforni thickness of 150 mm width of effective depth of 130mm. Consider 1m length of sunshade.

Self-weight of sunshade = 1x 0.6 x 0.15 x 25

= 2.25 kN

Factored load (W) = 2.25 x 1.5

= 3.37 kN/m

To Find Moment

$$Mu = \frac{W \times L}{2}$$

$$= \frac{3.37 \times 10^3 \times 600}{2}$$

$$= 1.01 \times 10^6 \text{ N mm}$$

To Find Area of Steel Requirement

$$Mu = 0.87 \times f_y \times A_{st} \times d \times \left(1 - \frac{A_{st} \times f_y}{F_{ck} \times bd}\right)$$

$$0.87 \times 415 \times A_{st} \times 130 \times \left(1 - \frac{A_{st} \times 415}{25 \times 1000 \times 130}\right)$$

A_{st} = 21.72 mm^2

A_{st} min = 0.12 % x b x d

= 0.12 /100 x 1000 x 150

= 180 mm^2

$$= \frac{\pi}{4} \times 6^2$$

= 28.27 mm^2

No of bars = $\frac{A_{st}}{a_{st}}$

$$= \frac{180}{28.27}$$

= 6 Nos

Provide 6Nos of 6mm ø main bar @ 157mm C/C.

Details

Length = 600 mm

Thickness of slab = 150 mm

Main reinforcement 6 nos of 6 mm Ø @ 157 mm c/c.

Distributor 6 nos of 6 mm Ø @ 180 mm c/c

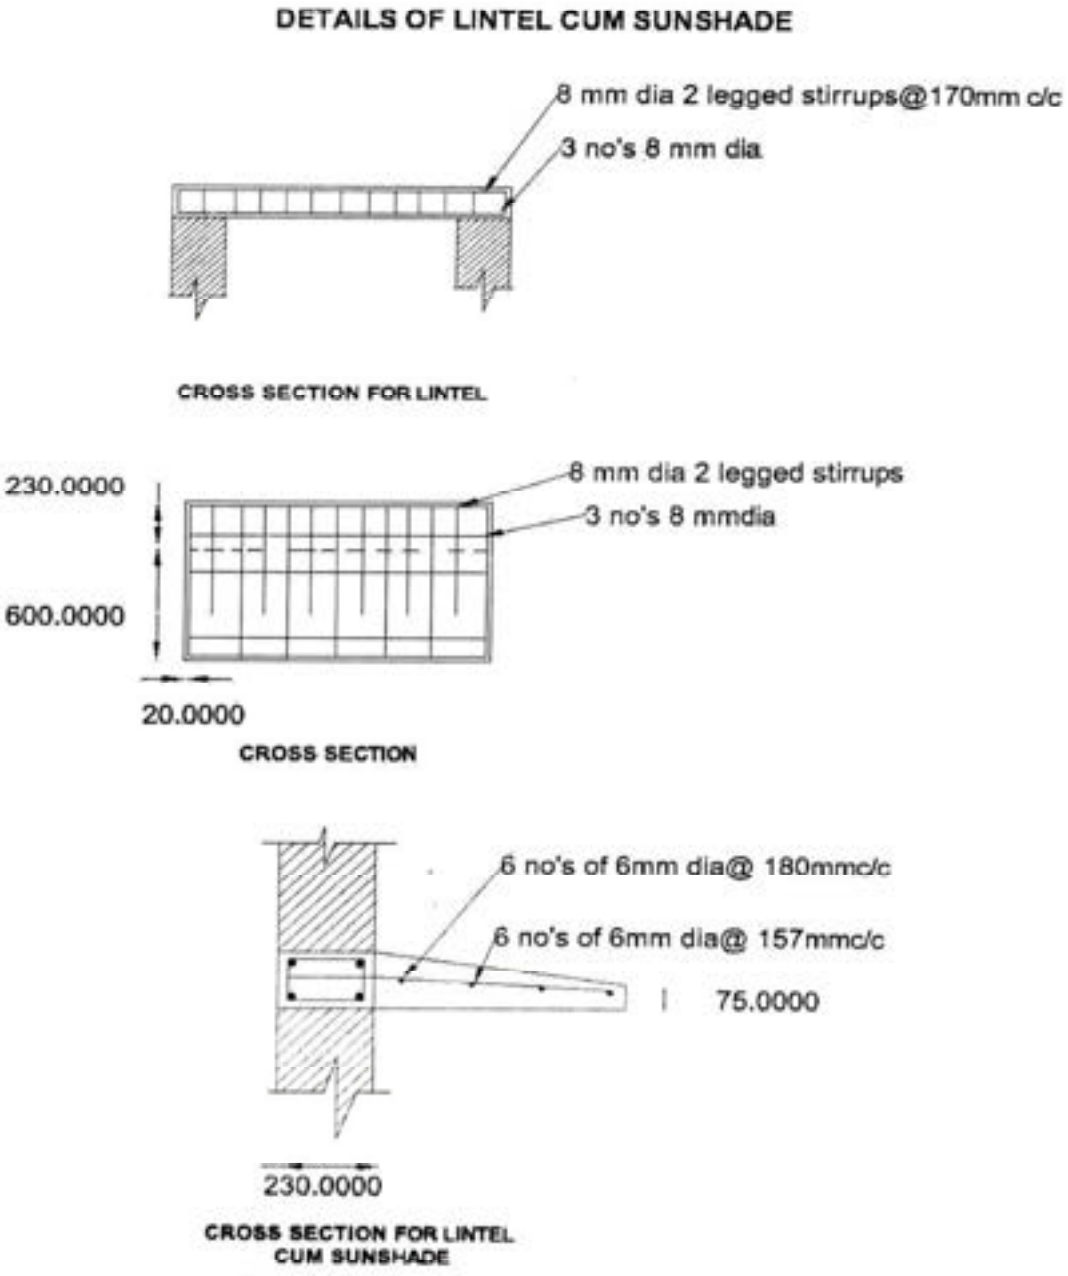

Figure 3.1 Reinforcement details of lintel cum sunshade

3.4 Design of Dog Legged Staircase:

Given Data

Rise	= 180 mm
Tread	= 300 mm
L	= 3400 mm
B	= 2440 mm
F_{ck}	= 25 N/mm^2
F_y	= 415 N/mm^2
No of steps	= 20 No's

To Find Dimensions

$\frac{span}{depth}$ = 20

$\frac{3400}{depth}$ = 20

d = 170 mm

Assume 10 mm dia & NC 15 mm

Over all depth (D) = d + N

= 170+15

= 185 mm

= 4.62 kN/m

To Find Load Calculation:

Dead loads of slab on slope Wd = 0.185 x 1 x 25

= 4.62 kN/m

3.5 Design of Septic Tank:

Number of Users = 1000

Rate of water supply = 135 lit/head/day

The quantity of water supplied = Per capita rate X Population

= 1000 X 135

= 135,000 lit/day

Assuming that 80% of water supplied becomes sewage, we have the quantity of sewage produced.

= 135000 x 0.8

= 108000 lit/day

Assuming the detention time to be 24 hours, we have

The quantity of sewage produced during the detention period (i.e., the capacity of the tank)

= (108000 x 24)/24

= 108000 liters

Now assuming the rate of deposited sludge as 30 liters/capita/year; and also assuming the period of cleaning as 1 year, we have

The Volume of Sludge deposited

= 30 x 1000 x 1

= 30000 liters Total required capacity of the tank

= Capacity for sewage + Capacity for sludge

= 108000 + 30000

= 138000 liters

= 138cu-m

Assuming 3 m as the depth of the tank, we have

The surface area of the tank = $138/3\ m^2$

= $46\ m^2$

If the ratio of the length to width is kept as 31, we have

3B x B	= 46
B^2	= 46 / 3
	= 15.33
say	= 4m
Provide Width	= 4m
Provide length of the tank	= 12 m
Area of cross-section provided	= 12 x 4
	= $48\ m^2$ (same as required)

Thus, the dimensions of the septic tank will be 12 m x 4 m x (3 + 0.3) m overall depth, [0.3 m used as free-board]

Hence, Use a tank of size is (12 x 4 x 3.3) m

Design of Dispersion Trench:

Flow of sewage per day = 135

Extra flow taken for future expansion = 12.15 m^3

Assume the percolating capacity of Filter media of the pit as = 1.25 $m^3/m^2/day$

Volume of pit required = 147.15 / 1.25

= 117.72 m^3

Assume the depth of pit 3.5 m below the invert level the inlet pipe.

Area required = 117.72 / 3.5

= 33.63m^2

D = $\sqrt{(4x7.08/3.14)}$

D = 6.5 m

CONCLUSION

A three storey R.C.C framed structure is designed as a shopping mall this design adopted in limit state method of design M_{20} grade of concrete and Fe_{415} grade of steel are used. All structural elements are designed as balanced section. Analysis of the frame is carried out by substitute frame method.

The Planning Analysis and Design of Apartment building are done carefully based upon the knowledge obtained from the theoretical studies and guide lines from IS 456:2000 and SP-16.The Planning of the building is made as per the guideline of NBC.

The design of slabs, beams, column pile foundation and staircase were done manually and the analysis is done by using STAAD Pro software. All the drawings presented in this project report were drafted using AUTOCAD 2012 software. The beams have been designed by taking both bending moment and shear force from the analysis result into consideration.

The shopping mall which we designed is good in economical as well as commercial.

ABSTRACT

This Project work deals with the Planning Analysis and Design of Residential building. It is a RC framed structure consists of two storey. This plan includes all the requirements of residential building.

This structure is analyzed and designed by manual design. The code refers for this project are NBC, IS 456-2000.

The concrete mix used for slabs, beams, columns, column footing is of M_{25}. The steel strength for all members are high yield strength deformed bars of grade Fe_{415}

For the design of the slab, beams, columns, and footings LIMIT STATE METHOD of design has been adopted.

CHAPTER 1

INTRODUCTION

The residential building means like house or home to the usage of living peoples in safely and create a healthy family.The study of ventilation in residential buildings is aimed at understanding the role that air leakage, infiltration, mechanical ventilation, natural ventilation and building use have on providing acceptable indoor air quality so that energy and related costs can be minimized without negatively impacting indoor air quality.

Risks to human health and safety caused by inappropriate changes to ventilation and air tightness can be a major barrier to achieving high performance buildings and must be considered. This research area focuses primarily on residential and other small buildings where the interaction of the envelope is important and energy costs are dominated by space conditioning energy rather than air transport energy. A building used for dwelling purposes is known as residential buildings.

Double bed room houses are more advantages such houses do not have limited budget.All bed rooms can be on Ground floor or can be designed on different floors.Sizes of various bed rooms depend on the plot area and personal likings of the users.

CHAPTER 2

SYNOPSIS

Planning analysis and designing of Residential building with double bed rooms is our project which is to propose at namakkal Dt.

SCOPE OF THE PROJECT:

The Residential building consists of a,

- Living and dining
- Master bed room 1
- Bed room 2
- Store room
- kitchen
- Bath & toilet

BRIEF METHODOLOGY:

Drafting method for design the plan is by Auto cad . The framed type of construction is used for the construction and the designing of structure is carried out by limit state method with the IS 456: 2000 code book. The analysis is carried out by using limit state method.

The center line method of estimation is carried out for calculating the quantity and the rates are adapted from the current government rates .The availability of men and materials is in local itself.

EXPECTED OUTCOME:

The plan and structural elements such as slab, beam, column and footings are designed using limit state method. This project helps us in exploring knowledge about planning, analyzing and designing a Residential Building with triple bed rooms.

CHAPTER 3

LIST OF NOTATIONS

The following letter symbols have the meaning indicated against each which is used in this project book.

B	=	Breadth of the beam or slab.
D	=	Overall depth of beam or slab.
d	=	Effective depth of beam or slab.
F_{ck}	=	Characteristic strength of the concrete.
F_y	=	Characteristic strength of the steel.
K	=	Constant of co-efficient of factor.
L_{ex}	=	Effective length of shorter side of slab.
L_{ey}	=	Effective length of longer side of slab.
SV	=	Spacing of stirrups.
V	=	Shear force.
Vu	=	Design Shear force.
W	=	total load.
Wu	=	Factored load.
σ_{cbc}	=	Compressive bending stress in concrete.
σ_{max}	=	Maximum shear stress in concrete with shear.
B_V	=	Basic value.
Mf	=	Modification factor.
F_U	=	Factored live load.
Le	=	Effective length.
A_{st}	=	Area of tension steel
A_{sc}	=	Area of compression steel
A_{CC}	=	Area of concrete
A_{SV}	=	Total cross sectional area of stripes
F.F.L	=	Floor finish load
D.L	=	Dead load

C.C	=	Cement concrete
C.M	=	Cement mortar
R.C.C	=	Reinforced cement concrete
P	=	Axial load
L	=	clear span
M.R	=	Moment of resistance
C/C	=	Center to center distance
S.F	=	Shear force
M	=	Modular ratio
MBM	=	Maximum bending moment
C.C	=	Clear cover
W.S	=	Width of support
N.C	=	Nominal cover
τ_v	=	Actual shear stress
$\tau_{c\,max}$	=	Maximum shear stress
τ_c	=	Permissible shear stress
Q_U	=	Moment of resistance co-efficient
Ag	=	Gross sectional area of column
Ast_{req}	=	Area of tension steel required
Ast_{prov}	=	Area of tension steel provided
#	=	Diameter of bars
S_C	=	Stress in concrete
S_s	=	Stress in steel

STAAD SYMBOLS:

M_z	=	Bending moment
F_y	=	Shear force
F_x	=	Axial shear force
M_{30}	=	Grade of concrete
V_Y	=	Shear strength

L_D	=	Length of beam
P_{UZ}	=	Strength of column
IR	=	Interaction ratio

CHAPTER 4

SPECIFICATION

I. FOUNDATION:-

Earth work excavation for foundation for all column footings will be excavated and will be in cement concrete 1:1:2 mix, 800 mm wide and 800 mm thick laid at 1250 mm below ground level. The masonry footings will be in brickwork in cement mortar 1:6. The footing size is 800 x 800 mm. The foundation concrete for framed structure ,all main wall and footing of cement concrete of 1:1:2 mix, will be provided .

II. BASEMENT:-

The basement will be in 1st class brick work in cement mortar 1:5, and 300 mm thick above ground level for all walls. The basement will be filled with clean sand to a depth of 200 mm. A damp proof course in cement mortar 1:3, 50 thick will be provided for all walls at basement level.

III. SAND FILLING IN BASEMENT:-

The basement filled up with clean sand to a depth of 300mm and it should be compacted with water as per standard specifications.

IV. DAMP PROOF COURSE:-

A Damp proof course using cement mortar 1:3 of 50mm thick will be Provide for all main walls at basement level.

V.FLOORING CONCRETE:-

The flooring concrete of 1:1:2 mix with suitable thick will be provided should be finished above the sand filling and it by mosaic tiles.

VI. SUPER STRUCTURE:-

All the walls will be in I class brick work in cement mortar 1:5, using first class bricks, and 230 mm thick. The height of all walls will be 3000 mm above floor level. All the walls including basement will be plastered smooth with cement mortar 1:4 externally and 1:6 internally for 12.5 thick. Parapet walls 230 mm thick and 1000 mm high will be provided all around. The beams and

columns sizes as 300mm x440 mm and 300x300mm will be provided all around.

VII. ROOFING:-

The roofing will be of R.C.C 1:1:2 mix, 150 mm thick flat slabs over all the rooms. A weathering course in brick jelly lime concrete plastered with combination mortar 1:1:2 mix, 75 mm thick will be provided over the slab.

VIII. LINTEL:-

All internal wall openings will be provided with R.C.C lintel 1:1:2mix, 120 mm thick and all external walls openings will be provided with lintel cum sunshade 1:1:2 mix, 120 mm thick and sunshade will be 600 mm wide.

IX. SUNSHADE:-

600mm wide projections with 150mm thick at fixed end and 50mm thick at free end will be provided for all external opening using R.C.C 1:1:2 mix.

X.PLASTERING FOR SUPER STRUCTURE:-

All walls will be plastered smooth surface with cement Mortar 1:3, 12 mm thick.

XI.SOUND PROOFING FOR CEILING & WALL:-

In ceiling of all rooms and walls are soundproofed with latest type soundproofing material.

XII. WEATHERING COURSE:-

A Weathering course using brick jelly concrete will be provided average 75 mm thick over the slab and finished with two course of hydraulic pressed Mangalore flat tiles using cement mortar 1:5 mixed with 10% of crude oil.

XIII. WHITE WASHING:-

One primer coat and two coats of colour wash to be done for all plastered wall surface.

XVI. STEPS:-

The step will be in brick work in cement mortar 1:5,

Rise =150 mm,

Tread =300 mm.

CHAPTER 5

STRUCTURAL DESIGN

5.1 DESIGN OF TWOWAY SLAB FOR BED ROOM 2

AVAILABLE DATA:

f_{ck} = 25 N/mm^2

f_y = 415 N/mm^2

Room size = 4.3 x 4.8 m

Support = 230 mm

Thickness of slab = 150 mm

TYPE OF SLAB:

l_y / l_x = 11/10

= 1.1 < 2

Hence designed as two way slab

DESIGN CONSTANT :

Basic value = 32 (continuous slab)

Q_u = 3.45

OVER ALL DEPTH:

Assume Clear cover 15 mm

Diameter of main bar = 10 mm

For Shorter span,

D = 150 mm

d_{eff} = 150 - 15 -10/2 = 130 mm

For Longer span,

d = 150 -10 = 140 mm

D = 140 + 15 + 10/2 = 160 mm

EFFECTIVE SPAN:

For shorter span,

i) Center to center of supports = 4300 + 230 = 4530 mm

ii) Clear span + effective depth = 4300 + 130 = 4430 mm

For longer span,

i) Center to center of supports = 4800 + 230 = 5030 mm

ii) Clear span + effective depth = 4800 + 130 = 4930 mm

LOAD CALCULATION:

Consider 1m width of slab

Live load = 2 KN/m^2

Self weight of slab = 1 x b x D x unit weight

= 1 x 1 x 0.15 x 25

= 3.75 KN/m^2

Weight of floor finish = 1x 1 x 0.05 x 20 = 1.0 KN/m^2

Total load = 6.75 KN/m

Design load = 6.75 x 1.5 = 10.125 KN/M

FACTORED MOMENT :

l_y / l_x = 4.93 / 4.43 = 1.11

-veαx	+veαx	-veαy	+veαy
0.053	0.040	0.047	0.035

For shorter span,

$-veM_x = \alpha x\ wlx^2 = 0.053 \times 10.125 \times (4.43)^2$

$= 10.53 \times 10^6$ N.mm

$+veM_x = \alpha x\ wlx^2 = 0.040 \times 10.125 \times (4.43)^2$

$= 7.94 \times 10^6$ N.mm

For longer span,

$-veM_y = \alpha y\ wlx^2 = 0.047 \times 10.125 \times (4.43)^2$

$= 9.33 \times 10^6$ N.mm

$+veM_y = \alpha y\ wlx^2 = 0.035 \times 10.125 \times (4.43)^2$

$= 6.95 \times 10^6$ N.mm

Maximum moment $= 10.53 \times 10^6$ N.mm

DEPTH REQUIRED :

$M_u = M_u \max$

$M_u = Q_u x b \times d^2$

$d = \sqrt{M_u / Q_u b}$

$= \sqrt{10.53 \times 10^6 / 3.45 \times 1000}$

$= 55.24$ (say) 60 mm D = 80 mm

$d_{req} = d_{pro}$ 60 mm < 130 mm

TYPE OF SECTION :

$M_{u\ limit} = Q_u \times b \times d^2$

$= 3.45 \times 1000 \times 130^2$

$= 58.30 \times 10^6$ N.mm^2

$M_u < M_{u\ limit}$

DISTRIBUTOR REINFORCEMENT

A_{st} min = 0.12 / 100 x B x D

$= 0.12 / 100 \times 1000 \times 150$

$= 180$ mm^2

SPACING:

Assume 10 mm dia of bars

1) $S = a_{st} / A_{st}$min x b = 78.54 / 180 x 1000

= 440 mm

2) 5d = 5 x 130 = 650 mm

3) 450 mm

Provide 10 mm dia bars @ spacing 440 mm c/c

MAIN REINFORCEMENT:

For shorter span (max mom in shorter span)

$M_x = 0.87\ f_y A_{st}\ d\ (1 - f_y A_{st} / f_{ck} bd)$

$10.53 \times 10^6 = 0.87 \times 415 \times A_{st} \times 130$

$(1 - 415 \times A_{st} / 25 \times 1000 \times 130)$

$5.99\ A_{st}^2 - 46.93 \times 10^3 A_{st} + 10.53 \times 10^6 = 0$

$A_{st}\ min = 231.20\ mm^2$

SPACING:

Assume 10 mm dia bars

1) $S = a_{st}/A_{st} \times b = 78.54 / 231.20 \times 1000$

   $= 340$ mm

2) $3d = 3 \times 130 = 390$ mm

3) 300 mm c/c

Provide 10 mm dia bars @ spacing 300 mm c/c distance.

For longer span:

$M_y = 0.87\ fy A_{st}\ d\ (1 - fy A_{st} / bd\ fck)$

$9.33 \times 10^6 = 0.87 \times 415 \times A_{st} \times 130\ (1 - 415 \times A_{st} / 25 \times 1000 \times 130)$

$5.99\ A_{st}^2 - 46.93 \times 10^3 A_{st} + 9.33 \times 10^6 = 0$

$A_{st}\ min = 204.12\ mm^2$

SPACING:

Assume 8 mm dia bars

1) $S = 50.26 / 204.12 \times 1000 = 250$ mm

2) $3 \times d = 3 \times 130 = 390$ mm

3) 300 mm

Provide 8 mm Ø bar at spacing 250 mm c/c

CURTAILMENT:

Alternated bars are curtailed at 0.1leff from face of support

(0.1 x 4.43 = 0.443 m). The full length bars are taken to top and extended from face of support for a distance $0.1l_{eff}$ to take negative.

CHECK FOR SHEAR:

It is sufficient to check for shear along shorter span only

Nominal shear force $V_u = 10.125 \times 4.43 / 2$

$= 22.42$ KN

Nominal shear force $\tau c = V_u/bd$

$= 22.42 \times 10^3 / 1000 \times 130$

$\tau_c = 0.18$ N/mm^2

A_{st} at support $= (a_{st}/2 \times$ spacing$) \times b$

$= (78.54 / 2 \times 300) \times 1000$ (a_{st}= 10 mm dia)

$= 130.9$ mm^2

$\% A_{st} = A_{st}/ bd \times 100$

$= (130.9 / 1000 \times 130) \times 100$

$\%A_{st} = 0.1\ \%$

$\tau_c = 0.29$ N/mm^2 & $k = 1.3$

$K\tau_c = 1.3 \times 0.29$

$K\tau_c = 0.29$ N/mm^2

$\tau_c max/2 = 3.1/2 = 1.55$ N/mm^2

$\tau_c < k\tau_c < \tau_c max/2$

Hence safe in the shear

CHECK FOR DEFLECTION

Assume 10 mm dia

$Ast_{pro} = (a_{st}/ s) \times b = (78.54 / 300) \times 1000$

$= 261.8$ mm^2

% of steel $= 100\ A_{st}/ bd$

$= 100 \times 261.8 / 1000 \times 130$

$= 0.20\ \%$

$fs = 0.58 \times f_y A_{streq} / A_{stpro}$

$= 0.58 \times 415 \times 231.20 / 261.8$

$= 240$

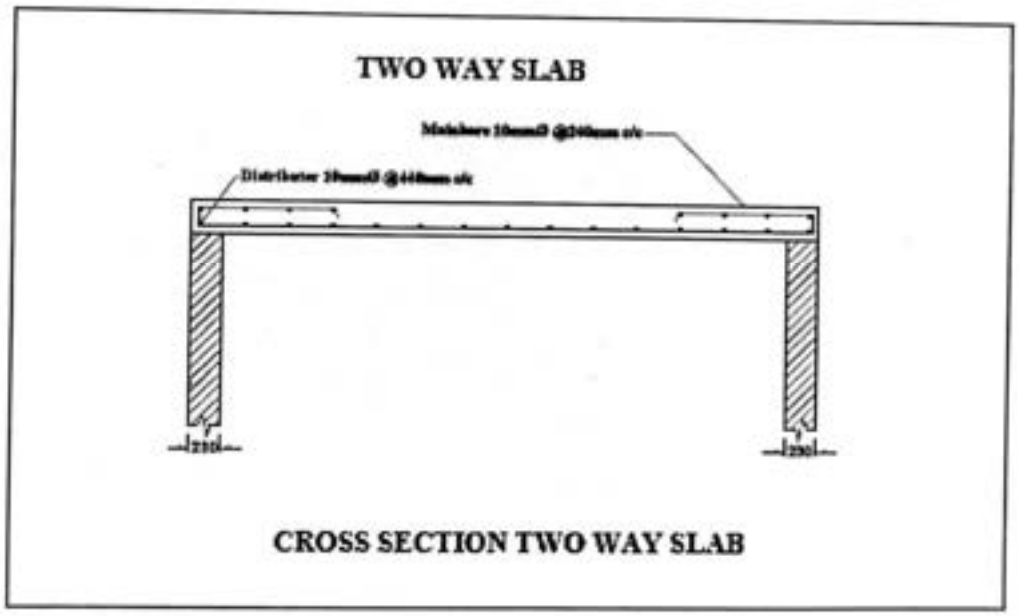
M.F =1.8

d_{avi} = span / (B_V x MF)

$= 4430 / 32 \times 1.8 = 80$ mm

$d_{req} < d_{pro}$

Hence Design Is Safe



5.2 DESIGN OF SIMPLY SUPPORTED BEAM FOR BED ROOM 2

AVAILABLE DATA:

Center to center distance l_{eff}= 5.03 m

B = 300 mm, d = 360 mm & D = 400 mm (assumption)

F_y = 415 N/mm^2 & f_{ck} = 25 N/mm^2

Q=3.45 & % A_{st} = 1.197 %

LOAD CALCULATION:

Self weight of beam = b x D x unit wt

= 0.3 x 0.4 x 25 = 3.0 KN/m

Slab floor finish = perpendicular distance x tk x unit wt

= 2.4 x 0.05 x 20 = 2.4 KN/m

Slab self wt = 2.4 x 0.15 x 25 = 9 KN/m

Wall load = 0.23 x 3.0 x 19 = 13.11 KN/m

Total load = 27.51 KN/M

Factored load = 27.51 x 1.5 F_d= 42 KN/m

FACTORED MOMENT

$M_u = (F_d \times l_{eff}^2)/8 = (42 \times 5.03^2)/8$

M_u = 132.83 KNm

SIZE OF BEAM

Equating $M_u = M_u lim$

$M_u = Q_u \times b \times d^2$ (b=2/3d)

$d = 3 \times M_u / 2 \times Q_u)^{1/3}$

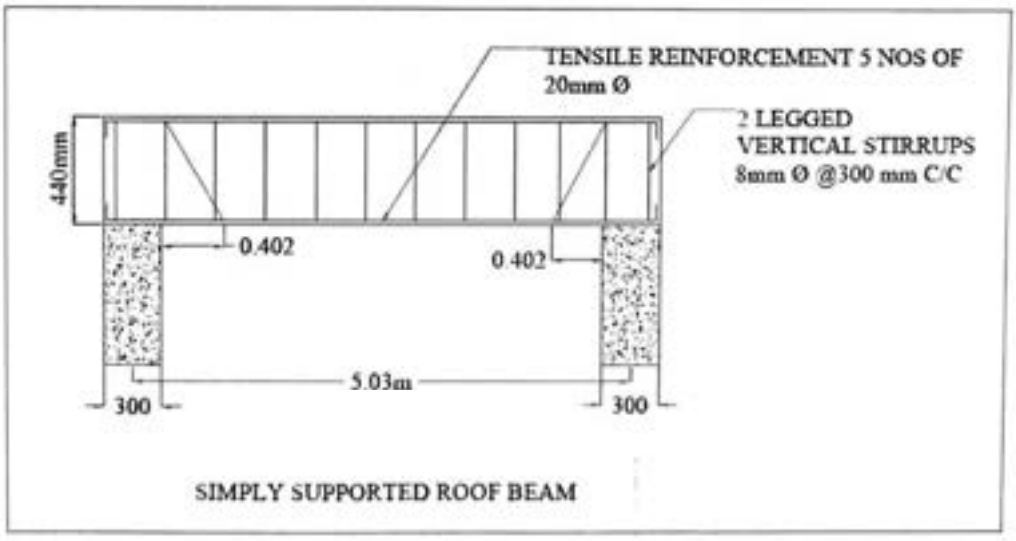
= 150 mm < 360 mm

Hence It Is Safe



SIMPLY SUPPORTED ROOF BEAM

5.3 DESIGN OF LINTEL FOR DOORS AND WINDOWS OPENING

AVAILABLE DATA:

Size of lintel = 230 mmx150 mm

Wall base = 230 mm

Assuming clear cover of 25 mm and 12 mm dia bars

d = 150-25-12/2 = 119 mm

EFFECTIVE SPAN:

Clear span + d = 1.5 + 0.119

l_{eff}= 1.619 m

Height of masonry above the opening = 1.2 m

Height of masonry above the lintel = 1.2 -0.15

= 1.05 m

0.866 x ht = 0.866 x 1.2 = 1.04 m

L_{eff}> 0.86 x l

LOADING CALCULATION:

Self weight of lintel= 1 x 0.23 x 0.15 x 25 = 0.863 KN/m

Weight of masonry = 1 x 0.23 x 1.05 x 19 = 4.588 KN/m

Total weight, W = 5.45 KN/m

Factored load = W x 1.5 = 5.45 x 1.5

= 8.175 KN/m

FACTORED MOMENT

$M_u = F_d \times l_{eff}^2 / 8$

$= 8.175 \times 1.919^2 / 8$

M_u= 3.335 KNM

AREA OF STEEL:

$M_u = 0.87 f_y A_{st} d (1- f_y A_{st} / f_{ck} bd)$

$3.34 \times 106 = 0.87 \times 415 \times A_{st} \times 119(1- 415 \times A_{st} / 25 \times 1000 \times 119)$

$5.99\ A_{st}^2 - 42.96 \times 103\ A_{st} + 3.34 \times 106 = 0$

$A_{st}min = 78.60$ mm2

Provide 2 nos of 10 mm dia bars at bottom and 2 nos of 8 mm dia bars at top as hanger bars

5.4 DESIGN OF SUNSHADE OVER DOORS & WINDOWS OUTSIDE

AVAILABLE DATA:

$f_{ck} = 25\ N/mm^2$

$f_y = 415\ N/mm^2$

Projection = 600 mm

Sunshade thickness D = 50 mm & d = 32 mm

DESIGN CONSTANT:

Basic value = 32

$Q_u = 3.45$

.LOAD CALCULATION:

Consider 1m width of sunshade

Live load = 1 x 0.6 x 0.75= 0.45 KN

Self weight of sunshade = 1 x b x D x unit weight

= 1 x 0.6 x 0.05 x 25

= 0.75 KN

Total load = 1.2 KN/m

Design load = 1.2 x 1.5 = 1.8 KN/m

FACTORED MOMENT:

$M_u = F_d \times L_{eff}/2$

$= 1.8 \times 0.6/2$

$= 0.54$ KNm

$M_u = 0.54 \times 10^6$ N.mm

DEPTH REQUIRED:

$M_u = M_{ulim}$

$$d = \sqrt{\frac{Mu}{Qub}}$$

$$= \sqrt{\frac{240}{3.45 \times 1}}$$

d_{req} = 13 mm & D = 13+15+6/3 = 31 mm

$d_{req} < d_{pro}$

Adopt greater value further design

d = 32 mm & D = 50 mm

TYPE OF SECTION:

$M_{u\ limit} = Q_u b\ d^2$

$= 3.45 \times 1000 \times 32^2$

$= 3.53 \times 10^6$ N.mm^2

$M_u < Mu_{limit}$ Hence it is under reinforced section

MAIN REINFORCEMENT:

$M_u = 0.87\ f_y A_{st}\ d\ (1 - f_y A_{st} / f_{ck} bd)$

$0.54 \times 10^6 = 0.87 \times 415 \times A_{st} \times 32\ (1 - 415 \times A_{st} / 25 \times 1000 \times 32)$

$5.99 A_{st}^2 - 11.55 \times 10^3 A_{st} + 0.54 \times 10^6 = 0$

$A_{st}min = 47.95$ mm^2

SPACING:

Assume 6 mm dia bars

1) $S = a_{st}/A_{st} \times b = 28.27/47.95 \times 1000$

$= 590$ mm

2) 3d = 3 x 32= 96 mm

3) 300 mm c/c

Provide 6 mm dia bars @ spacing 95 mm c/c distance.

DISTRIBUTOR REINFORCEMENT

A_{st} min= 0.12 / 100 x B x D

$= 0.12 /100 \times 1000 \times 50$

$= 60 \text{ mm}^2$ per meter width

$= 60 \times 0.6 = 36 \text{ mm}^2$

SPACING:

Assume 6mm dia of distribution steel

1) $S = a_{st} / A_{st}\text{min} \times b = (28.27/36) \times 1000$

$= 785$ mm

2) $5d = 5 \times 32 = 160$ mm

3) 450 mm

Provide 6 mm dia bars @ spacing 160 mm c/c

DEVELOPMENT LENGTH:

$L_d = 0.87 f_y \text{ dia}/4\tau_{bd}$

$= 0.87 \times 415 \times 6 / (4 \times 1.4)$

$= 386.83$ mm

$L_d$required inside the support = 386.83 mm say 385 mm.

CHECK FOR SHEAR:

It is sufficient to check for shear along shorter span only

Nominal shear force $V_u = 1.2$ KN

Nominal shear force $\tau_v = V_u/bd$

$= 1.2 \times 10^3/1000 \times 32$

$\tau_v = 0.037$ N/mm2

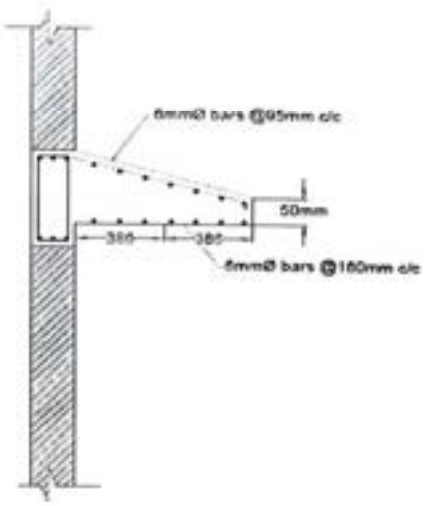
$K\tau_c = 0.37 \text{ N/mm}^2$

$\tau_c\text{max}/2 = 3.1/2 = 1.55 \text{ N/mm}^2$

DESIGN OF SUNSHADE



CROSS SECTION OF SUNSHADE

5.5 DESIGN OF SQUARE COLUMN TO SUPPORT BEAMS

AVAILABLE DATA:

Size of column = 300 X 300 mm

f_{ck} = 25 N/mm^2

f_y = 415 N/mm^2

LOAD CALCULATION:

SLAB:

Wt of slab (1) = L x B x D x unit wt

= 2.15 x 2.4 x 0.15 x 25 = 19.35KN

Wt of slab ff (1) = L x B x D x unit wt

= 2.15 x 2.4 x 0.05 x 20 = 5.16 KN

Live load (1) = 2.0 x 2.15 x 2.40 = 10.32 KN

BEAM

Beam (1) = L x B x D x unit wt

= 2.15 x 0.3 x 0.4 x 25 = 6.45 KN

Beam (2) = 2.4 x 0.3 x 0.40 x 25 = 7.2 KN

WALL

Wall load (1) = L x B x H x unit wt

= 2.15 x 0.23 x 3.0 x 19 = 28.20 KN

Wall load (2) = 2.40 x 0.23 x 3.0 x 19 = 31.46 KN

COLUMN

Self weight of column = L x B x H x unit wt

= 0.3 x 0.3 x 3.0 x 25 = 6.75 KN

Sum of all above loads = 114.90 KN

No of floor consideration = 115 x 1 = 115 KN

DESIGN LOAD:

P_u = W x 1.5 = 115 x 1.5

P_u = 172.50 KN

AREA OF COLUMN

A_g = l x b = 300 x 300 = 90 x 10^3 mm^2

SLENDERNESS RATIO

S.R = L_{eff} / b

= 3000 / 300

S.R = 10 < 12

Slenderness ratio is less than 12

Hence short column

MINIMUM ECCENTRICITY

e_{min} = L_{eff}/500+b/30

= 3000/500 + 300/30

e_{min} = 16 mm

e_{max} = 0.05 b

= 0.05 x 300

= 15 mm

LONGITUDINAL REINFORCEMENT

Let assume $A_{sc} = 1\% A_g$

$= 0.01 A_g$

$= 0.01 \times 90 \times 10^3$

$= 900 \text{ mm}^2$

Area of concrete $A_c = A_g - 0.01 A_g = 0.99 A_g$

$= 0.99 \times 90 \times 10^3$

$= 89.10 \times 10^3$

$P_u = 0.4 f_{ck} A_c + 0.67 f_y A_{sc}$

$P_u = 0.4 \times 25 \times 89.10 \times 10^3 + 0.67 \times 415 \times 900$

$P_u = 1140$ KN

Say $P_u = 1140$ KN > 172.50 KN

Hence safe

$\% A_{sc} = 100 A_{sc}/A_g$

$= 100 \times 900 / (90 \times 10^3)$

$\% A_{sc} = 1\% > 0.8\% < 6\%$

HENCE OK

Let us provide 5 nos of 16 mm dia bars

$Asc = 5 \times \pi \times 16^2/4 = 1005.30 \text{ mm}^2$

COVER

Clear cover shall be greater of

a) 40 mm

b) Dia = 16 mm

Provide a clear cover of 40 mm

SPACING

1) Longer side S = 300- (40+40+16/2+16/2) / 2

S = 252 mm < 300mm

TRANSVERSE REINFORCEMENT

MINIMUM DIAMETER

1) 1/4 x dia = 1/4 x 16 = 4 mm

2) Not less than 6 mm

PITCH

1) LLD = 300 mm

2) 16 x 16 = 260 mm

3) 300 mm

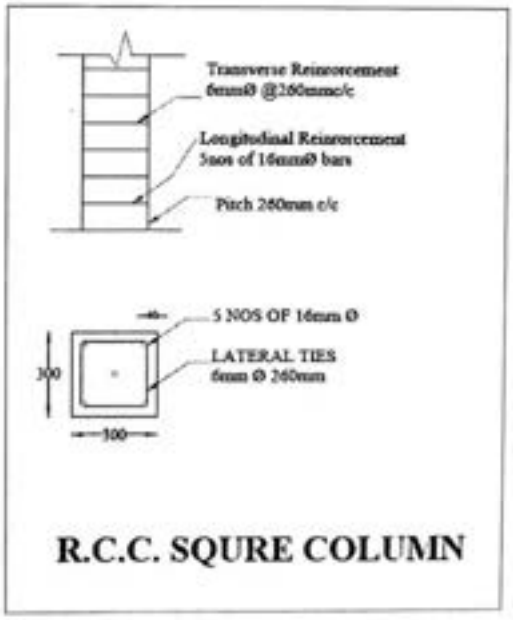
Provide 6 mm dia laterals at 260 mm c/c

RESULT

Size of column = 300 x 300 mm

Longitudinal reinforcement = 5 nos of 16 mm dia bars

Transverse reinforcement = 6 mm dia at 260 mm c/c



R.C.C. SQURE COLUMN

Provide 2 legged 8 mm dia stirrups @ 270 mm c/c.

CHECK FOR STIFFNESS:

%Ast @ mid span = 1357.16 x 100 / 300 x 360

= 1.25 %

Stress in tension reinforcement,

Fs = 0.58 Fy (Ast_{req} / Ast_{pro})

= 0.58 x 415 x (694.57 / 1357.16)

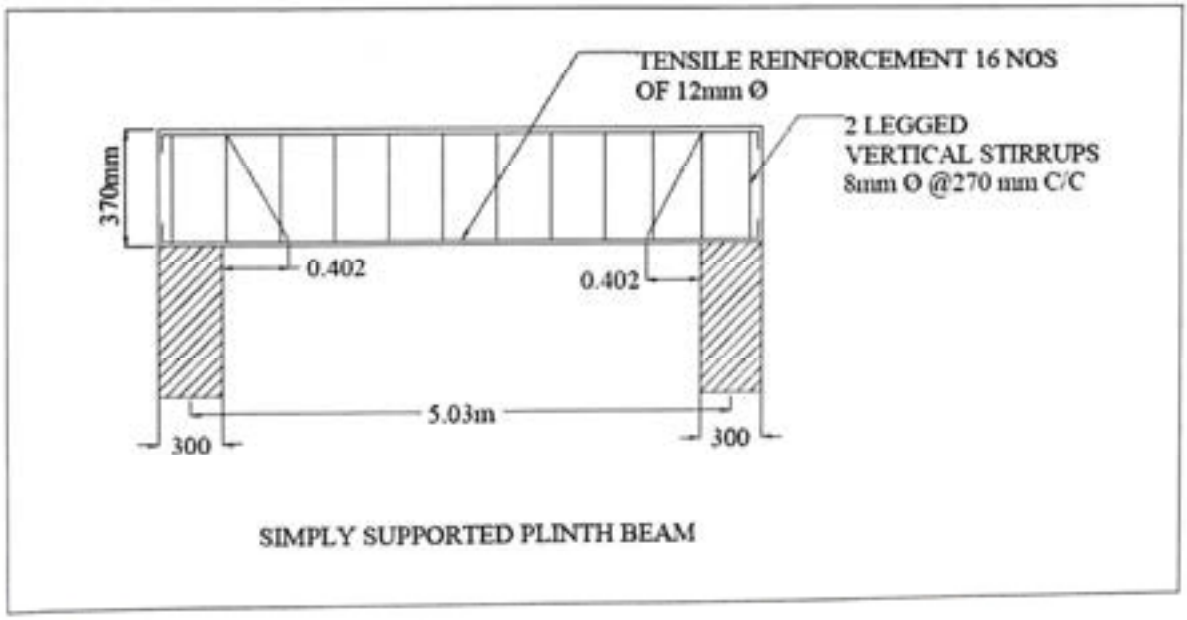
= 120 Curve

MF = 1.5

d = 5030 / 32 x 1.5

= 110 mm < 360 mm

Hence it is safe



SIMPLY SUPPORTED PLINTH BEAM

5.7 DESIGN OF DOG LEGGED STAIR CASE

AVAILABLE DATA

Vertical height of floor = 3000 mm

Rise = 150 mm & thread = 300 mm

Size of room = 3.5 x 1.5 m

SIZES OF STAIRCASE

No of riser = height/rise = 3000/150 = 20 nos

No of flight = 2

Riser per flight = 20/2 =10 nos

No of tread = 10-1 = 9 nos

Length of going = thread x nos of tread

= 300 x 9 = 2700 mm

Width of landing = (3500-2700)/2 = 400 mm

EFFECTIVE SPAN

L_{eff} = 2.7+0.4+0.4+0.23/2+0.23/2

= 3.73 m

Thickness of waist slab = span/20 = 3730/20 = 190

Overall depth D = 190 mm

d = 165 mm

LOAD CALCULATION

Assume waist slab thickness 150 mm

Self weight of waist slab = 1 x 0.15 x 25 (sloped area)

Ws = 3.75 KN/m

Plain area = Ws x $[(R^2 + T^2)/T^2]^{1/2}$

= 3.75 x $[(0.15^2 + 0.3^2)/ 0.3^2]^{1/2}$

= 2.795 KN/m

Weight of steps per m^2 = 0.5 x 0.15 x 0.3 x 25

= 0.56 KN/m

Load of step per meter length = 0.56 x 1000/300

= 1.86 KN/m

Finishes = 0.53 KN/m

Total dead load = 2.795+1.86+0.53 = 5.185 KN/m

Service live load (liable for overcrowding) = 5 KN/m^2

Total service load = 5.185+5 = 10.185 KN/m

Factored load = 10.185 x 1.5 = 15.3 KN/m

FACTORED MOMENT:

M_u = Fd x $leff^2/8$ = 15.3 x $3.73^2/8$

= 26.6 KNM

$M_u = 26.6 \times 10^6$ $N.mm^2$

DEPTH REQUIRED:

$M_u = M_{ulim}$

$$d = \sqrt{\frac{Mu}{Qub}}$$

$$= \sqrt{\frac{26600}{3.45 \times 1}}$$

d_{req} = 87.8 say 90 mm <dpro

$d_{req} < d_{pro}$

Adopt greater value further design

d = 165 mm & D = 190 mm

TYPE OF SECTION:

$M_{u\ limit} = Q_u x b \times d^2$

$= 3.45 \times 1000 \times 165^2$

$= 93.92 \times 10^6$ $N.mm^2$

$M_u < Mu_{limit}$

Hence it is under reinforced section

MAIN REINFORCEMENT:

Mu = 0.87 fyAst d (1- fyAst / fckbd)

26.6 x 106 = 0.87 x 415 x Ast x 165 (1- 415 x Ast / 25 x 1000 x 165)

5.99Ast2 – 59.57 x 103Ast + 26.6 x 106 = 0

Ast min = 468.61 mm2

SPACING:

Assume 10 mm dia bars

1) S = ast / Ast x b = 78.54/468.61 x 1000

= 160 mm

2) 3d = 3 x 165 = 495 mm

3) 300 mm c/c

Provide 10 mm dia bars @ spacing 160 mm c/c distance.

DISTRIBUTOR REINFORCEMENT

A_{st} min= 0.12 / 100 x B x D

= 0.12 /100 x 1000 x 190

= 228 mm^2

SPACING:

Assume 8 mm dia of distribution steel

1) S = a_{st} /A_{st}min x b= 50.26/228 x 1000

= 220 mm

2) 5d = 5 x 165 = 825 mm

3) 450 mm

Provide 8 mm dia bars @ spacing 220 mm c/c

CURTAILMENT:

Alternated bars are curtailed at 0.1leff from face of support (0.1 x 3.73=0.373 m) . The full length bars are taken to top and extended from face of support for a distance 0.1leff to take negative.

CHECK FOR SHEAR:

It is sufficient to check for shear along shorter span only

Nominal shear force V_u = 15.3 x 3.73/2

= 28.53 KN

Nominal shear force $\tau_v = V_u/bd$

$= 28.53 \times 10^3/1000 \times 165$

τ_v= 0.17 N/mm2

A_{st} at support = (a_{st} / 2 x spacing) x b

= (78.54/2 x 160) x 1000 (a_{st}=10 mmdia)

= 245.43 mm^2

% A_{st} = $A_{st}/bd \times 100$

= (245.43/1000 x 165) x 100

%Ast= 0.14 %

τ_c = 0.29 N/mm^2 & K=1.22

$K\tau_c$ = 1.22 x 0.29

$K\tau_c$ = 0.35 N/mm^2

$\tau_c max/2 = 3.1/2 = 1.55$ N/mm^2

$\tau_v < K\tau_c < \tau_c max/2$

Hence safe in the shear

CHECK FOR DEFLECTION

Assume 10 mm dia

$A_{stpro} = (a_{st}/s) \times b = (78.54/160) \times 1000$

= 490.87 mm^2

% of steel = $100A_{st}/bd$

$= 100 \times 490.87 /1000 \times 165$

= 0.2 %

$f_s = 0.58 \times f_y Ast_{req}/Ast_{pro}$

$= 0.58 \times 415 \times 468.61/490.87$

= 240

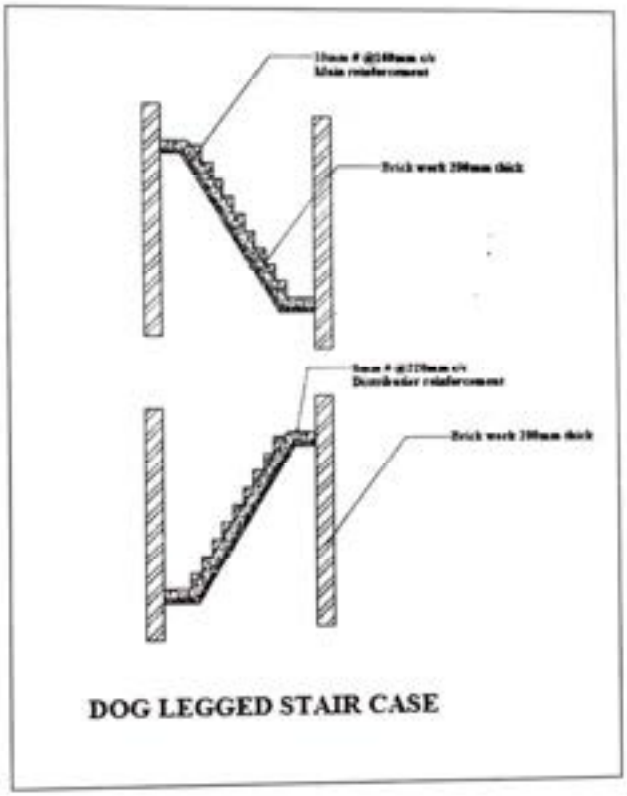
M.F = 1.4 (by using 240 curve in graph)

d_{avi}= span/(B_V x MF)

= 3730/32 x 1.4 = 83.25 mm

$d_{req} < d_{pro}$

Hence design is safe



DOG LEGGED STAIR CASE

5.8 DESIGN OF ISOLATED SQUARE FOOTING FOR SQUARE COLUMN

AVAILABLE DATA:

Size of column = 300 x 300 mm

Safe bearing capacity = 200 KN/m^2

f_{ck} = 30 N/mm^2

f_y = 415 N/mm^2

SIZE OF FOOTING

Axial load of footing = 115 KN

Assume the self wt of footing as10%of the column load

W1 = 10/100 x 115

= 11.5 KN

Total load on soil = 115 + 11.5 = 126.5 KN

Area of footing required = total load /sbc

= 130 / 200

= 0.65 m^2

Since it is a square column

B x L = 0.65 m^2

B x (B) = 0.65 m^2

B^2 = 0.65

= $\sqrt{0.65}$ = 0.806

B = 0.80 & L= 0.80 m

Area of footing = 0.80 x 0.80 = 0.64 m^2

NET UPWARD DESIGN PRESSURE

Fo = 115 x 1.5 / 0.64

= 270 KN/m^2

PROJECTION OF FOOTING

Projection of footing from face of column = 0.80 - 0.3 / 2 = 0.65 m

FACTORED MOMENT

Maximum factored moment occurs at the face of column for design purpose consider over hang on both sides

M_u= fo x projection area x prj.dis/2

= 270 x 0.80 x 0.65 x 0.65 / 2

= 45.63 x 10^6

DEPTH REQUIRED FOR FOOTING

$$d_{req} = \sqrt{\frac{Mumax}{Qu \times b}}$$

$$dreq = \sqrt{\frac{45630}{4.14 \times 0.80}} = 117.37$$

Say d_{req} = 150 mm

Considering the effect of shear provide an effective depth of 300 mm practically the effective depth of 150 mm may not sufficient to take care off shear , hence let us increase the depth two time.

d = 300 mm

Provide 50mm as effective cover

D = 300 + 50

D = 350 mm

TENSION REINFORCEMENT

M_U= 0.87 $f_y A_{st}$ d (1- $f_y A_{st}$ / f_{ck}bd)

45.63 x 10^6 = 0.87 x 415 x A_{st} x 300 (1- 415 x A_{st} / 30 x 800 x 300)

6.24 A_{st}^2 – 108.315 x $10^3 A_{st}$ + 45.63 x 10^6 = 0

A_{stL} = 432.02 mm^2

A_{stmin} = 0.12/100 x (b x D)

= (0.12/100) x 800 x 350

Ast_{min} = 336 mm^2

$a_{st} = \pi \times 10^2/4 = 78.54\ mm^2$

NOS = A_{stL} / a_{st} = 432.02 / 78.54 = 6 nos

Provide 6 nos of 10 mm dia bars in long direction at uniform spacing

$A_{st} = 6 \times \pi \times 10^2/4 = 471.23\ mm^2$

CHECK FOR DEVELOPMENT LENGTH

L_d=0.87 Fyxdia / 4 x τ_{bd}=0.87 x 415 x 10/(4 x 1.5)

L_d= 601.75 mm

Length of bars beyond the face of column in long direction

800 -50= 750 mm >601.75 mm

Hence ok

.Hooks are not necessary at end of bars.

CHECK FOR SHEAR

TRANSVERSE SHEAR

V_u= fo x length x (0.65 -0.3)

= 270 x 0.80 x 0.35

= 75.6 KN

$\tau_v = V_u/bd = 75.6 \times 10^3 / 800 \times 300$

$\tau_v = 0.32\ N/mm^2$

$\%A_{st} = 100A_{st} / bd = 100 \times 471.23 / (800 \times 300)$

= 0.20 %

$\tau_c = 0.37\ N/mm^2$

$K\tau_c = 1 \times 0.37 = 0.37\ N/mm^2$

$\tau_v < K\tau_c$ Safe in shear

CHECK FOR PUNCHING SHEAR

At d/2 around the column. The critical section for punching shear is at a distance of d/2= 300 /2= 150 mm

From the face of column around

Side of section = (150 + 300 + 150) x (150 + 300 + 150)

= 600 x 600 mm

PUNCHING SHEAR ACROSS SECTION

Vz = fo x (outer area – inner cutting area)

= 270 x (0.8 x 0.80 – 0.6 x 0.6)

$Vz = 75.6 \times 10^3$ N

NOMINAL SHEAR STRESS

$\tau z = 75.6 \times 10^3 / 2(600 + 600) \times 300$

$\tau z = 0.105$ N/mm^2

PERMISSIBLE SHEAR STRESS IN CONCRETE

$\tau_{cz} = K s \tau cz$

Bc = 300 / 300 = 1.0

Ks = 0.5 + 1.0 = 1.50 limited to 1

$\tau_{cz} = 0.25 \sqrt{fck} = 0.25 \sqrt{30} = 1.37$

$K s \tau cz = 1 \times 1.37 = 1.37$ N/mm^2

$\tau z < K s \tau cz$

safe in punching shear .

Hence ok

CHECK FOR BEARING STRESS

Size of the base of frustum of pyramid= (b+4d) x (D+4d)

= (300 + 4 x 300) x (300 + 4 x 300)

= 1500 x 1500

But limited to 1500 x 1500 mm

Supporting area $A_1 = 0.80 \times 0.80 = 0.64$ m^2

Loaded area $A_2 = 0.30 \times 0.30 = 0.09\ m^2$

$\sqrt{A1/A2} = \sqrt{0.64/0.09} = 2.67$ but restricted to 2

Permissible bearing stress = 0.45 x fck x $\sqrt{A1/A2}$

$= 0.45 \times 30 \times 2 = 27\ N/mm^2$

Actual bearing stress $= \frac{Pu}{Area\ of\ column} = \frac{115 \times 1.5}{0.30 \times 0.30}$

$= 1.91\ N/mm^2$

$1.91 < 27$

Hence safe

CHECK FOR SBC OF SOIL

Column load = 115 KN

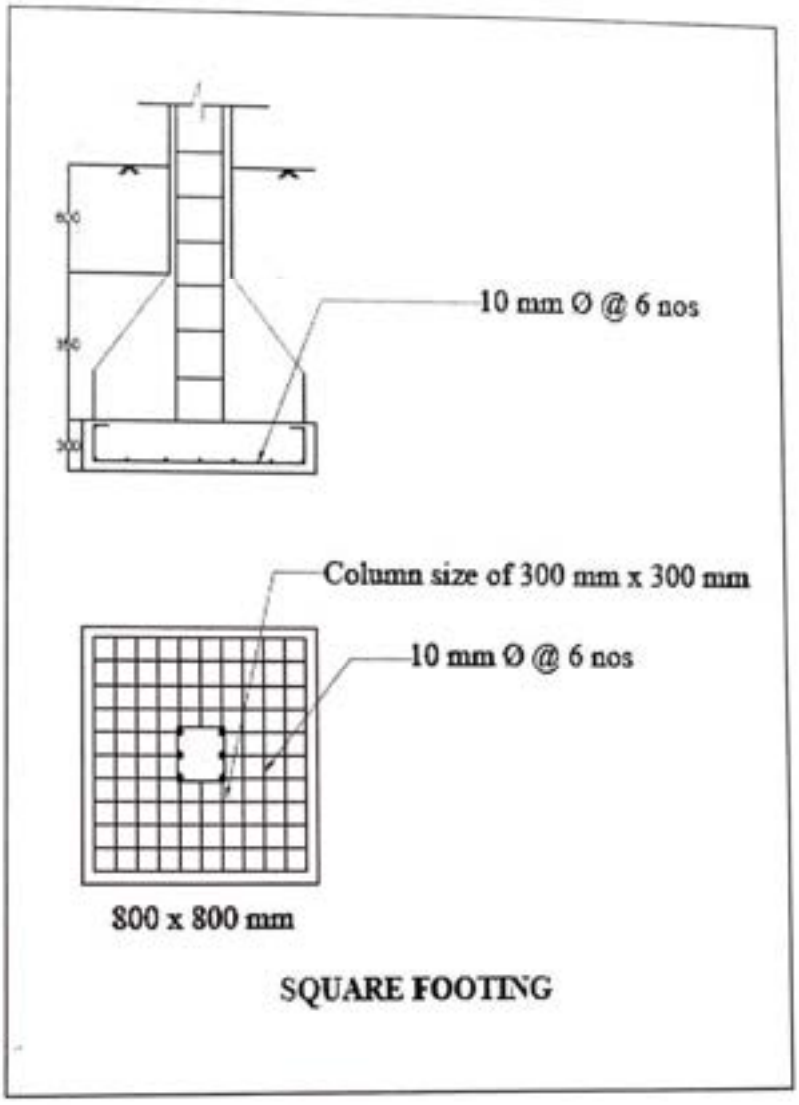
Weight of footing = 0.80 x 0.80 x 0.35 x 25 = 5.6 KN

Total load on soil = 125 KN

Pressure on soil = 125 / (0.80 x 0.80) = 195.31 KN/m^2

195.31 $KN/m^2 <$ 200 KN/m^2

Hence safe



SQUARE FOOTING

CHAPTER 6

STAAD REPORT

STAAD or (STAAD.Pro) is a structural analysis and design computer program originally developed by Research Engineers International in Yorba Linda, CA. The commercial version STAAD.Pro is one of the most widely used structural analysis and design software. It supports several steel, concrete and timber design codes.

CONCLUSION

Through our project we conclude that application of software in civil industry plays important role in our study. In our project Residential building with triple bed rooms we adopt limit state method for analysis and design of our structure.

Time taken for doing this project is very less due to the application of the software. We bring extra accuracy in dimension and analysis part through our project. Hence we conclude that application software in our filed is quite good and comprehensive for further study of structural parameter.

ABSTRACT

A proposal for home control using voice via Google Assistant. There are home automation technologies introduced over these years from ZigBee automation, Amazon Echo, Google home etc., It describes the implementation of such a system. The system is implemented using ordinary household appliances Natural language voice commands are given to the Google Assistant and with the help of IFTTT (If This Then That) application and the Adafruit the commands are decoded and then sent to the microcontroller, the microcontroller in turn controls the relays connected to it as required, turning the device connected to the respective relay On or OFF as per the users request to the Google Assistant. The microcontroller used is NodeMCU (ESP8266) and the communication between the microcontroller and the application is established via Wi-Fi (Internet).

CHAPTER 1
INTRODUCTION

1.1 OVERVIEW

Home, it is the place where one fancies or desires to be after a long tiring day. People come home exhausted after a long hard working day. Some are way too tired that they find it hard to move once they land on their couch, sofa or bed. So any small device/technology that would help them switch theirs lights on or off, or play their favourite music etc. on a go with their voice with the aid of their smart phones would make their home more comfortable.

Moreover, it would be better if everything such as warming bath water and adjusting the room temperature were already done before they reach their home just by giving a voice command. So, when people would arrive home, they would find the room temperature, the bath water adjusted to their suitable preferences, and they could relax right away and feel cosier and rather, feel homelier. Human assistants like housekeepers were a way for millionaires to keep up their homes in the past. Even now when technology is handy enough only the well to do people of the society are blessed with these new smart home devices, as these devices costs are a bit high. However, not everyone is wealthy enough to be able to afford a human assistant, or some smart home kit. Hence, the need for finding an inexpensive and smart assistant for normal families keeps growing. It uses the Google Assistant, the IFTTT Web interface, the Adafruit Web Interface and the NodeMCU microcontroller as the major components along with a relay board comprising of 4/8 relays along with ULN 2803 IC. Natural language voice is used to give commands to the Google Assistant. All of the components are connected over the internet using Wi-Fi which puts this system under the IoT.

1.2 OBJECTIVES

The aim is to provide a cheap home automation system to assist common man's life to make his schedule more efficient and help conserve energy; it will also be of great use to handicapped and elderly members of our society.

The system has two modules in totality; the first module consists of control of lights, blinds and fans which will be switched on and off using voice commands on Google assistant. The second module consists of control of common household appliances such as television, projector, air conditioners etc. Intend to attach four loads in this work and the control of the appliances will be done using two methods in particular; they are App and voice control. Voice control can easily be achieved on an Android mobile using Google Assistant.

1.3 PROBLEM STATEMENTS

The main problems that a home automation system faces are high cost of the system, strenuous configuration and set up process and security of the system. This developed system will be much cheaper than the available systems in the market and cover the control of most of the commonly used home appliances in a house using an Android App and voice control using Google Assistant on the user's mobile. The system is wireless and will be using Bluetooth as well as Wi-Fi to allow the user to control various appliances using their mobile phones, personal computers/ Laptops etc. It has never been easier or more affordable to purchase and install smart devices and home control systems. The drawback, however, is that systems are regularly being installed incrementally without a central control point. And that can lead to home automation problems.

CHAPTER 2
LITERATURE SURVEY

2.1 Smart Home Using Wi-Fi

NiharikaShrotriya et al., [1] proposed the system allows the people think about home automation, most of them may imagine living in a smart home: One remote controller for every household appliance, cooking the rice automatically, starting air conditioner automatically, heating water for bath automatically and shading the window automatically during night. To some extent home automation equals to smart home. They both bring out smart living condition and make our life more convenient and fast. Early home automation began with labour-saving machines. Self-contained electric or gas powered home appliance became viable in the 1900s with the introduction of electric power distribution led to the introduction of washing machine (1904), water heater (1889), refrigerator, sewing machines, dishwashers and clothes dryers. As per the survey currently there exists system neither at cheaper rates nor easy to handle. Various systems are hard to install, difficult to use and maintain.

2.2 Development of Internet Based System:

Tan, et al., [2] proposed the development of an Internet-based system to allow monitoring of important process variables from a distributed control system (DCS). The hardware and software design considerations which enable the user to access the process variables on the DCS, remotely and effectively rent designations.

The use of speech to interact remotely with the home appliances to perform a particular action on behalf of the user. The approach is inclined for people with disability to perform real-life operations at home by directing appliances through speech. Voice separation strategy is selected to take appropriate decision by speech recognition. It is one of the difficult system to process it.

2.3 A System for Smart-Home Control of Appliances Based on Time and Speech Interaction:

S. M. AnamulHaque et al., [3] proposed a system entitled "A System for Smart-Home Control of Appliances Based on Time and Speech Interaction" that controls the home appliances using the personal computer. The system is developed by using the Visual Basic 6.0 as programming language and Microsoft voice engine tools for speech recognition purpose. Appliances can be either controlled by timer or by voice command. The remote monitoring through mobile phone involving the use of spoken commands. The spoken commands are generated and sent in the form of text SMS to the control system and then the microcontroller on the basis of SMS and it takes the difficult for decision a particular task.

2.4 Home Automation and Security using Android ADK:

DeepaliJavale et al., [4], proposed the design of home automation and security system using android ADK. The design is based on Standalone embedded system board android ADK (Accessory Development Kit) at home. Home appliances are connected to the ADK and communication is established between the ADK and android mobile device or tablet. The home appliances are connected to the input/output ports of embedded system board and their status is passed to ADK. They have developed an authentication to the system for authorized person to access home appliances. The device with high cost and scalable to less modification to the core is used. It presents the design and implementation of automation system that can monitor and control home appliances via android phone or tablet.

2.5 Safe and Secure PIC Based Remote Control Application for Intelligent Home:

E. Yavuz et al., [5] proposed the secure PIC based remote control system for intelligent houses has been presented. With this implemented system, it is possible to safely control electricity operated domestic devices by the help of public or mobile phones from any places all over the world. Developed remote control device has been optically and electrically isolated to secure the system.

2.6 Bluetooth Based Home Automation System:

N. Sriskanthan et al., [6] proposed the Journal of Microprocessors and Microsystems, the "Home Automation" concept has existed for many years. The terms "Smart Home", "Intelligent Home" followed and has been used to introduce the concept of networking appliances and devices in the house. Home automation Systems (HASs) represents a great research opportunity in creating new fields in engineering, architecture and computing (Huidobro and Millan, 2004). HASs becoming popular nowadays and enter quickly in this emerging market. However, end users, especially the disabled and old aged due to their complexity and cost, do not always accept these systems. Due to the advancement of wireless technology, there are several different of connections are introduced such as GSM, WIFI, ZIGBEE, and Bluetooth. Each of the connection has their own unique specifications and applications. Among the four popular wireless connections that often implemented in HAS project, Bluetooth is being chosen with its suitable capability. Bluetooth with globally available frequencies of 2400Hz is able to provide connectivity up to 100 meters at speed of up to 3Mbps depending on the Bluetooth device class.

2.7 Home Automation Using Internet of Things:

Kusuma [7] proposed a Home Automation system that employs the integration of multi-touch mobile devices, cloud networking, wireless communication, and power-line communication to provide the user with remote control of various lights and appliances within their home. This system uses a consolidation of a mobile phone application, handheld wireless remote, and PC based program to provide a means of user interface to the consumer.

The main objective is to design and implement a control and monitor system for smart house. Smart house system consists of many systems that controlled by LAB VIEW software as the main controlling system. Also, the smart house system was supported by remote control system as a sub controlling system. The system also is connected to the internet to monitor and control the house equipment's from anywhere in the world using LAB VIEW.

Deepali Javale [4], also proposed the prime objective is to assist handicapped/old aged people. It gives basic idea of how to control various home appliances and provide a security using Android phone/tab. The design consists of Android phone with home automation application, Arduino Mega ADK. User can interact with the android phone and send control signal to the Arduino ADK which in turn will control other embedded devices/sensors.

A new design for the smart home using the wireless sensor network and the biometric technologies. The system employs the biometric in the authentication for home entrance which

enhances home security as well as easiness of home entering process. The structure of the system is described and the incorporated communications are analyzed, also an estimation for the whole system cost is given which is something lacking in a lot of other smart home designs offers. WB-SH is designed to be capable of incorporating in a building automation system and it can be applied to offices, clinics, and other places. It ends with an imagination for the future of the smart home when employs the biometric technology in a larger and more comprehensive form. It ends with an imagination for the future of the smart home when employs the biometric technology in a larger and more comprehensive form.

CONCLUDING REMARKS:

The various literature survey has published here which the systems are hard to install, difficult to maintain. The proposed system were not in optimized and user friendly.

Our Proposed system is easily accessible from mobile itself and provides access anywhere from the world and there is no need of any separate interface to run it. Current systems are generally proprietary, closed and user friendly Based on Arduino and low cost home automation system.

CHAPTER 3
SYSTEM ANALYSIS

3.1 EXISTING SYSTEM

The IoT is used in order to control the home appliances where the home appliances are remotely controlled using a web page buttons, where the user have to go to the particular link and from there to press buttons in order to control the home appliance. It involves the control the lighting, heating, ventilation, air conditioning and security, as well as home appliances. Remote or sensors are used for controlling Home devices, Modern systems generally consists of switches and sensors connected to a central hub called a gateway from which the system is controlled with a user interface that is interacted either with a mobile phone software ,tablet, computers or a web interface often but not always via internet cloud services.

To some extent home automation equals to smart home. They both bring out smart living condition and make our life more convenient and fast. Early home automation began with labour-saving machines. Self-contained electric or gas powered home appliance became viable in the 1900s with the introduction of electric power distribution led to the introduction of washing machine water heater refrigerator, sewing machines, dishwashers and clothes dryers. As per the survey currently there exists system neither at cheaper rates nor easy to handle. Various systems are hard to install, difficult to use and maintain. Current systems are generally proprietary, closed and not very user friendly Based on Arduino or GSM or low cost home security system and home automation system.

3.1.1 DISADVANTAGE OF EXISTING SYSTEM

- The operating is difficult.
- A separate web page is required.
- For every switching on and off user want to login into web page.

3.2 PROPOSED SYSTEM

The idea is to integrate the concept of Google Assistant into Arduino and control the appliances in the home that the device is installed. Google recently released an API for Google Assistant, for platforms other than Android, such as Linux and Windows, using Python language.

When the user sends command through Google assistant it first goes to the IFTTT there the given set statements that states he IF THIS THEN THAT can understand this when the architecture

of our system. From there it goes to the Adafruit is cloud service it is like MQTT broker which interacts with the NodeMCU. The Control Unit comprises of the microcontroller- Node MCU and the 4 Channel Relay board. Android device communicates with the microcontroller and sends the desired signal via the internet.

The system has the capabilities to control the following components in user's home and monitor the following alarms: Temperature and humidity Motion Detection Light level and Lights on/off/dim Fan on/off On/off different appliance and also Provide a more user-friendly interaction Various issue are solved like sending notification by providing the data monitoring system so it can be control the sensors data. Very simple and provide interaction with Google assistant.

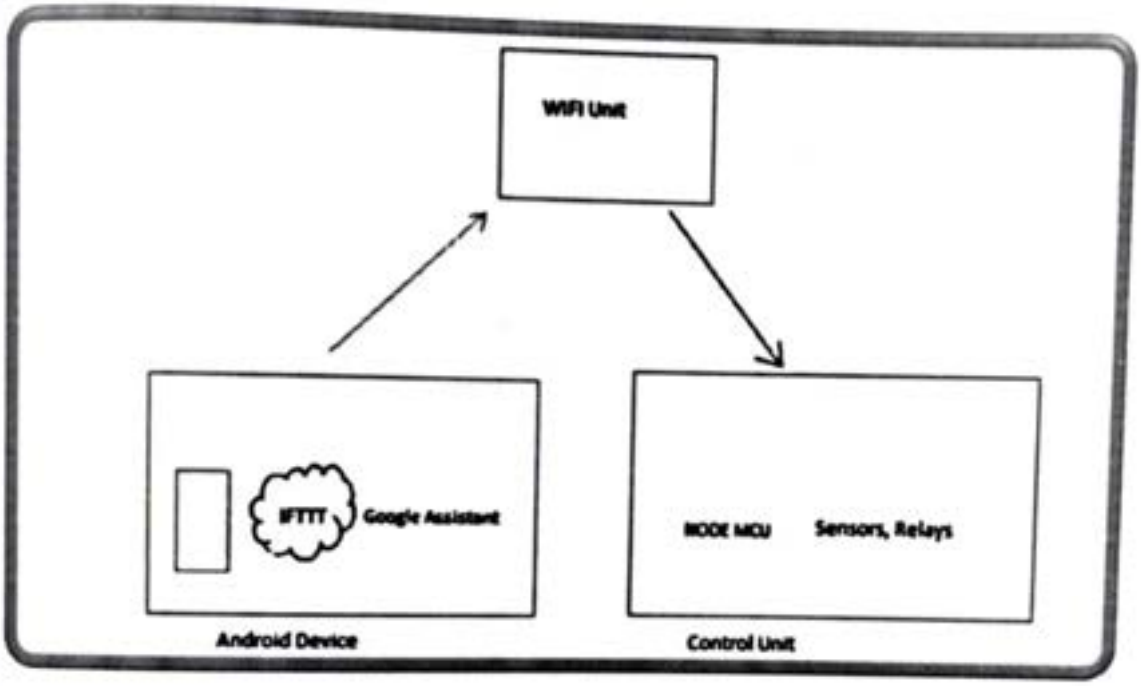

Fig 3.1 Overall Design

The system which has WI-FI as the control unit. It enhances the data from Microcontroller to web interfaces and also from web interfaces to microcontroller. The IFTTT and Google Assistant are used as an android devices and NodeMCU, Sensors, Relay are used as the control unit in the Home control system.

Voice controlled home automation is a step further in easing the control of appliances. This helps the handicapped as well as elderly people to access the home appliances with ease. As technology grows and expands with every single moment, automations have also taken leaps and bounds. Earlier a niche field which was accessible to only a select few, Home Automation is now becoming economically accessible to a much larger market. Through this system is intend to make

home automation economically accessible to every family. An automation system for home which makes use of cloud computing and wireless communication has been studied. This is found to be cheaper. The internet of things is intended to bring everything in the universe under a single framework. This provides greater control of the stuff while updating the user on the status of things. Communication was also made possible through Bluetooth to automate home appliances. New schemes for smarter homes were discussed and advancements were introduced. Home appliances can also be controlled by using RP along with the concept of relay circuit by adopting a web page.

3.2.1ADVANTAGES OF PROPOSED SYSTEM

- System can be easily accessible from mobile itself.
- It provides Access from anywhere the system is connected to server.
- The system no need of any interface for communication. Google assistance is enough.

3.2.2 SYSTEM ARCHITECTURE

The Home Automation system will have about two modules.

- The first module consists of control of lighting, fans etc. using an Android phone App as well as voice commands using Google Assistant.
- The second module consist of control of various heavy power Household appliances such as television, air conditioner, Iron box etc.

Different types of applications using android platform with Wi-Fi can be further developed. In this work a four channel 12V relay is used to connect the appliances and control their switching. A 30A relay is also used for the control of heavy loads such as air conditioners, refrigerators, heaters etc. Android mobile phones are used to control the system as they are the most popular ones in the market, also it has an open source operating system. Therefore, it can be used free of cost on mobile phones. The App has provisions for supporting Wi Fi network by allowing the device to exchange data with other devices wirelessly using Router. For voice control of light loads Google Assistant is used. Initially Applets are created for switching on and switching off of the relay on the forum IFTTT (If this then that). With the relay board using jumper wires. The code is uploaded to the NodeMCU. Authentic token is added in the code as well as the name of the Wi-Fi hotspot which is used. Then the password of the Wi-Fi hotspot is added to access the hotspot. Now the NodeMCU is connected to the Wi-Fi. For hardware assembly the NodeMCU is connected appropriate request to the App which in turn sends the request to the NodeMCU board and controls the relay.

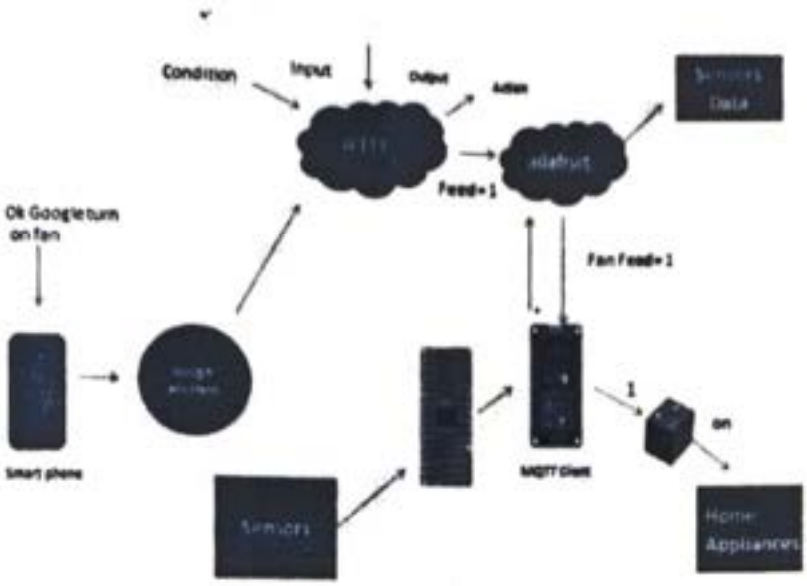

Fig 3.2 System Architecture for Home Control System

3.2.3 FLOWCHART

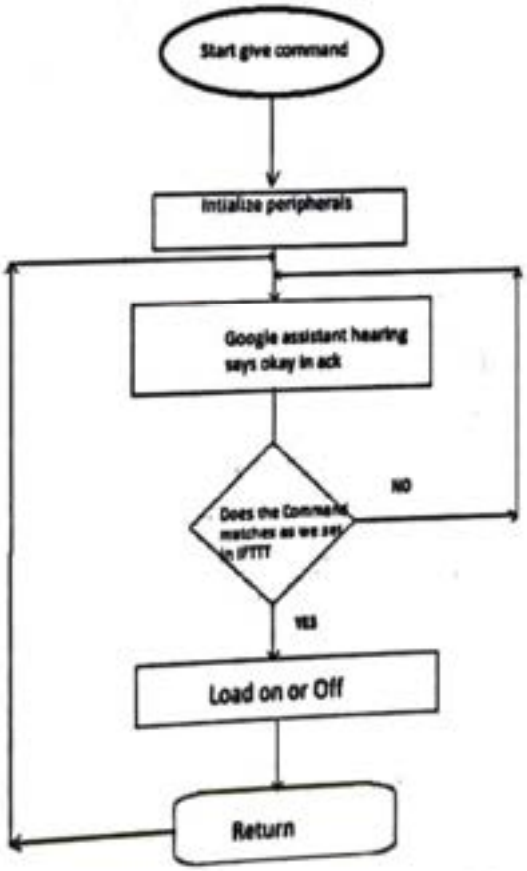

Fig 3.3 Flowchart for Home Control System

The Home control system which wok based on the user Commands

- First the User enter into the Google Assistant and Gives the command as Turn ON light.
- The Commands are send to the IFTTT interface where the commands are preprogrammed in IFTTT.
- Then IFTTT the user commands are triggered to Adafruit based on the commands given to Adafruit in IFTTT Applet.
- Then in Adafruit the created dashboard and feed is activated and turned ON and send to the Microcontroller (esp8266) through WI-FI.
- Finally, the Light is turned on.

CHAPTER 4
SYSTEM SPECIFICATION

4.1 HARDWARE REQUIREMENTS:

System : Pentium IV 2.4 GHz.
Hard Disk : 250 GB.
Monitor : 15 VGA Colour.
Mouse : Optical.
Ram : 1 GB.
Mobile : Android.

4.2 SOFTWARE REQUIREMENTS:

Operating System : Windows 7/8/10.
IDE : Arduino.
Platform : Adafruit, IFTTT.
Speech Interface : Google Assistant.

4.3 SOFTWARE ENVIRONMENT

4.3.1 ARDUINO IDE

A minimal Arduino C/C++ sketch, as seen by the Arduino IDE programmer, consist of only two functions.

- Setup (): This function is called once when a sketch starts after power-up or reset. It is used to initialize variables, input and output pin modes, and other libraries needed in the sketch.
- Loop (): After setup () has been called, function loop () is executed repeatedly in the main program. It controls the board until the board is powered off or is reset.

Most Arduino boards contain a light-emitting diode (LED) and a load resistor connected between pin 13 and ground, which is a convenient feature for many tests and program functions. A typical program for a beginning Arduino programmer blinks a LED repeatedly. This program uses the functions pin Mode (), digital Write (), and delay (), which are provided by the internal libraries included in the IDE environment. The program is usually loaded in the Arduino by the manufacturer. Arduino IDE and C language allow the programming of the low level registers in the atmega328P.

Instructions like DDRB=0b00000001 for changing PORTB input/output pins are allowed. Fig 4.1 shows the basic program of Arduino IDE.

Fig 4.1 Arduino IDE

4.3.2 Adafruit

Adafruit Industries is an open-source hardware company based in New York City. It was founded by Limor Fried in 2005. The company designs, manufactures and sells a number of electronics products, electronics components, tools and accessories. It also produces a number of learning resources, including live and recorded videos related to electronics, technology, and programming. MQTT, or message queue telemetry transport, is a protocol for device communication that Adafruit IO supports. Using a MQTT library or client can publish and subscribe to a feed to send and receive feed data.

Fig 4.2 Adafruit Feeds

Integrating IoT features into projects is all fine and good, but this is usually only half the work! The other half involves processing the data and getting some kind of user input.

Blocks

The Adafruit IO dashboard works with units called blocks that can be used to either display IoT information or obtain user input. The dashboard can also be accessed using common web browsers, which allows for just about any device to use the dashboard. This is really helpful in situations where developing a specific app for a mobile or tablet would be either too difficult or take too long to complete. Luckily, browser-based programs are cross-platform.

Toggle

The toggle block allows to add a toggle button to dashboard that can be used to set the value of a feed. This can be helpful when creating IoT devices such as smart lights, doors, curtains, toasters, and even windows. These devices can be turned on and off using the toggle switch.

Fig 4.3 Toggle Button

4.3.3 IFTTT

IFTTT derives its name from the programming conditional statement if this, then that. IFTTT is both a website and a mobile app that launched in 2010 and has the slogan "Put the Internet to work for". The idea is the use IFTTT to automate everything from user favourite apps and websites to app - enabled accessories and smart devices. What the company provides is a software platform that connects apps, devices and services from different developers in order to trigger one or more automations involving those apps, devices and services. Here, IFTTT application is used to bridge the gap between the Google Assistant commands and the Smart phone. Setting up the IFTTT application first requires logging in after which user need to create an applet and then the trigger, 16 here is select Google Assistant and then type in the commands to which the Google Assistant should respond and to this command it should control the appliance/relay associated with it. The response

command from the Goggle Assistant can also be typed in as desired. After configuring the trigger, the application user need to configure. What should be done once the Google Assistant hears the command just configured? This is decided by setting that of the app. communication is done via the internet and since the microcontroller, NodeMCU comes with inbuilt WI - FI module, it is programmed to connect to the desired network once plugged in. C language is used to program the microcontroller and is programmed in the Arduino IDE

Fig 4.4 IFTTT

IFTTT is both a website and a mobile app. The free service launched in 2010 with the following slogan: "Put the Internet to work for". It's changed a lot in recent years, however. Currently, with IFTTT, user can connect all the "services" together so that tasks are automatically completed. There are numerous ways user can connect all services and the resulting combinations are called "Applets".

Applets essentially automate user daily workflow, whether it's managing smart home devices or apps and websites. So, for instance, the Philips Hue smart lighting system, user could use IFTTT to automatically turn on a light every time tagged in a Facebook photo. In another example, user could use IFTTT to automatically email readers when they comment on Word Press blog.

Services

IFTTT currently supports more than 360 services. User will find integrations for everything from iRobot vacuums to Facebook.

Applets

Applets are specific things that can happen when connect services. For instance, by use an Applet to sync Amazon Alexa to-dos with Google Calendar, or use one that lets create events in

iPhone Calendar via Google Assistant. There are tonnes of Applets to choose from IFTTT says there are 11 million users running more than a billion Applets a month.

Steps involved in IFTTT Applet Creation:

1. Login to IFTTT's website.
2. Create New Applet.
3. Select the + This in the "If This Then That" logo toward the centre-top of the page. This will allow user to look for the "trigger" that will tell the Applet when to run.
4. User can then search for and select a service. In this example, user use Google Assistant. User need to connect to it and authorize access to Google account.
5. User will then see a choice of triggers. Pick one. In this example, "Turn On light". This command is given to Google Assistant by the user.
6. Now, user need to select the + That in the "If This Then That" logo toward the centre-top of the page. This is where user will specify what to happen next.
7. Choose an action service. For instance, select the Adafruit. This will trigger the Light Feed to ON in the Adafruit.
8. Review Applet and click Finish when done.
9. It will now be live. To view the Applet, select My Applets from the top of IFTTT dashboard.

CHAPTER 5
PROJECT DESCRIPTION

5.1 PROBLEM STATEMENT

The IoT is used in order to control the home appliances where the home appliances are remotely controlled using a web page buttons, where user have to go to the particular link and from there user can press buttons in order to control the home appliance. By using this system user can be accessed Home devices or appliances anywhere from the world with the help of internet.

5.1.1 OVERVIEW OF THE PROJECT

The place where one fancies or desires to be after a long tiring day. People come home exhausted after a long hard working day. Some are way too tired that they find it hard to move once they land on their couch, sofa or bed. So any small device/technology that would help them switch theirs lights on or off, or play their favourite music etc. on a go with their voice with the aid of their smart phones would make their home more comfortable. Moreover, it would be better if everything such as warming bath water and adjusting the room temperature were already done before they reach their home just by giving a voice command. So, when people would arrive home, they would find the room temperature, the bath water adjusted to their suitable preferences, and they could relax right away and feel costlier and rather, feel homelier.

Human assistants like housekeepers were a way for millionaires to keep up their homes in the past. Even now when technology is handy enough only the well to do people of the society are blessed with these new smart home devices, as these devices costs are a bit high. However, not everyone is wealthy enough to be able to afford a human assistant, or some smart home kit. Hence, the need for finding an inexpensive and smart assistant for normal families keeps growing. This proposes such inexpensive system. It uses the Google Assistant, the IFTTT application, the Adafruit and the Node MCU microcontroller as the major components along with a relay board comprising of 4/8 relays along with ULN 2803 IC. Natural language voice is used to give commands to the Google Assistant. All of the components are connected over the internet using Wi-Fi which puts this system under the IoT.

An important usability goal when the user sends command through Google assistant it first goes to the IFTTT there we given set statements that states he IF THIS THEN THAT user can understand this system. From there it goes to the adafruit is cloud service it is like MQTT broker which interacts with the Node MCU The Control Unit comprises of the microcontroller- Node MCU

and the 4 Channel Relay board. Android device communicates with the microcontroller and sends the desired signal via the internet.

5.2 MODULE DESCRIPTION

5.2.1 NodeMCU (esp8266)

The NodeMCU (Node Microcontroller Unit) is an open source software and hardware development environment that is built around a very inexpensive System-on-a-Chip (SoC) called the ESP8266. The ESP8266 is designed and manufactured by Express, contains all crucial elements of the modern computer: CPU, RAM, networking (Wi-Fi), and even a modern operating system and SDK. When purchased at bulk, the ESP8266 chip costs only $2 USD a piece. That makes it an excellent choice for this system design. The NodeMCU aims to simplify ESP8266 development. It has two key components.

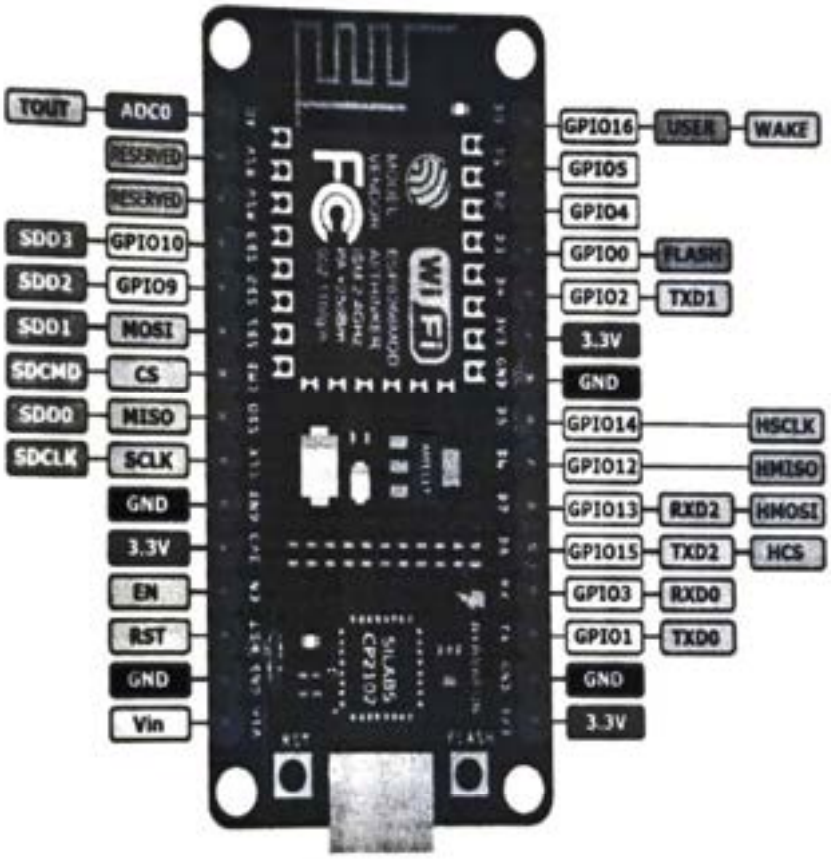

Fig 5.1 Node MCU

i. An open source ESP8266 firmware that is built on top of the chip manufacturer's Proprietary SDK. The firmware provides a simple programming environment based on eLua (embedded Lua), which is a very simple and fast scripting language with an established developer community. For new comers, the Lua scripting language is easy to learn. And to add on NodeMCU can be programmed with the Android IDE too.

ii. A development kit board that incorporates the ESP8266 chip on a standard circuit board. The board has a built-in USB port that is already wired up with the chip, a hardware reset button, Wi-Fi antenna, LED lights, and standard-sized GPIO (General Purpose Input Output) pins that can plug into a bread board.

5.2.2 RELAY BOARD

A relay is an electromagnetic switch. It is activated when a small current of some microampere is applied to it. Normally a relay is used in a circuit as a type of switch, an automatic switch. There are different types of relays and they operate at different voltages. When a circuit is built the voltage that will trigger it has to be considered. In this system the relay circuit is used to turn the appliances ON/OFF. The high/low signal is supplied from the NodeMCU microcontroller. When a low voltage is given to the relay of an appliance it is turned off and when a high voltage is given it is turned on. The relay circuit to drive four appliances in the Home automation. The number of appliances can be modified according to the user's requirements

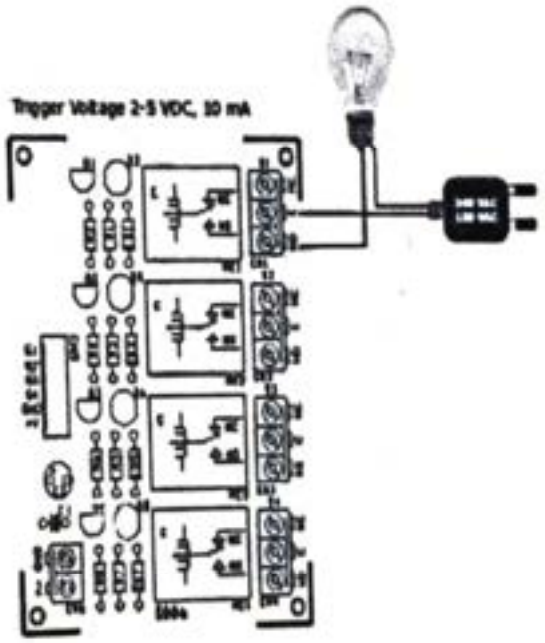

Fig 5.2 Relay module

CHAPTER 6

CONCLUSION AND FUTURE ENHANCEMENT

6.1 CONCLUSION

The aim is to propose a cost effective voice controlled (Google Assistant) home automation controlling general appliances found in one's home. The approach discussed was successful as GACHA's (Google Assistant Controlled Home Automation) design was successfully implemented. This system is highly reliable and efficient for the aged people and differently abled person on a wheel chair who cannot reach the switch for the switching ON/OFF the device and are dependent on others and also it provides centralized control of many equipment such as lights, blinds, Television, Air conditioners, security and surveillance system, kitchen appliances etc. This system can be expanded to control a large number of appliances and effectively cover not only the bedroom and kitchen but the entire house. The voice control using IFTT also facilitates control of appliances over the web. Hence the constraint of proximity concerned with Google Assistant.

6.2 FUTURE ENHANCEMENT

There are a variety of enhancements that could be made to this system to achieve Greater accuracy in sensing and detection.

a) There are a lot of other sensors that can be used to increase the security and control of the home like pressure sensor that can be put outside the home to detect that someone will enter the home.

b) Changing the way of the automated notifications by using the GSM module to make this system more professional.

c) A smart garage that can measure the length of the car and choose which block to put the car into it and it will navigate the car through the garage to make the parking easy for the homeowner in his garage.

The future scope for GACHA can be huge. There are many factors to improve on to make GACHA more powerful, intelligent, scalable, and to become better overall for home automation. For example, controlling the speed of the fan, more number of devices can be integrated, like a coffee machine, air conditioner etc. To make the system respond faster by use of Google Assistant can be made. Well, no system is ever perfect. It always has a scope for improvement. One just needs to put on a thinking cap and try and make the system better.

APPENDIX

CODING

```
#define LED1 D0
#define LED2 D2
AdafruitIO_Feed *led1 = io.feed("led1");
AdafruitIO_Feed *led2 = io.feed("led2");
void setup()

ABSTRACT

A proposal for home control using voice via Google Assistant. There are home automation technologies introduced over these years from ZigBee automation, Amazon Echo, Google home etc., It describes the implementation of such a system. The system is implemented using ordinary household appliances Natural language voice commands are given to the Google Assistant and with the help of IFTTT (If This Then That) application and the Adafruit the commands are decoded and then sent to the microcontroller, the microcontroller in turn controls the relays connected to it as required, turning the device connected to the respective relay On or OFF as per the users request to the Google Assistant. The microcontroller used is NodeMCU (ESP8266) and the communication between the microcontroller and the application is established via Wi-Fi (Internet).

CHAPTER 1
INTRODUCTION

1.1 OVERVIEW

Home, it is the place where one fancies or desires to be after a long tiring day. People come home exhausted after a long hard working day. Some are way too tired that they find it hard to move once they land on their couch, sofa or bed. So any small device/technology that would help them switch theirs lights on or off, or play their favourite music etc. on a go with their voice with the aid of their smart phones would make their home more comfortable.

Moreover, it would be better if everything such as warming bath water and adjusting the room temperature were already done before they reach their home just by giving a voice command. So, when people would arrive home, they would find the room temperature, the bath water adjusted to their suitable preferences, and they could relax right away and feel cosier and rather, feel homelier. Human assistants like housekeepers were a way for millionaires to keep up their homes in the past. Even now when technology is handy enough only the well to do people of the society are blessed with these new smart home devices, as these devices costs are a bit high. However, not everyone is wealthy enough to be able to afford a human assistant, or some smart home kit. Hence, the need for finding an inexpensive and smart assistant for normal families keeps growing. It uses the Google Assistant, the IFTTT Web interface, the Adafruit Web Interface and the NodeMCU microcontroller as the major components along with a relay board comprising of 4/8 relays along with ULN 2803 IC. Natural language voice is used to give commands to the Google Assistant. All of the components are connected over the internet using Wi-Fi which puts this system under the IoT.

1.2 OBJECTIVES

The aim is to provide a cheap home automation system to assist common man's life to make his schedule more efficient and help conserve energy; it will also be of great use to handicapped and elderly members of our society.

The system has two modules in totality; the first module consists of control of lights, blinds and fans which will be switched on and off using voice commands on Google assistant. The second module consists of control of common household appliances such as television, projector, air conditioners etc. Intend to attach four loads in this work and the control of the appliances will be done using two methods in particular; they are App and voice control. Voice control can easily be achieved on an Android mobile using Google Assistant.

1.3 PROBLEM STATEMENTS

The main problems that a home automation system faces are high cost of the system, strenuous configuration and set up process and security of the system. This developed system will be much cheaper than the available systems in the market and cover the control of most of the commonly used home appliances in a house using an Android App and voice control using Google Assistant on the user's mobile. The system is wireless and will be using Bluetooth as well as Wi-Fi to allow the user to control various appliances using their mobile phones, personal computers/ Laptops etc. It has never been easier or more affordable to purchase and install smart devices and home control systems. The drawback, however, is that systems are regularly being installed incrementally without a central control point. And that can lead to home automation problems.

CHAPTER 2
LITERATURE SURVEY

2.1 Smart Home Using Wi-Fi

NiharikaShrotriya et al., [1] proposed the system allows the people think about home automation, most of them may imagine living in a smart home: One remote controller for every household appliance, cooking the rice automatically, starting air conditioner automatically, heating water for bath automatically and shading the window automatically during night. To some extent home automation equals to smart home. They both bring out smart living condition and make our life more convenient and fast. Early home automation began with labour-saving machines. Self-contained electric or gas powered home appliance became viable in the 1900s with the introduction of electric power distribution led to the introduction of washing machine (1904), water heater (1889), refrigerator, sewing machines, dishwashers and clothes dryers. As per the survey currently there exists system neither at cheaper rates nor easy to handle. Various systems are hard to install, difficult to use and maintain.

2.2 Development of Internet Based System:

Tan, et al., [2] proposed the development of an Internet-based system to allow monitoring of important process variables from a distributed control system (DCS). The hardware and software design considerations which enable the user to access the process variables on the DCS, remotely and effectively rent designations.

The use of speech to interact remotely with the home appliances to perform a particular action on behalf of the user. The approach is inclined for people with disability to perform real-life operations at home by directing appliances through speech. Voice separation strategy is selected to take appropriate decision by speech recognition. It is one of the difficult system to process it.

2.3 A System for Smart-Home Control of Appliances Based on Time and Speech Interaction:

S. M. AnamulHaque et al., [3] proposed a system entitled "A System for Smart-Home Control of Appliances Based on Time and Speech Interaction" that controls the home appliances using the personal computer. The system is developed by using the Visual Basic 6.0 as programming language and Microsoft voice engine tools for speech recognition purpose. Appliances can be either controlled by timer or by voice command. The remote monitoring through mobile phone involving the use of spoken commands. The spoken commands are generated and sent in the form of text SMS to the control system and then the microcontroller on the basis of SMS and it takes the difficult for decision a particular task.

2.4 Home Automation and Security using Android ADK:

DeepaliJavale et al., [4], proposed the design of home automation and security system using android ADK. The design is based on Standalone embedded system board android ADK (Accessory Development Kit) at home. Home appliances are connected to the ADK and communication is established between the ADK and android mobile device or tablet. The home appliances are connected to the input/output ports of embedded system board and their status is passed to ADK. They have developed an authentication to the system for authorized person to access home appliances. The device with high cost and scalable to less modification to the core is used. It presents the design and implementation of automation system that can monitor and control home appliances via android phone or tablet.

2.5 Safe and Secure PIC Based Remote Control Application for Intelligent Home:

E. Yavuz et al., [5] proposed the secure PIC based remote control system for intelligent houses has been presented. With this implemented system, it is possible to safely control electricity operated domestic devices by the help of public or mobile phones from any places all over the world. Developed remote control device has been optically and electrically isolated to secure the system.

2.6 Bluetooth Based Home Automation System:

N. Sriskanthan et al., [6] proposed the Journal of Microprocessors and Microsystems, the "Home Automation" concept has existed for many years. The terms "Smart Home", "Intelligent Home" followed and has been used to introduce the concept of networking appliances and devices in the house. Home automation Systems (HASs) represents a great research opportunity in creating new fields in engineering, architecture and computing (Huidobro and Millan, 2004). HASs becoming popular nowadays and enter quickly in this emerging market. However, end users, especially the disabled and old aged due to their complexity and cost, do not always accept these systems. Due to the advancement of wireless technology, there are several different of connections are introduced such as GSM, WIFI, ZIGBEE, and Bluetooth. Each of the connection has their own unique specifications and applications. Among the four popular wireless connections that often implemented in HAS project, Bluetooth is being chosen with its suitable capability. Bluetooth with globally available frequencies of 2400Hz is able to provide connectivity up to 100 meters at speed of up to 3Mbps depending on the Bluetooth device class.

2.7 Home Automation Using Internet of Things:

Kusuma [7] proposed a Home Automation system that employs the integration of multi-touch mobile devices, cloud networking, wireless communication, and power-line communication to provide the user with remote control of various lights and appliances within their home. This system uses a consolidation of a mobile phone application, handheld wireless remote, and PC based program to provide a means of user interface to the consumer.

The main objective is to design and implement a control and monitor system for smart house. Smart house system consists of many systems that controlled by LAB VIEW software as the main controlling system. Also, the smart house system was supported by remote control system as a sub controlling system. The system also is connected to the internet to monitor and control the house equipment's from anywhere in the world using LAB VIEW.

Deepali Javale [4], also proposed the prime objective is to assist handicapped/old aged people. It gives basic idea of how to control various home appliances and provide a security using Android phone/tab. The design consists of Android phone with home automation application, Arduino Mega ADK. User can interact with the android phone and send control signal to the Arduino ADK which in turn will control other embedded devices/sensors.

A new design for the smart home using the wireless sensor network and the biometric technologies. The system employs the biometric in the authentication for home entrance which

2.6 Bluetooth Based Home Automation System:

N. Sriskanthan et al., [6] proposed the Journal of Microprocessors and Microsystems, the "Home Automation" concept has existed for many years. The terms "Smart Home", "Intelligent Home" followed and has been used to introduce the concept of networking appliances and devices in the house. Home automation Systems (HASs) represents a great research opportunity in creating new fields in engineering, architecture and computing (Huidobro and Millan, 2004). HASs becoming popular nowadays and enter quickly in this emerging market. However, end users, especially the disabled and old aged due to their complexity and cost, do not always accept these systems. Due to the advancement of wireless technology, there are several different of connections are introduced such as GSM, WIFI, ZIGBEE, and Bluetooth. Each of the connection has their own unique specifications and applications. Among the four popular wireless connections that often implemented in HAS project, Bluetooth is being chosen with its suitable capability. Bluetooth with globally available frequencies of 2400Hz is able to provide connectivity up to 100 meters at speed of up to 3Mbps depending on the Bluetooth device class.

2.7 Home Automation Using Internet of Things:

Kusuma [7] proposed a Home Automation system that employs the integration of multi-touch mobile devices, cloud networking, wireless communication, and power-line communication to provide the user with remote control of various lights and appliances within their home. This system uses a consolidation of a mobile phone application, handheld wireless remote, and PC based program to provide a means of user interface to the consumer.

The main objective is to design and implement a control and monitor system for smart house. Smart house system consists of many systems that controlled by LAB VIEW software as the main controlling system. Also, the smart house system was supported by remote control system as a sub controlling system. The system also is connected to the internet to monitor and control the house equipment's from anywhere in the world using LAB VIEW.

Deepali Javale [4], also proposed the prime objective is to assist handicapped/old aged people. It gives basic idea of how to control various home appliances and provide a security using Android phone/tab. The design consists of Android phone with home automation application, Arduino Mega ADK. User can interact with the android phone and send control signal to the Arduino ADK which in turn will control other embedded devices/sensors.

A new design for the smart home using the wireless sensor network and the biometric technologies. The system employs the biometric in the authentication for home entrance which

enhances home security as well as easiness of home entering process. The structure of the system is described and the incorporated communications are analyzed, also an estimation for the whole system cost is given which is something lacking in a lot of other smart home designs offers. WB-SH is designed to be capable of incorporating in a building automation system and it can be applied to offices, clinics, and other places. It ends with an imagination for the future of the smart home when employs the biometric technology in a larger and more comprehensive form. It ends with an imagination for the future of the smart home when employs the biometric technology in a larger and more comprehensive form.

CONCLUDING REMARKS:

The various literature survey has published here which the systems are hard to install, difficult to maintain. The proposed system were not in optimized and user friendly.

Our Proposed system is easily accessible from mobile itself and provides access anywhere from the world and there is no need of any separate interface to run it. Current systems are generally proprietary, closed and user friendly. Based on Arduino and low cost home automation system.

CHAPTER 3

SYSTEM ANALYSIS

3.1 EXISTING SYSTEM

The IoT is used in order to control the home appliances where the home appliances are remotely controlled using a web page buttons, where the user have to go to the particular link and from there to press buttons in order to control the home appliance. It involves the control the lighting, heating, ventilation, air conditioning and security, as well as home appliances. Remote or sensors are used for controlling Home devices, Modern systems generally consists of switches and sensors connected to a central hub called a gateway from which the system is controlled with a user interface that is interacted either with a mobile phone software ,tablet, computers or a web interface often but not always via internet cloud services.

To some extent home automation equals to smart home. They both bring out smart living condition and make our life more convenient and fast. Early home automation began with labour-saving machines. Self-contained electric or gas powered home appliance became viable in the 1900s with the introduction of electric power distribution led to the introduction of washing machine water heater refrigerator, sewing machines, dishwashers and clothes dryers. As per the survey currently there exists system neither at cheaper rates nor easy to handle. Various systems are hard to install, difficult to use and maintain. Current systems are generally proprietary, closed and not very user friendly Based on Arduino or GSM or low cost home security system and home automation system.

3.1.1 DISADVANTAGE OF EXISTING SYSTEM

- The operating is difficult.
- A separate web page is required.
- For every switching on and off user want to login into web page.

3.2 PROPOSED SYSTEM

The idea is to integrate the concept of Google Assistant into Arduino and control the appliances in the home that the device is installed. Google recently released an API for Google Assistant, for platforms other than Android, such as Linux and Windows, using Python language.

When the user sends command through Google assistant it first goes to the IFTTT there the given set statements that states he IF THIS THEN THAT can understand this when the architecture

of our system. From there it goes to the Adafruit is cloud service it is like MQTT broker which interacts with the NodeMCU. The Control Unit comprises of the microcontroller- Node MCU and the 4 Channel Relay board. Android device communicates with the microcontroller and sends the desired signal via the internet.

The system has the capabilities to control the following components in user's home and monitor the following alarms: Temperature and humidity Motion Detection Light level and Lights on/off dim Fan on/off On/off different appliance and also Provide a more user-friendly interaction Various issue are solved like sending notification by providing the data monitoring system so it can be control the sensors data. Very simple and provide interaction with Google assistant.

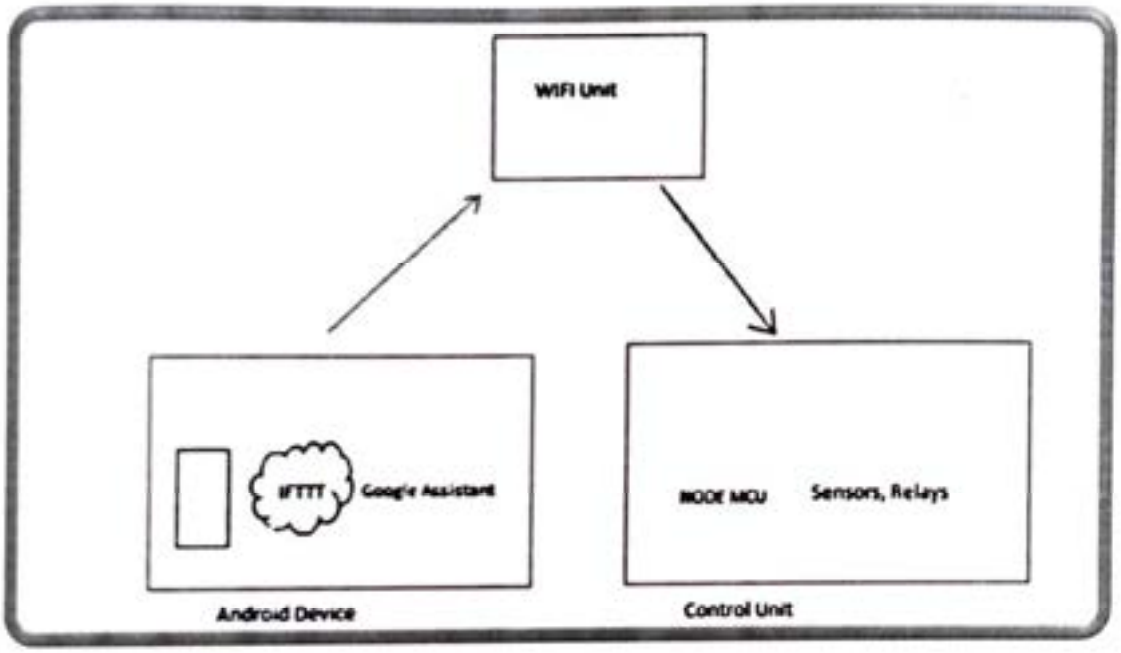

Fig 3.1 Overall Design

The system which has WI-FI as the control unit. It enhances the data from Microcontroller to web interfaces and also from web interfaces to microcontroller. The IFTTT and Google Assistant are used as an android devices and NodeMCU, Sensors, Relay are used as the control unit in the Home control system.

Voice controlled home automation is a step further in easing the control of appliances. This helps the handicapped as well as elderly people to access the home appliances with ease. As technology grows and expands with every single moment, automations have also taken leaps and bounds. Earlier a niche field which was accessible to only a select few, Home Automation is now becoming economically accessible to a much larger market. Through this system is intend to make

home automation economically accessible to every family. An automation system for home which makes use of cloud computing and wireless communication has been studied. This is found to be cheaper. The internet of things is intended to bring everything in the universe under a single framework. This provides greater control of the stuff while updating the user on the status of things. Communication was also made possible through Bluetooth to automate home appliances. New schemes for smarter homes were discussed and advancements were introduced. Home appliances can also be controlled by using RP along with the concept of relay circuit by adopting a web page.

3.2.1ADVANTAGES OF PROPOSED SYSTEM

- System can be easily accessible from mobile itself.
- It provides Access from anywhere the system is connected to server.
- The system no need of any interface for communication. Google assistance is enough.

3.2.2 SYSTEM ARCHITECTURE

The Home Automation system will have about two modules.

- The first module consists of control of lighting, fans etc. using an Android phone App as well as voice commands using Google Assistant.
- The second module consist of control of various heavy power Household appliances such as television, air conditioner, Iron box etc.

Different types of applications using android platform with Wi-Fi can be further developed. In this work a four channel 12V relay is used to connect the appliances and control their switching. A 30A relay is also used for the control of heavy loads such as air conditioners, refrigerators, heaters etc. Android mobile phones are used to control the system as they are the most popular ones in the market, also it has an open source operating system. Therefore, it can be used free of cost on mobile phones. The App has provisions for supporting Wi Fi network by allowing the device to exchange data with other devices wirelessly using Router. For voice control of light loads Google Assistant is used. Initially Applets are created for switching on and switching off of the relay on the forum IFTTT (If this then that). With the relay board using jumper wires. The code is uploaded to the NodeMCU. Authentic token is added in the code as well as the name of the Wi-Fi hotspot which is used. Then the password of the Wi-Fi hotspot is added to access the hotspot. Now the NodeMCU is connected to the Wi-Fi. For hardware assembly the NodeMCU is connected appropriate request to the App which in turn sends the request to the NodeMCU board and controls the relay.

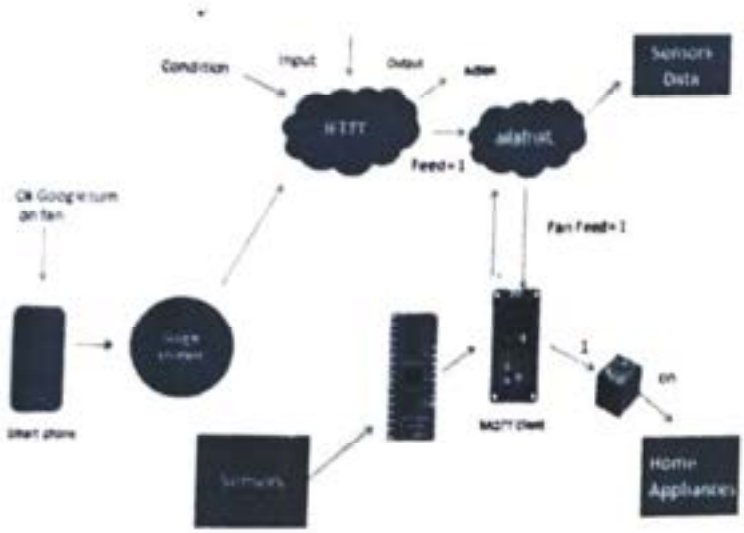

Fig 3.2 System Architecture for Home Control System

3.2.3 FLOWCHART

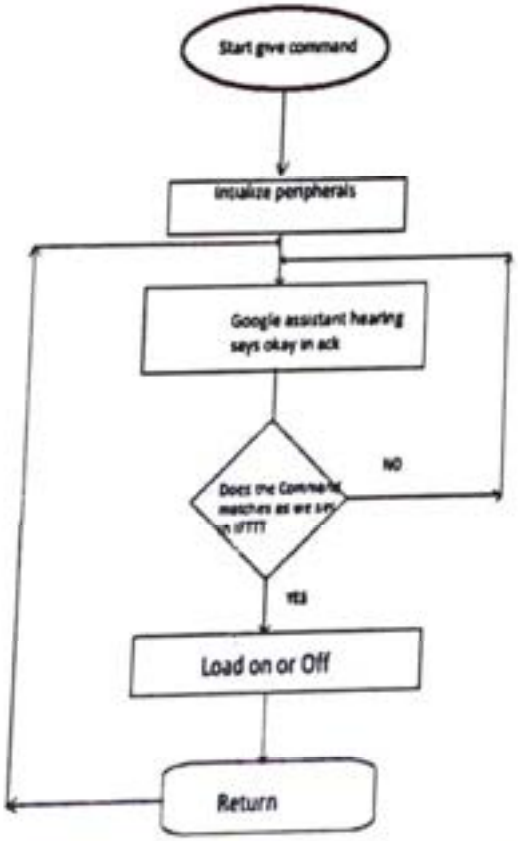

Fig 3.3 Flowchart for Home Control System

The Home control system which wok based on the user Commands

- First the User enter into the Google Assistant and Gives the command as Turn ON light.
- The Commands are send to the IFTTT interface where the commands are preprogrammed in IFTTT.
- Then IFTTT the user commands are triggered to Adafruit based on the commands given to Adafruit in IFTTT Applet.
- Then in Adafruit the created dashboard and feed is activated and turned ON and send to the Microcontroller (esp8266) through WI-FI.
- Finally, the Light is turned on.

CHAPTER 4

SYSTEM SPECIFICATION

4.1 HARDWARE REQUIREMENTS:

System : Pentium IV 2.4 GHz.

Hard Disk : 250 GB.

Monitor : 15 VGA Colour.

Mouse : Optical.

Ram : 1 GB.

Mobile : Android.

4.2 SOFTWARE REQUIREMENTS:

Operating System : Windows 7/8/10.

IDE : Arduino.

Platform : Adafruit, IFTTT.

Speech Interface : Google Assistant.

4.3 SOFTWARE ENVIRONMENT

4.3.1 ARDUINO IDE

A minimal Arduino C/C++ sketch, as seen by the Arduino IDE programmer, consist of only two functions.

• Setup (): This function is called once when a sketch starts after power-up or reset. It is used to initialize variables, input and output pin modes, and other libraries needed in the sketch.

• Loop (): After setup () has been called, function loop () is executed repeatedly in the main program. It controls the board until the board is powered off or is reset.

Most Arduino boards contain a light-emitting diode (LED) and a load resistor connected between pin 13 and ground, which is a convenient feature for many tests and program functions. A typical program for a beginning Arduino programmer blinks a LED repeatedly. This program uses the functions pin Mode (), digital Write (), and delay (), which are provided by the internal libraries included in the IDE environment. The program is usually loaded in the Arduino by the manufacturer. Arduino IDE and C language allow the programming of the low level registers in the atmega328P.

Instructions like DDRB=0b00000001 for changing PORTB input/output pins are allowed. Fig 4.1 shows the basic program of Arduino IDE.

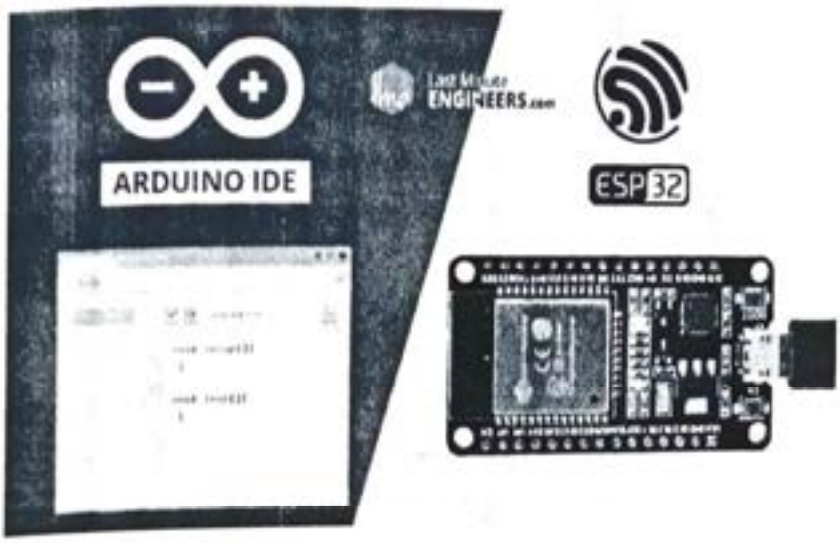

Fig 4.1 Arduino IDE

4.3.2 Adafruit

Adafruit Industries is an open-source hardware company based in New York City. It was founded by Limor Fried in 2005. The company designs, manufactures and sells a number of electronics products, electronics components, tools and accessories. It also produces a number of learning resources, including live and recorded videos related to electronics, technology, and programming. MQTT, or message queue telemetry transport, is a protocol for device communication that Adafruit IO supports. Using a MQTT library or client can publish and subscribe to a feed to send and receive feed data.

Fig 4.2 Adafruit Feeds

Integrating IoT features into projects is all fine and good, but this is usually only half the work! The other half involves processing the data and getting some kind of user input.

Blocks

The Adafruit IO dashboard works with units called blocks that can be used to either display IoT information or obtain user input. The dashboard can also be accessed using common web browsers, which allows for just about any device to use the dashboard. This is really helpful in situations where developing a specific app for a mobile or tablet would be either too difficult or take too long to complete. Luckily, browser-based programs are cross-platform.

Toggle

The toggle block allows to add a toggle button to dashboard that can be used to set the value of a feed. This can be helpful when creating IoT devices such as smart lights, doors, curtains, toasters, and even windows. These devices can be turned on and off using the toggle switch.

Fig 4.3 Toggle Button

4.3.3 IFTTT

IFTTT derives its name from the programming conditional statement if this, then that. IFTTT is both a website and a mobile app that launched in 2010 and has the slogan "Put the Internet to work for". The idea is the use IFTTT to automate everything from user favourite apps and websites to app - enabled accessories and smart devices. What the company provides is a software platform that connects apps, devices and services from different developers in order to trigger one or more automations involving those apps, devices and services. Here, IFTTT application is used to bridge the gap between the Google Assistant commands and the Smart phone. Setting up the IFTTT application first requires logging in after which user need to create an applet and then the trigger, 16 here is select Google Assistant and then type in the commands to which the Google Assistant should respond and to this command it should control the appliance/relay associated with it. The response

command from the Goggle Assistant can also be typed in as desired. After configuring the trigger, the application user need to configure. What should be done once the Google Assistant hears the command just configured? This is decided by setting that of the app. communication is done via the internet and since the microcontroller, NodeMCU comes with inbuilt WI - FI module, it is programmed to connect to the desired network once plugged in. C language is used to program the microcontroller and is programmed in the Arduino IDE

Fig 4.4 IFTTT

IFTTT is both a website and a mobile app. The free service launched in 2010 with the following slogan: "Put the Internet to work for". It's changed a lot in recent years, however. Currently, with IFTTT, user can connect all the "services" together so that tasks are automatically completed. There are numerous ways user can connect all services and the resulting combinations are called "Applets".

Applets essentially automate user daily workflow, whether it's managing smart home devices or apps and websites. So, for instance, the Philips Hue smart lighting system, user could use IFTTT to automatically turn on a light every time tagged in a Facebook photo. In another example, user could use IFTTT to automatically email readers when they comment on Word Press blog.

Services

IFTTT currently supports more than 360 services. User will find integrations for everything from iRobot vacuums to Facebook.

Applets

Applets are specific things that can happen when connect services. For instance, by use an Applet to sync Amazon Alexa to-dos with Google Calendar, or use one that lets create events in

iPhone Calendar via Google Assistant. There are tonnes of Applets to choose from IFTTT says there are 11 million users running more than a billion Applets a month.

Steps involved in IFTTT Applet Creation:

1. Login to IFTTT's website.
2. Create New Applet.
3. Select the + This in the "If This Then That" logo toward the centre-top of the page. This will allow user to look for the "trigger" that will tell the Applet when to run.
4. User can then search for and select a service. In this example, user use Google Assistant. User need to connect to it and authorize access to Google account.
5. User will then see a choice of triggers. Pick one. In this example, "Turn On light". This command is given to Google Assistant by the user.
6. Now, user need to select the + That in the "If This Then That" logo toward the centre-top of the page. This is where user will specify what to happen next.
7. Choose an action service. For instance, select the Adafruit. This will trigger the Light Feed to ON in the Adafruit.
8. Review Applet and click Finish when done.
9. It will now be live. To view the Applet, select My Applets from the top of IFTTT dashboard.

CHAPTER 5
PROJECT DESCRIPTION

5.1 PROBLEM STATEMENT

The IoT is used in order to control the home appliances where the home appliances are remotely controlled using a web page buttons, where user have to go to the particular link and from there user can press buttons in order to control the home appliance. By using this system user can be accessed Home devices or appliances anywhere from the world with the help of internet.

5.1.1 OVERVIEW OF THE PROJECT

The place where one fancies or desires to be after a long tiring day. People come home exhausted after a long hard working day. Some are way too tired that they find it hard to move once they land on their couch, sofa or bed. So any small device/technology that would help them switch theirs lights on or off, or play their favourite music etc. on a go with their voice with the aid of their smart phones would make their home more comfortable. Moreover, it would be better if everything such as warming bath water and adjusting the room temperature were already done before they reach their home just by giving a voice command. So, when people would arrive home, they would find the room temperature, the bath water adjusted to their suitable preferences, and they could relax right away and feel costlier and rather, feel homelier.

Human assistants like housekeepers were a way for millionaires to keep up their homes in the past. Even now when technology is handy enough only the well to do people of the society are blessed with these new smart home devices, as these devices costs are a bit high. However, not everyone is wealthy enough to be able to afford a human assistant, or some smart home kit. Hence, the need for finding an inexpensive and smart assistant for normal families keeps growing. This proposes such inexpensive system. It uses the Google Assistant, the IFTTT application, the Adafruit and the Node MCU microcontroller as the major components along with a relay board comprising of 4/8 relays along with ULN 2803 IC. Natural language voice is used to give commands to the Google Assistant. All of the components are connected over the internet using Wi-Fi which puts this system under the IoT.

An important usability goal when the user sends command through Google assistant it first goes to the IFTTT there we given set statements that states he IF THIS THEN THAT user can understand this system. From there it goes to the adafruit is cloud service it is like MQTT broker which interacts with the Node MCU The Control Unit comprises of the microcontroller- Node MCU

and the 4 Channel Relay board. Android device communicates with the microcontroller and sends the desired signal via the internet.

5.2 MODULE DESCRIPTION

5.2.1 NodeMCU (esp8266)

The NodeMCU (Node Microcontroller Unit) is an open source software and hardware development environment that is built around a very inexpensive System-on-a-Chip (SoC) called the ESP8266. The ESP8266 is designed and manufactured by Express, contains all crucial elements of the modern computer: CPU, RAM, networking (Wi-Fi), and even a modern operating system and SDK. When purchased at bulk, the ESP8266 chip costs only $2 USD a piece. That makes it an excellent choice for this system design. The NodeMCU aims to simplify ESP8266 development. It has two key components.

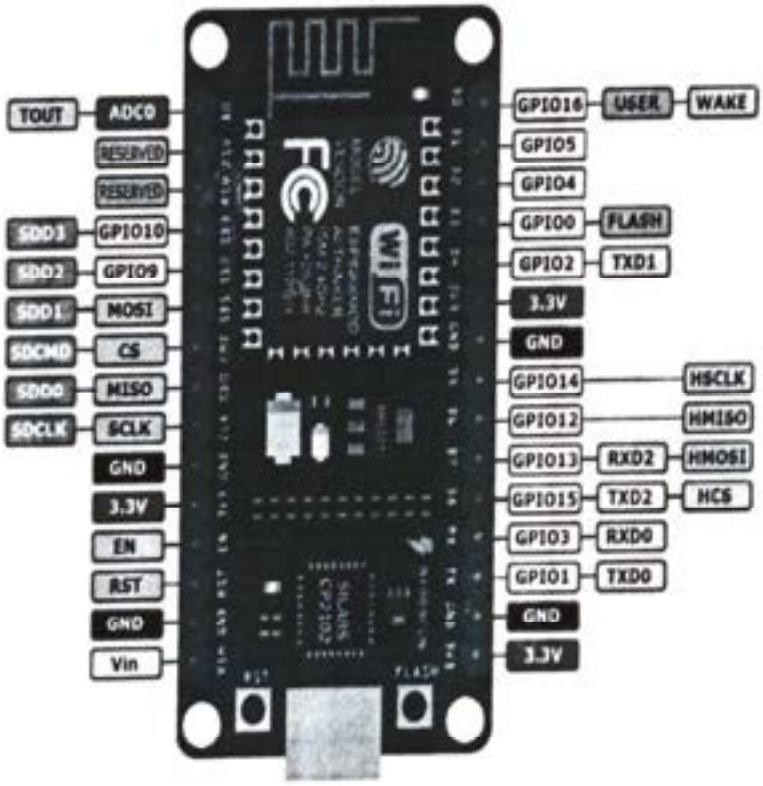

Fig 5.1 Node MCU

i. An open source ESP8266 firmware that is built on top of the chip manufacturer's Proprietary SDK. The firmware provides a simple programming environment based on eLua (embedded Lua), which is a very simple and fast scripting language with an established developer community. For new comers, the Lua scripting language is easy to learn. And to add on NodeMCU can be programmed with the Android IDE too.

ii. A development kit board that incorporates the ESP8266 chip on a standard circuit board. The board has a built-in USB port that is already wired up with the chip, a hardware reset button, Wi-Fi antenna, LED lights, and standard-sized GPIO (General Purpose Input Output) pins that can plug into a bread board.

5.2.2 RELAY BOARD

A relay is an electromagnetic switch. It is activated when a small current of some microampere is applied to it. Normally a relay is used in a circuit as a type of switch, an automatic switch. There are different types of relays and they operate at different voltages. When a circuit is built the voltage that will trigger it has to be considered. In this system the relay circuit is used to turn the appliances ON/OFF. The high/low signal is supplied from the NodeMCU microcontroller. When a low voltage is given to the relay of an appliance it is turned off and when a high voltage is given it is turned on. The relay circuit to drive four appliances in the Home automation. The number of appliances can be modified according to the user's requirements

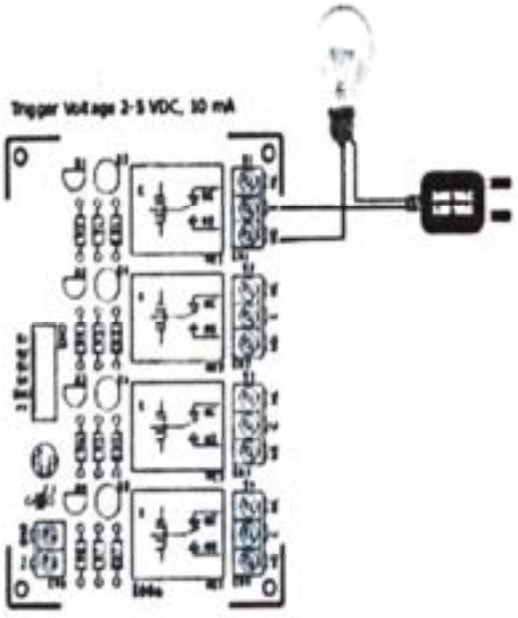

Fig 5.2 Relay module

CHAPTER 6

CONCLUSION AND FUTURE ENHANCEMENT

6.1 CONCLUSION

The aim is to propose a cost effective voice controlled (Google Assistant) home automation controlling general appliances found in one's home. The approach discussed was successful as GACHA's (Google Assistant Controlled Home Automation) design was successfully implemented. This system is highly reliable and efficient for the aged people and differently abled person on a wheel chair who cannot reach the switch for the switching ON/OFF the device and are dependent on others and also it provides centralized control of many equipment such as lights, blinds, Television, Air conditioners, security and surveillance system, kitchen appliances etc. This system can be expanded to control a large number of appliances and effectively cover not only the bedroom and kitchen but the entire house. The voice control using IFTT also facilitates control of appliances over the web. Hence the constraint of proximity concerned with Google Assistant.

6.2 FUTURE ENHANCEMENT

There are a variety of enhancements that could be made to this system to achieve Greater accuracy in sensing and detection.

a) There are a lot of other sensors that can be used to increase the security and control of the home like pressure sensor that can be put outside the home to detect that someone will enter the home.

b) Changing the way of the automated notifications by using the GSM module to make this system more professional.

c) A smart garage that can measure the length of the car and choose which block to put the car into it and it will navigate the car through the garage to make the parking easy for the homeowner in his garage.

The future scope for GACHA can be huge. There are many factors to improve on to make GACHA more powerful, intelligent, scalable, and to become better overall for home automation. For example, controlling the speed of the fan, more number of devices can be integrated, like a coffee machine, air conditioner etc. To make the system respond faster by use of Google Assistant can be made. Well, no system is ever perfect. It always has a scope for improvement. One just needs to put on a thinking cap and try and make the system better.

ABSTRACT

There is a growing demand for the software systems to recognize characters in computer systems when information is scanned through paper documents as it is known, that there are number of newspapers and books which are in printed format related to different subjects. In these days, there is a huge demand in storing the information available in these paper documents in to a computer's storage disk and then later reusing this information by searching process. One simple way to store information from these paper documents in to computer system is to first scan the documents and then store them as images. But to reuse this information it is very difficult to read the individual content and searching the contents form these documents line-by-line and word-by-word. The reason for this difficulty is the font characteristics of the characters in paper documents are different than the font of the characters in computer system. Optical Character Recognition (OCR) system based on a grid infrastructure to perform Document Image Analysis, document processing of electronic document formats converted from paper formats more effectively and efficiently is proposed.

CHAPTER 1

INTRODUCTION

1.1 Overview

The advancements in pattern recognition has accelerated recently due to the many emerging applications which are not only challenging, bu. also computationally more demanding, such evident in Optical Character Recognition (OCI.), Document Classification, Computer Vision, Data Mining, Shape Recognition, and Biometric Authentication. The area of OCR is becoming an integral part of document scanners, and is used in many applications such as postal processing, script recognition, banking, security and language identification [1]. The research in this area has been ongoing for over half a century and the outcomes have been astounding with successful recognition rates for printed characters exceeding 99%, with significant improvements in performance for handwritten cursive character recognition where recognition rates have exceeded the 90% mark. Many organizations are depending on OCR systems to eliminate the human interactions for better performance and efficiency [2]. Optical Character Recognition also referred to as OCR is a system that provides a full alphanumeric recognition of printed or handwritten characters at electronic speed by simply scanning the document. Documents are scanned using a scanner and are given to the OCR systems which recognizes the characters in the scanned documents and converts them into ASCII data.

OCR a database is used at the back end for recognition .The document scanning step, a scanner is used to scan the handwritten or printed documents. The quality of the scanned document depends up on the scanner [3]. So, a scanner with high speed and color quality is desirable. The recognizing process includes several complex algorithms and previously loaded templates and dictionary which are crosschecked with the characters in the document and the corresponding machine editable ASCII characters.

CHAPTER 2

LITERATURE SURVEY

2.1 Handwritten Chinese Character Recognition Based On Chinese Character Prototype

Jiang Shan (2000)

This paper discusses three kinds of Chinese character representations in a computer and two traditional analytical methods of Chinese character structure. By applying fundamental principles of topology and geometry to Chinese character structure and their constrained relations, four catalogues which contain basic relations to Chinese character structures are defined and Chinese character prototypes are constructed. Finally, an experiment is given to show how to use the prototypes in recognizing handwritten Chinese characters.

2.2 Optical Character Recognition: An Illustrated Guide To The Frontier

Thomas a. Nartker(2003)

ISRI had to develop new methodology for conducting large-scale tests of commercial systems. A large sample of documents was digitized scanned at several spatial sampling rates and both gray-scale and quantization. The page images were manually zoned to demarcate columns of text. The next step was the creation of groundtruth, an accurate transcription of each test document, against which the OCR outputs could be compared. A systematic protocol was established to guide more than forty key-entry operators to cope with non-ASCII symbols, foreign words, mathematical notation, strange layouts, and illustrations.

Each document was keyed in twice, and the results compared and reconciled. Next, a master program running on a unix platform was crafted to control a dozen PC's which ran the OCR software of the participating vendors. Perhaps the greatest technical challenge was the development of the algorithms required to compare the stream of characters produced by each OCR program with the ground truth files.

Columns, lines and words of text are not segmented reliably by OCR systems, line and character counts could not be depended upon for error detection. Nor could the position of the characters on the page, which is subject to distortion during the digitization process and not provided by many of the commercial systems. The solution finally selected was based on string matching techniques that determined the minimum number and the location of additions, deletions and substitutions necessary to correct the OCR output to match the ground truth.

2.3 An English Language OCR

Muhammad Umair Naru (2010)

Growing technology and fast living, business card are very much in demand. Most of the cards have fixed font size and style. That's why the OCR required for such documents does not need to be so expensive (computational cost) and complex (Artificial Neural Network). This paper presents a simple, efficient, and less costly approach to construct OCR for cards reading or any document that has fix font size and style. As English is an international language and almost every card have English characters on them. To achieve efficiency and less computational cost, OCR in this paper uses database instead of ANN (Artificial Neural Network) to recognize English characters which makes this OCR very simple to manage. As this paper is about English character recognition, so author is naming this OCR as α-soft, pronounced as "alpha soft". We have developed a prototype for this system. Different experiments are conducted to show that 100% accuracy is possible in OCR.

2.4 Character Recognition in practice Today and Tomorrow

Udo Miletzki(1996)

Handwriting recognition has been one of the most interesting and challenging research areas in field of image processing and pattern recognition in the recent years. This paper describes the techniques for converting textual content from a paper document into machine readable form. The computer actually recognizes the characters in the document through a revolutionizing technique called Optical Character Recognition. Several techniques like OCR using correlation method and OCR using neural networks are reviewed in this paper.

2.5 Prototype Extraction and Adaptive OCR

Yihong XU(1999)

To maintain OCR accuracy with decreasing quality of page image composition, production, and digitization, it is essential to tune the system to each document. We propose a prototype extraction method for document-specific OCR systems. The method automatically generates training samples from unsegment text images and the corresponding transcripts. It is tolerant of transcription errors, so a transcript produced automatically by an imperfect Omni font OCR system can be used. The method is based on new algorithms for estimating character widths, character locations in a word, and match/nonmatching probabilities from unsegment text. An experimental word recognition system is designed and developed to combine prototype extraction algorithms and segmentation-free word recognition. The system can adapt itself to different page images and achieve high recognition accuracy on heavily degraded print,

CHAPTER 3
SYSTEM ANALYSIS

3.1 Existing System

Cam scanner is a popular android application used to scan and save a printed document. An OCR is an inbuilt facility integrated with the application but it does not produce accurate result.

Printed documents in to electronic documents for maintaining the security of their data was done. Hence the basic OCR system was invented to convert the data available on papers in to computer process able documents. So, that the documents can be editable and reusable. The existing system/the previous system of OCR on a grid infrastructure is just OCR without grid functionality. That is the existing system deals with the homogeneous character recognition or character recognition of single language.

3.2 Drawback of Existing System

The drawback in the early OCR systems is that they only have the capability to convert and recognize only the documents of English or a specific language only. That is, the older 4 OCR system is uni-lingual.

3.3 Proposed System

The proposed system is also similar cam scanner but we have integrated auto spell check and auto grammar correction functionalities are added. Hence 90% of accurate result will be produced.

3.4 Advantages

- Optical Character Recognition (OCR) is one of the most widely implemented types of data entry methods.
- OCR involves digitized scanning and recognition of written or printed text.
- Text is first photo scanned, analyzed, and is finally translated into character codes. This machine-encoded text can be easily searched and edited electronically.
- OCR has greatly improved the process of data entry. This software tool enables quick conversion of scanned documents to searchable text files.
- The need for the documents to be scanned is on a constant rise as it enables these documents to be viewed conveniently when required. The scanned documents can also be shared easily through the electronic medium.

CHAPTER 4

SYSTEM REQUIREMENTS

4.1 Hardware Requirements

- Intel Pentium Processor
- 2GB of RAM
- 250GB ROM (Hard Disk)

4.2 Software Requirements

- Python 3
- PyQt5 for GUI
- Computer Vision API

CHAPTER 5
PROJECT DESCRIPTION

5.1 PROBLEM STATEMENT

The problem here is for the software systems to recognize characters in computer systems when information is scanned through paper documents as we know that we have number of newspapers and books which are in printed format related to different subjects. Whenever the documents are scanned through the scanner, the documents are stored as images such as jpeg, gif etc., in the computer system. These images cannot be read or edited by the user. But to reuse this information it is very difficult to read the individual contents and search the contents from these documents line-by-line and word-by-word. In these days, there is a huge demand in storing the information available in these paper documents in to a computer storage disk and then later editing or reusing this information by searching process.

5.2 System Model

An Optical Character Recognition is a conversion of images of typed, handwritten or printed text into machine-encoded text. The project using Google Cloud Vision API (Application Program Interface) by integrating with python programming language. For GUI (Graphical User Interface) PyQt5 package is used. The main functionality of the project is to recognize various types of handwritten documents and translating into multiple languages.

5.2.1 PyQt :

PyQt is a Python binding of the cross-platform GUI toolkit Qt, implemented as a Python plug-in. PyQt supports Microsoft Windows as well as various flavors of UNIX, including Linux and MacOS. PyQt5 is version 5 which is used in design GUI. It is licensed under GNU General Public License and commercial license.

5.2.2 Google vision API

Google Cloud's Vision API offers powerful pre-trained machine learning models through REST and RPC APIs. Assign labels to images and quickly classify them into millions of predefined categories.

CHAPTER 6

MODULE DESCRIPTION

6.1 Document Processing Module

This Module is accessed by administrator whose role in this application is a librarian. This module perform certain activities such as scanning documents, Storing them as images, recognizing characters in images to transfer them into word format. During the recognition process, this module uses the OCR methodology in support of grid infrastructure data structure. This module supports the following activities,

- Scanning printed documents.
- Storing the documents as snapshots or images.
- Processing those image based documents.
- Converting the image based documents into e-documents.
- Recognizing the character in documents.
- Generating grid infrastructure data structure

6.2 System Training Module

This Module can be accessed by both the administrator and the end user. Before converting the printed document into editable and searchable documents, the first and the mandatory step is providing training to the system. Here training in the sense the font followed in this scanned document should be identified by the user. Then the user types all the characters that are required for recognition from the scanned documents as an image file. This image file should be provided as an input during the training process. The user then clicks the train button provided in the recognition module. Then the training gets completed.

This module supports:

- Training the system with the pre-defined fonts.
- Training the system with the new fonts that are not present in the system and that cannot be identified by the system.

6.3 Document Recognition Module

This module can be accessed by both the administrator and the end-user. Once the printed documents are converted into structured documents, any user can recognize the characters present in the document. That means the user can recognize the characters of any language he chooses which makes OCR more flexible. This flexibility is due to the adaptation of grid infrastructure. This is the module where the main functionality of OCR is tested. Under this module, there are two types of recognition. Thus handwritten document recognition recognizes the human handwriting. In scanned document recognition, the system is first trained with the font characters in the document in the training module itself.

Hence the document recognition module on a whole supports the following services:

- Converts the document into specific format.
- Recognizes the characters.
- Heterogeneous character Recognition

6.4 Document Editing Module

This module can be accessed by both the administrator and the end-user during document editing to implement the character recognition process. Once the scanned documents are stored, they reside in computer memory. This data resides in the form of an image that is just viewable in an image viewer. Hence, the document is first converted into a form such that it is editable. The desired form of the document may be MS-Word, Text as specified by the user.

The objective of this module is to let the user perform :

- Addition of specific content to the documents
- Deletion of certain content from documents

CHAPTER 7

TESTING

7.1 Unit Testing

Unit testing involves the design of test cases that validate that the internal program logic is functioning properly, and that program input produces valid outputs. All decision branches and internal code flow should be validated. It is the testing of individual software units of the application .it is done after the completion of an individual unit before integration. This is a structural testing, that relies on knowledge of its construction and is invasive. Unit tests perform basic tests at component level and test a specific business process, application, and/or system configuration. Unit tests ensure that each unique path of a business process performs accurately to the documented specifications and contains clearly defined inputs and expected results.

7.2 Integration Testing

Integration tests are designed to test integrated software components to determine if they actually run as one program. Testing is event driven and is more concerned with the basic outcome of screens or fields. Integration tests demonstrate that although the components were individually satisfaction, as shown by successfully unit testing, the combination of components is correct and consistent. Integration testing is specifically aimed at exposing the problems that arise from the combination of components.

7.3 ACCEPTANCE TESTING

User Acceptance Testing is a critical phase of any project and requires significant participation by the end user. It also ensures that the system meets the functional requirements. Test Results: All the test cases mentioned above passed successfully. No defects encountered.

CHAPTER 8
CONCLUSION

OCR can become a powerful tool for future data entry applications for the entrepreneurial designers and sufficient research and development dollars. The limited availability of funds in a capital-short environment could restrict the growth of this technology. But, given the proper impetus and encouragement, a lot of benefits can be provided by the OCR system. The automated entry of data by OCR is one of the most attractive, labor reducing 85 technology. The recognition of new font characters by the system is very easy and quick. The information of the documents more conveniently can reuse the edited information as and when required. The Grid infrastructure used in the implementation of Optical Character Recognition system can be efficiently used to speed up the translation of image based documents into structured documents that are currently easy to discover, search and process.

SPEED CONTROL OF PERMANENT MAGNET SYNCHRONOUS MOTOR FOR THE RATE CONTROL OF WEAPON (GUN)

A PROJECT PHASE-I REPORT

Submitted by

ABBARNA E (16105001)

in partial fulfillment for the award of the degreeof

BACHELOR OF ENGINEERING

IN

ELECTRONICS AND COMMUNICATION ENGINEERING

PAAVAI ENGINEERING COLLEGE, NAMAKKAL

(AUTONOMOUS)

OCTOBER 2019

ABSTRACT

The main objective of the project is to stabilize the gun against the disturbances and to position the gun precisely against the target as well as to control the rate of the gun. All ac electrical gun control system is composed of permanent magnetic synchronous machine driven control system and ball-screw by replacing the complicated electro hydraulic systems. At the same time, the variable-structure system sliding modes makes the gun control system to have higher performances using the only rate flexure gyroscope. Elevation axis model of a barrel stabilization system is constructed. The nonlinearities which are considered in the model are orifice flow characteristics, coulomb friction, hard-stop limits, kinematics of the system and unbalance on the barrel. A Simulink model for the servo valve, actuation system and barrel is constructed. Servo valve identification is made via the actual test data. Compressibility of the hydraulic fluid is taken into consideration while modeling the actuation system. Friction model is simulated for different cases. Controller of the system is constructed by two PIDs, one for each of the velocity and the position loops. Velocity feed forward can reduce the time to make a quick move by the system. The disturbance is evaluated from a given road profile and disturbance feed forward is applied to the system.

CHAPTER 1

INTRODUCTION

Weapons used in the battlefield are demanded to be lighter, more mobile, easily controllable and able to shoot with a high accuracy. One of these weapons used in land is the Main Battle Tank (MBT). MBT is probably the most important weapon because of its being mobile, armoured and having heavy-fire capacity. Developments of MBT are parallel to the improvements in heavy weaponry, Weapon Control Systems (WCS) and hull mobility. Heavy weapons have became more effective with the improvements in material science and chemistry. Mounting of these weapons to the hull produces some problems. Control systems become more important while the system become larger and more complex. Drive technology and control systems determine the size of the MBT. Hull mobility depends on the vehicle technology to overcome the problems of cross-country movement. Mobility demands in battlefield lead to the requirement of firing while moving instead of stopping at each time the MBT engages a target. This demand can be achieved by WCS by minimizing the tank's hull movement effects on the barrel.

Director-type system based on the independently stabilized gunner's sight was first developed in 1960s by the Delco Electronic Divisions of General Motors. Chrysler version of this system stabilized position of the gun only in elevation. A simpler alternative to this system was developed by Bofors Aerotronics in Sweden and by Marconi Command and Control Systems in England in the form of a pseudo-director system. The advantage of this system is that it provides a highly stabilized aiming mark without the complexity of an independently stabilized sight and can be applied readily to existing tanks with simple telescopic or periscopic sights mechanically linked to tank guns.

In early tanks used in World War I, free elevation type of mounting was used and it was controlled by a shoulder strap. The disadvantages of this setup are the insufficiently precise control, more human power and very low speed while steering the barrel. This is followed by the use of hydraulic drive systems. After electrical motors were used for slewing the barrel, rapid and precise control has been satisfied. Improvements in traversing the turret were applied to the powered control of the elevation control of tank guns. This adoption has led to the stabilization of the barrel.

1.1 Stabilization of Barrel on a Main Battle Tank

Motion of vehicles causes some unwanted movements on the barrel. These movements must be minimized in order to hit a target while moving. Gunners are expected to minimize this effect especially in elevation by rotating the barrel in the opposite direction of the hull's motion. But the frequency of this kind of motion varies from 0 to 3-4 Hz while the response of the human operators is not more than 0.5 Hz.

In this situation, the effects of vehicle motion on the barrel can be minimized by stabilization systems which are designed to maintain the barrel position according to the earth. Figure 1 and Figure 2 illustrate the problem in detail.

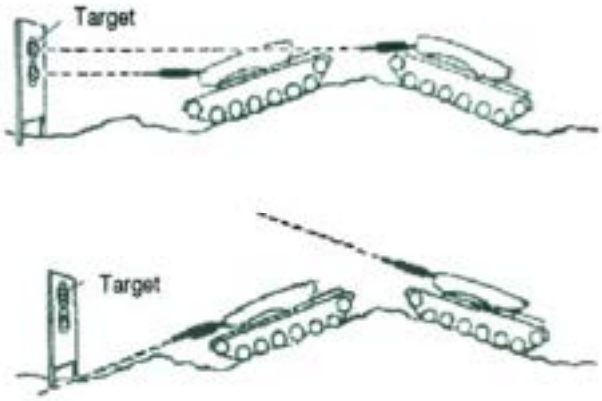

Figure 1.1 Barrel Motion in Elevation

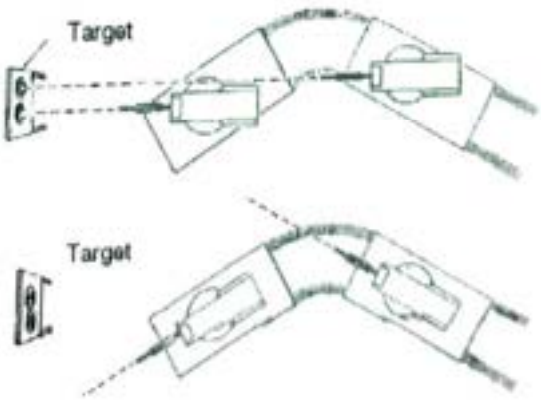

Figure 1.2 Barrel Motion in Azimuth

In 1998, Purdy enhanced the stabilization ratio by using the hull rate gyroscope for feed forward. This study gave the results of the simulations of linear and nonlinear model with and without disturbance feed forward and nonlinear model with feed forward and friction compensation. In another study in 1999, Purdy made a simple elevation model and examined the out of balance effect on WCS. These studies deal about the electrical drive technology. They also have no model in a computer program revealed in the publications.

Systems aimed to do this stabilization basically closed loop servo systems which control the movement of the barrel relative to the earth by using gyroscopes and feedback signals produced by them. Simplest stabilization systems are assigned to cope with the elevation changes and made up of a single closed loop system with a rate gyroscope mounted on the barrel to sense its angular velocity.

Achieving high hitting accuracy for a main battle tank is challenging while the tank is on the move. This can be reached by proper design of a weapon control and gun system. In order to design an effective gun system while the tank is moving, better understanding of the dynamic behaviour of the gun system is required. In this study, the dynamic behaviour of a gun system is discussed in this respect. Both experimental and numerical applications for the determination of the dynamic behaviour of a tank gun system are investigated. Methods such as the use of muzzle reference system (MRS) and vibration absorbers, and active vibration control technology for the control and the reduction of the muzzle tip deflections are also reviewed. For the existing gun systems without making substantial modifications, MRS could be useful in controlling the deflections of gun barrels with estimation/prediction algorithms. The vibration levels could be cut into half by the use of optimised vibration absorbers for an existing gun. A new gun system with a longer barrel can be as accurate as the one with a short barrel with the appropriate structural modifications.

Tank stabilizer is a control system keeping the bore axis in the desired sighting angle. For the control problem of the stabilizer in the case of uncertain parameters, the adaptive control method is introduced to design the vertical tank stabilizer with the nonlinear dynamic model of vertical stabilizer given in the paper. In the design, the multiple parameter uncertainties of the hydraulic servo system are fully considered and the linear feedback control is used to improve the asymptotic stability of the system. The vertical stabilizer of tank is simulated in MATLAB/Simulink environment. In addition, a

numerical structural dynamic characteristics usually show considerable discrepancies with the measured ones because structural details are commonly simplified in the FE models. To identify such discrepancies, FE models of them have been calibrated using the measured dynamic characteristics in previous researches. In this study, the dynamic characteristics were measured for a historic cathedral and the FE model of it was calibrated using the measured results as a reference. Finally, a procedure of the FE model construction for the unreinforced masonry cathedral was tentatively proposed.

1.2 Aims of the Study

In this study, the stabilization of the barrel on a MBT in elevation axis is considered. Only the elevation axis is considered because it is affected much more than the azimuth axis from the road profile. Since a stabilization system improve an ability of hitting targets while the tank is moving without stopping, the effects of disturbances on the barrel should be taken into account. Unbalance caused by mounting the barrel off centre of mass, friction at joint, hydraulic actuator as the driving unit and control system are the causes of using a stabilization system. In this study, all of these components are modelled and simulated under specified conditions.

The brain of the stabilization system is the controller. PID controllers are used to control the position and the velocity of the system. To be able to tune the parameters of the controller, either an experimental setup should be used or a model should be constructed. The use of experimental setup may cause trouble and may be dangerous for the setup. To prevent from these undesired situations such as damaging the system elements, operator injury etc., a model will be constructed and controller parameter tuning and system modifications will be realized by using this model. Since a stabilization system improve an ability of hitting targets while the tank is moving without stopping, the effects of disturbances on the barrel should be taken into account. Finally, the whole system or the elements of it can be used for other design and modernization studies.

1.3 Scope of the Study

It is intended in the study to model the elevation axis of a barrel completely in Simulink 5.0 in Matlab6.5 environment and simulate the disturbance effects on it. This model includes barrel, hydraulic actuator as driving unit, an electro-hydraulic servo valve to manipulate the actuator and controller unit. The properties of the servo valve used to

control flow are explained. System identification is made for the servo valve by using its experimental test outputs to determine the valve gain and the time constant. The nonlinear flow characteristics of the servo valve are derived and modelled.

The actuation system as a slider-crank mechanism is modelled. Inverse kinematics is used to solve the relation between the barrel's angular position and the actuator position while the motion is transformed from translational movement to rotational. There are a lot of parameters which define the barrel's motion such as frictions in the barrel joint, the compressibility of the hydraulic fluid, unbalance caused from mounting point of the barrel to the hull and inertia. The controller is made up of two PID's one for each loop feeding back the velocity and the position of the barrel. The disturbance caused by the road and transferred over the hull is modelled. The stabilization method to overcome the disturbance which can be measured by means of gyroscopes is examined.

To provide appropriate feed forward signals two gyroscopes are mounted one to the hull and the other to the barrel. The use of the feed forward control was pioneered by the Cadillac Cage Company in the late 1950s. This stabilization system was demonstrated in 1962 and firstly adopted to the Leopard I Tanks in 1969-1970 by German and Belgian Armies. Feed forward control application was seen in Soviet Army with a difference from the others. The stabilization systems include rate integrating gyros which provide a memory for the barrel position. So the barrel can be driven to the old position just before the disturbance.

The properties of the servo valve used to control flow are explained. System identification is made for the servo valve by using its experimental test outputs to determine the valve gain and the time constant. The nonlinear flow characteristics of the servo valve are derived and modelled. The actuation system as a slider-crank mechanism is modelled. Inverse kinematics is used to solve the relation between the barrel's angular position and the actuator position while the motion is transformed.

CHAPTER 2

LITERATURE REVIEW

2.1 System modelling

Modelling is the starting point of design, production, test and control. A good modelling will settle most of the problems in the design step. Also in the production case, modelling will help to define many of the criteria. The test and control stages are also critical. Because of many restrictions, the control and the test stages are realized in a tight manner. On the other hand with a well designed model, tests can be made on the model without any damage risk to the system. All critical values can be tested and determined in this way. While modelling, it should not be forgotten that the more the properties introduced to the model the more the problems occur. If all the parameters of the real system were tried to be included in the model, this would probably generate many problems such as the increase in the number of the logical operators, time spent for the evaluation, solver errors caused by the time step and more computer capabilities need etc. Sometimes modelling so many details becomes harmful instead of being helpful as the system may not be settled with the desired accuracy because of the problems mentioned above. While modelling, critical case is to determine the modelling criteria and assumptions. While constructing the elevation axis model, the following assumptions are made:

- There is a stable source of hydraulic fluid supply at constant pressure.
- Effects of hydraulic fluid inertia are negligible.
- Gage pressures are used.
- No temperature change exists.
- There is no leakage.

2.1.1 System Model

In this study, the "system" will represent the union of the servo valve, the actuator and the barrel. Hull dynamics is not included in the system mentioned in this study. While it is assumed that road profile is known and correctly transformed via the gyroscopes on

the hull, it is included in the system as disturbance representing the hull motion. Input of the system is the velocity command to the servo valve.

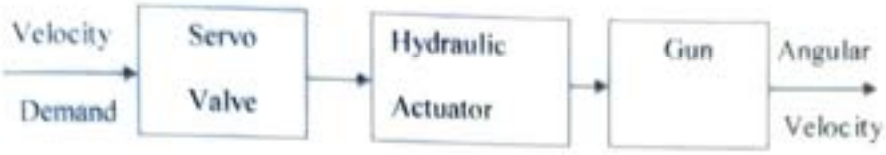

Figure 2.1 Block Diagram Representation of Barrel

The test and control stages are also critical. Because of many restrictions, the control and the test stages are realized in a tight manner. On the other hand with a well designed model, tests can be made on the model without any damage risk to the system. All critical values can be tested and determined in this way. While modelling, it should not be forgotten that the more the properties introduced to the model the more the problems occur. If all the parameters of the real system were tried to be included in the model, this would probably generate many problems such as the increase in the number of the logical operators, time spent for the evaluation, solver errors caused by the time step and more computer capabilities need etc.

Sometimes modelling so many details becomes harmful instead of being helpful as the system may not be settled with the desired accuracy because of the problems mentioned above.. A good modelling will settle most of the problems in the design step. Also in the production case, modelling will help to define many of the criteria.

The actuation system as a slider-crank mechanism is modelled. Inverse kinematics is used to solve the relation between the barrel's angular position and the actuator position while the motion is transformed from translational movement to rotational. There are a lot of parameters which define the barrel's motion such as frictions in the barrel joint, the compressibility of the hydraulic fluid, unbalance caused from mounting point of the barrel to the hull and inertia. The controller is made up of two PID's one for each loop feeding back the velocity and the position of the barrel. The disturbance caused by the road and transferred over the hull is modelled. The stabilization method to overcome the disturbance which can be measured by means of gyroscopes is examined.

While modelling, it should not be forgotten that the more the properties introduced to the model the more the problems occur. If all the parameters of the real system were tried to be included in the model, this would probably generate many problems such as the increase in the number of the logical operators, time spent for the evaluation, solver errors caused by the time step and more computer capabilities need etc.

2.1.2 Servo Valve Model

A classical four way, zero-lapped valve is used to excite the actuator. The servo valve has 3 stages: flapper as first, spools as second and third stages. A schematic representation of the valve used in this study is seen in Figure 4.

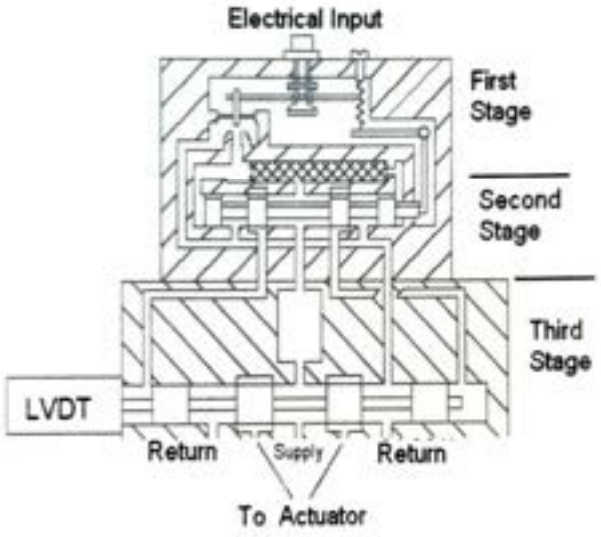

Figure 2.2 Schematic Representation of Servo Valve Block

The first stage is an electrically driven flapper nozzle type. The flapper moves by the force generated from the induction of two coils by DC current. In the first stage the input is the current and the output is the flapper position. The flow characteristics are nonlinear but there is no chance to determine the position and the exact flow. By assuming that the force acting on the spool caused by the pressure in the chamber is proportional to the flapper position, it can be illustrated by a constant which will be the gain of the transfer function between the flapper and the spool position. In this block diagram, valve dynamics represents all three stages together. While the parameters of the electrical stages cannot be evaluated, only the nonlinearity in the third stage is taken into account and the rest of the

system is included in the transfer function of the plant. The output of the LVDT is measured and the flow rate is calculated from this value via orifice equation.

$$Q = C_d W X_3 \sqrt{2/p}\,(p1 - p2) \qquad \ldots (2.1)$$

In second stage, the input is the flapper position and the output is the spool position. In this case, also there is no chance to determine the position of the spool and the exact flow. At the third stage the position of the second stage spool is the input and third stage spool position is the output this is clearly illustrated through diagrammatic representation. But a modelling servo valve is almost impossible while the parameters like mass, friction and stiffness of the stages separately are unknown. There is no chance to make individual tests for each stages of the valve. But, it is possible to determine the overall characteristics of the valve considering all three stages together. In these tests realized in ASELSAN just Linear Variable Differential Transducer (LVDT) outputs can be measured and recorded. LVDT is a device which determines the position of the spool.

A Servo Stabilizer is a Servo motor controlled stabilization system that performs optimum voltage supply using a Buck\Boost transformer booster that captures voltage fluctuations from input and regulates current to the correct output. An AC synchronous motor adjusts voltage in clockwise or anticlockwise direction and manages the output voltage with components like control card, dimmer, comparator, transistors, etc. The Servo stabilizer has definitely an edge over traditional stabilizers. Basically there are two types of stabilizers, one is relay based and the other is Servo based. In relay stabilizer, a switch corrects the output voltage accuracy at ±10%. But in Servo, the primary Servo motor corrects supply using buck-boost function. This type of stabilizer is beneficial for high output voltage accuracy. It provides ±1 % voltage output where input voltage alters up to ± 50 %. This type supports up to 5000 KVA & above so it has a higher load capacity. Ultimately, the major difference between the two is performance as Servo is a step less correction technologically superior to traditional relay transformers and gives accurate output. A servo stabilizer is a popular replacement for low high rating appliances used in both commercial and residential places, homes and industries that provides unmatched voltage supply to protect your fragile equipments. Servo has both single-phase and three-phase systems coming in Oil cooled and Air-cooled units.

2.1.2.1 System Identification

Computer simulations of systems give the opportunity to the users to study on the computer to make the design instead of constructing real systems. But it should not be expected that the response of the simulations will be the same as the real system even parameters of the real system are known.

Matlab and similar programs introduce us many methods to identify the systems. System Identification. The output plots can be seen in the figure. The valve was controlled by a PID while the position of the third stage spool (LVDT) is fed back.

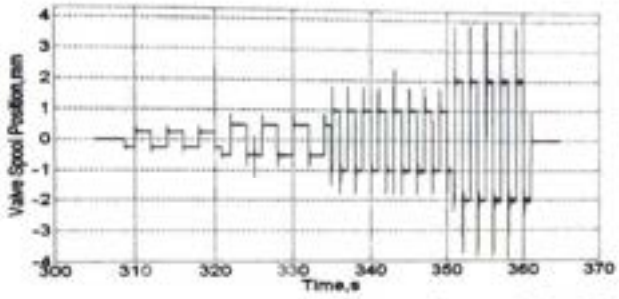

Figure 2.3 The LVDT Output of Servo Valve Test

In this study, this identification is repeated while taking the input as the position demand corresponding to the electrical input in mm. As seen in figure 5there are transition periods and some disturbances which cannot be used in identification. By omitting the transient periods and extraordinary fluctuations, step responses are obtained and plotted on the same graph in Figure 14 for one second duration, which is an enough period for settling.

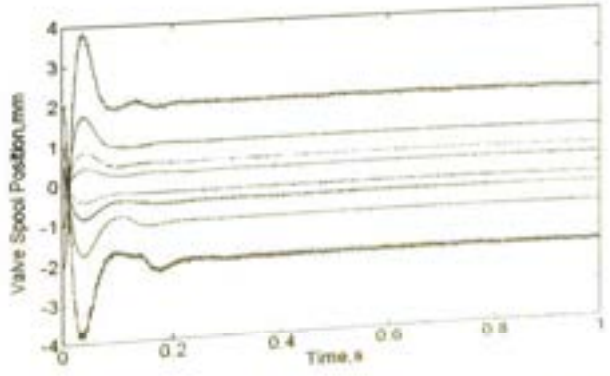

Figure 2.4 Servo Valve Step Responses for Different Input Values

As can be seen in figure 2.4, valve step responses differ from each other. Valve shows different dynamic behaviours at different amplitudes. In this situation, although identification will fit exactly to one of the step response, it would not be the optimum solution for the other magnitudes. Thus, the solution differs also at each amplitude. Anyone of the valve gain and time constant pairs for these step responses could not represent all of the step responses with the same accuracy. "m" files used in the simulations and calculation

2.1.2.2 Load Pressure Feedback

The servo valve is used to control the velocity of the actuator. Pressure feedback is a way of adding damping to this subsystem. Pressure feedback is able to increase damping based on the fact that the cylinder pressure is related to the derivative of the cylinder velocity. Feeding back the derivative of the cylinder velocity increases the damping of the system, thus improves the transient performance. The only problem with this strategy is that the pressure information also contains the effect of external forces. A high-pass pressure filter is introduced to deal with this problem. A high-pass pressure filter is introduced to deal with this problem.

Fluid power systems are inherently nonlinear and typically suffer from very poor damping. Despite these characteristics, it is not uncommon that traditional linear type controllers are applied. This typically results in conservative adjustment of the controllers, or when more advanced controllers are applied, that they do not benefit from the possibilities for improving the damping by applying (internal) pressure feedback in the systems. In both cases, the result will be degraded performance compared with what may be obtained. Pressure feedback, also referred to as active damping, is not a new method. However, it is an often overlooked method, and when it is applied, it is not adjusted optimally to also account for model uncertainties, unmodelled system dynamics, and parameter variations. The focus of this paper is to explain various types of pressure feedback that may be applied; how these affect a given system, and how to adjust the parameters of the pressure feedback to obtain the best results. This is done for both a traditional symmetric cylinder servo system and a system with a differential cylinder using both pressure and non pressure compensated proportional valves. Based on the presented models, the analysis yields results for how to properly adjust the parameters.

The mechanism usually includes an angular reference device such as a mechanical or optical gyro and servo mechanisms. In the case of a tank, there is one servo stabilizing the turret and another for the elevation of the gun. The aiming is then done by control input to the mechanism, rather than directly on the gun. The control mechanism usually has other functions, such as applying super-elevation and leading the target according to its velocity, making it a fire-control system, and some guns are entirely automatic.

The G value can be set through a wide range. Mostly, this parameter is selected for each specific system application separately and influenced by various system requirements such as system frequency, response and stiffness generally corresponds to a corner frequency of about 1/3 of resonant load frequency, f_c. Vibration tests were made for MBT to determine the critical frequencies. For the MBT the tests are made in a project in ASELSAN. Barrel's natural frequency is determined in these tests as 10.73 Hz.

2.1.2.3 Dither Signal

Behaviour of a hydraulic servo valve can be unpredictable because of striation which keeps the valve spool from moving when input signal changes are small. When the signal finally becomes large enough to initiate a movement, the spool will tend to overshoot the position required for accurate control. Dither is a rapid, small movement of the spool around the desired position. It is intended to keep the spool moving to avoid striation. Dither amplitude must be large enough and the frequency slow enough for the spool to respond, and yet small and fast enough to avoid creating a noticeable pulsation in the hydraulic output of the valve.

The amplitude of the ripples determines whether, or how far, the spool will move at a given frequency. Dither is utilized in many different fields where digital processing and analysis are used. If that error is correlated to the signal, the result is potentially cyclical or predictable. In some fields, especially where the receptor is sensitive to such artifacts, cyclical errors yield undesirable artifacts. In these fields introducing dither converts the error to random noise. The field of audio is a primary example of this. The human ear functions much like a Fourier transform, wherein it hears individual frequencies. The ear is therefore very sensitive to distortion, or additional frequency content, but far less sensitive to additional random noise at all frequencies such as found in a dithered signal. Dither is added before any quantization or re-quantization process, in

order to de-correlate the quantization noise from the input signal and to prevent non-linear behaviour (distortion). Quantization with lesser bit depth requires higher amounts of dither. The result of the process still yields distortion, but the distortion is of a random nature so the resulting noise is, effectively, de-correlated from the intended signal.

If the signal being dithered is to undergo further processing, then it should be processed with a triangular-type dither that has an amplitude of two quantisation steps; for example, so that the dither values computed range from, say, −1 to +1, or 0 to 2. This is the "lowest power ideal" dither, in that it does not introduce noise modulation (which would manifest as a constant noise floor), and completely eliminates the harmonic distortion from quantisation. If a coloured dither is used instead at these intermediate processing stages, then frequency content may bleed into other frequency ranges that are more noticeable, which could become distractingly audible. If the signal being dithered is to undergo no further processing if it is being dithered to its final result for distribution then a coloured dither or noise shaping is appropriate. This can effectively lower the audible noise level, by putting most of that noise in a frequency range where it is less critical.

Dithering is used in computer graphics to create the illusion of colour depth in images with a limited colour palette - a technique also known as colour quantization. In a dithered image, colours that are not available in the palette are approximated by a diffusion of coloured pixels from within the available palette. The human eye perceives the diffusion as a mixture of the colours within it. Dithered images, particularly those with relatively few colours, can often be distinguished by a characteristic graininess or speckled appearance.

By its nature, dithering introduces pattern into an image the theory being that the image will be viewed from such a distance that the pattern is not discernible to the human eye. Unfortunately this is often not the case, and often the patterning is visible. In these circumstances it has been shown that a blue noise dither pattern is the least unsightly and distracting. The error diffusion techniques were some of the first methods to generate blue noise dithering patterns. However, other techniques such as ordered dithering can also generate blue noise dithering without the tendency to degenerate into areas with artifacts.

The dither signal can be applied to the system by adding this signal to the control command. It is usually about 25-300 Hz and magnitude is the 10 % of the reference control signal. In addition to this property, the dither signal prevents the contamination

near the orifices inlets which work very little openings. Command signal used in the system is 10 V for the full opening of the servo valve. The 10 % of this value corresponds to the peak-to-peak value of the amplitude of the dither signal. Dither signal used in this model is a sine wave with amplitude 0.5 V at 140 Hz.

2.1.3 Actuator Model

An actuator is a component of a machine that is responsible for moving and controlling a mechanism or system, for example by opening a valve. In simple terms, it is a mover. An actuator requires a control signal and a source of energy. The control signal is relatively low energy and may be electric voltage or current, pneumatic or hydraulic pressure, or even human power. Its main energy source may be an electric current, hydraulic fluid pressure, or pneumatic pressure. When it receives a control signal, an actuator responds by converting the signal's energy into mechanical motion. An actuator is the mechanism by which a control system acts upon an environment. The control system can be simple (a fixed mechanical or electronic system), software-based (e.g. a printer driver, robot control system), a human, or any other input.

This electromechanical linear actuator is designed to improve stabilization and pointing accuracy for existing and new turret applications. This series of linear actuators is designed to meet and exceed the demanding requirements of modern main battle tanks or Howitzer gun laying systems. Features include a built-in integrated equilibrator for highly unbalanced weapons, roller screw linear output, brushless DC motor, and 24 volt clutch and maintenance motor for remote operation.

A hydraulic actuator consists of cylinder or fluid motor that uses hydraulic power to facilitate mechanical operation. The mechanical motion gives an output in terms of linear, rotatory or oscillatory motion. As liquids are nearly impossible to compress, a hydraulic actuator can exert a large force. The drawback of this approach is its limited acceleration.

The hydraulic cylinder consists of a hollow cylindrical tube along which a piston can slide. The term single acting is used when the fluid pressure is applied to just one side of the piston. The piston can move in only one direction, a spring being frequently used to give the piston a return stroke. The term double acting is used when pressure is applied on

each side of the piston; any difference in pressure between the two sides of the piston moves the piston to one side or the other.

Pneumatic actuators enable considerable forces to be produced from relatively small pressure changes. A pneumatic actuator converts energy formed by vacuum or compressed air at high pressure into either linear or rotary motion. Pneumatic energy is desirable for main engine controls because it can quickly respond in starting and stopping as the power source does not need to be stored in reserve for operation. Moreover, pneumatic actuators are safer, cheaper, and often more reliable and powerful than other actuators. These forces are often used with valves to move diaphragms to affect the flow of air through the valve

Hydraulic actuator used in the system in this study is a double acting type. The flow from the valve fills the actuator and pressurizes one side of the cylinder. Force required for the motion is produced by this pressurized liquid acting on the piston. Actuator motion, fluid compressibility, actuator stiffness and the leakage in the actuator define the flow rate directly. Finally the assumptions made while modelling the actuator is as follows.

- Temperature change in the fluid is neglected.
- Cylinder and pressurized lines are absolutely rigid.
- Piston mass is negligible. (Because barrel mass is too large)
- There is no internal leakage in the actuator.
- Compressibility is taken into consideration while volumes in the cylinder and its lines are too big compare to the servo valve.

The compressibility is taken into consideration only while modelling the actuator because volumes in the actuator and pressurized lines are too large than the volumes in the servo valve. The output of the system is the barrel's angular position: input is the desired angular position of the barrel relative to the hull. On the other hand slider-crank has a translational input and a rotational output. The unknown parameter which is the variable edge of the triangle for this mechanism is the length of the actuator.

An electric actuator may provide the actuation force/torque in one of several ways. Electromechanical actuators may be used to power a motor that converts electrical energy into mechanical torque. Another approach is an electro hydraulic actuator, where

the electric motor remains the prime mover, but provides torque to operate a hydraulic accumulator that is then used to transmit actuation force in much the same way that diesel engine/hydraulics are typically used in heavy equipment. Electrical energy is used to actuate equipment such as multi-turn valves, or electric-powered construction and excavation equipment.

Additionally, a brake is typically installed above the motor to prevent the media from opening valve. If no brake is installed, the actuator will uncover the opened valve and rotate it back to its closed position. If this continues to happen, the motor and actuator will eventually become damaged. Electric actuators are one of the cleanest and most readily available forms of actuator because it does not directly involve oil or other fossil fuels. An electric actuator may provide the actuation force/torque in one of several ways. Electromechanical actuators may be used to power a motor that converts electrical energy into mechanical torque. If no brake is installed, the actuator will uncover the opened valve and rotate it back to its closed position. If this continues to happen, the motor and actuator will eventually become damaged. Electric actuators are one of the cleanest and most readily available forms of actuator because it does not directly involve oil or other fossil fuels.

Twisted and Coiled Polymer (TCP) actuator also known as Super Coiled Polymer (SCP) actuator is a coiled polymer that can be actuated by electric power. A TCP actuator looks like a helical spring. TCP actuators are usually made from silver coated Nylon. TCP actuators can also be made from other electrical conductance coat such as gold. TCP actuator should be under a load to keep the muscle extended. The electrical energy transforms to thermal energy due to electrical resistance, which is also known as Joule heating, ohmic heating and resistive heating. As the temperature of the TCP actuator increases by Joule heating, the polymer contracts and it causes the actuator contraction. A mechanical actuator functions to execute movement by converting one kind of motion,

such as rotary motion, into another kind, such as linear motion. An example is a rack and pinion. The operation of mechanical actuators is based on combinations of structural components.

Soft actuators are being developed to handle fragile objects like fruit harvesting in agriculture or manipulating the internal organs in biomedicine that has always been a challenging task for robotics. Unlike conventional actuators, soft actuators produce flexible motion due to the integration of microscopic changes at the molecular level into a macroscopic deformation of the actuator materials.

The majority of the existing soft actuators are fabricated using multistep low yield processes such as micro-moulding, solid freeform fabrication, and mask lithography. However, these methods require manual fabrication of devices, post processing/assembly, and lengthy iterations until maturity in the fabrication is achieved. To avoid the tedious and time-consuming aspects of the current fabrication processes, researchers are exploring an appropriate manufacturing approach for effective fabrication of soft actuators. Therefore, special soft systems that can be fabricated in a single step by rapid prototyping methods, such as 3D printing, are utilized to narrow the gap between the design and implementation of soft actuators, making the process faster, less expensive, and simpler. They also enable incorporation of all actuator components into a single structure eliminating the need to use external joints, adhesives, and fasteners.

These result in a decrease in the number of discrete parts, post-processing steps, and fabrication time. 3D printed soft actuators are classified into two main groups namely "semi 3D printed soft actuators" and "3D printed soft actuators". The reason for such classification is to distinguish between the printed soft actuators that are fabricated by means of 3D printing process in whole and the soft actuators whose parts are made by 3D printers and post processed subsequently. This classification helps to clarify the advantages of 3D printed soft actuators over the semi 3D printed soft actuators due to their capability of operating without the need of any further assembly.

The output of the system is the barrel's angular position; input is the desired angular position of the barrel relative to the hull. On the other hand slider-crank has a translational input and a rotational output. The unknown parameter which is the variable edge of the triangle for this mechanism is the length of the actuator.

2.1.4 Barrel Model

Rifled barrels introduce ambiguity to measurement of caliber. A rifled bore consists of alternating grooves and lands. The distance across the bore from groove to groove is greater than the distance from land to land. Projectiles fired from rifled barrels must be of the full groove to groove diameter to be effectively rotated by the rifling, but the caliber has sometimes been specified as the land to land diameter before rifling grooves were cut. The depth of rifling grooves (and the consequent ambiguity) increases in larger calibers. Steel artillery projectiles may have a forward bourrelet section machined to a diameter slightly smaller than the original land to land dimension of the barrel and a copper driving band somewhat larger than the groove to groove diameter to effectively seal the bore as it becomes enlarged by erosion during prolonged firing. United States Navy guns typically used rifling depth between one-half and one percent of caliber. Projectile bourrelet diameter specification was 0.015 inches (0.38 mm) less than land to land diameter with a minus manufacturing tolerance so average clearance was about 0.012 inches (0.30 mm). Driving band diameter was groove to groove diameter plus 0.02 inches (0.51 mm).

Early gun barrels were short and thick, typically no more than 26 calibers, as the gunpowder propellant they used burned very quickly and violently, and hence its acceleration time was short. Slower-burning brown powder formulations of gunpowder allowed gun barrel length to increase slightly in the 1880s but enormous quantities of brown powder were required. New slower-burning smokeless powder propellants available from the 1880s onwards such as Poudre B, cordite and nitrocellulose allowed a gentler prolonged acceleration, hence gun barrels were made progressively longer and thinner. The new formulations were far more powerful propellants than gunpowder and far less was needed by weight as they transformed almost entirely to gasses when burned. Muzzle velocity became limited only by the length of barrel that was feasible, both in terms of the construction methods of the day and in terms of any practical constraints imposed by the gun's manner of use.

The practical effect of long barrels for modern guns is that the projectile spends more time in the barrel before it exits, and hence more time is available for expanding gas from the controlled burning of the propellant charge to smoothly accelerate the projectile, bringing about a higher velocity without placing undue strain on the gun. In internal ballistics terms, if the base of a projectile is thought of as a piston propelled by the

expanding gas, then as barrel length increases the volume swept by the piston also increases, and hence the amount of energy that can be extracted from the gas's burning increases. A longer barrel allows more propellant to be used: the propellant is all burned fairly early in the projectile's journey along the barrel, except in the very common instance where combustion is still occurring as the projectile leaves the muzzle and a visible muzzle flash is produced.

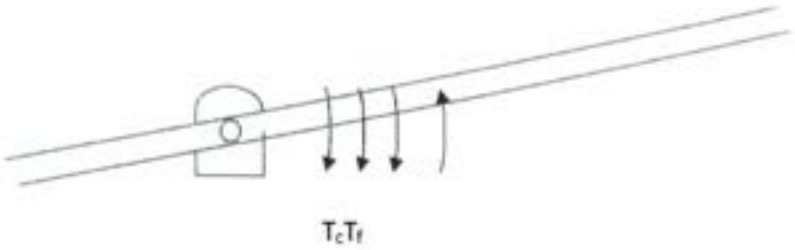

Figure 2.5 Torques acting on the Barrel

There are two hard-stops which limit the rotation of the barrel with respect to the hull at +20° and -10°. Hence these limits are relative to the hull. Also the joint between the barrel and the hull is not located at the centre of gravity of the barrel and has both Coulomb and viscous friction. Geometrical structure of the actuation system, frictions and unbalance cause nonlinearity. In addition to the general assumptions, the barrel is assumed to be absolutely rigid. While modelling, causality must be carefully followed. To be able to start the motion, static friction, T_c, must be overcame. Thus, in determining the situation whether "stick" or "move", coulomb friction will be the first check point.

Another decision should be made about whether the barrel continues its motion or stops. Relative velocity and the position of the barrel are criteria for this case. Barrel sticks to the hull when any of the two conditions are satisfied. These two conditions are considered at the same time. One is the position check of the barrel whether it touches the hard-stops or not and the other is the velocity comparison of the inner part with the outer oneIn this case, outer part has an angular velocity and it is known. There is viscous friction, represented by b_g, and static friction, T_c between the outer and the inner part. Resultant torque, T_c^*, was defined before.

The projectile continues to accelerate as long as the pressure behind it is sufficient to overcome bore friction. The excess energy will continue to accelerate the projectile until

it exits the muzzle. If the pressure behind the projectile drops sufficiently before the projectile leaves the bore, the projectile can and will slow while still within the barrel, despite residual bore pressure behind the projectile. A light charge with insufficient pressure to expel the projectile will result in a squib, or projectile lodged in the bore. This pressure is reduced by the increasing barrel volume the gas has to fill, and in order to achieve maximum muzzle velocity with the shortest barrel length, the projectile should exit the barrel as the gas pressure reduces to a small fraction of the maximum, although unlike chamber maximum chamber pressure, the small fraction desired is impossible to measure. In modern guns, increased muzzle velocities can be produced by altering powder composition and/or using duplex charges containing two different powders in order to extend the pressure curve further down the bore. By exposing the projectile base to a given pressure for a longer length of time, velocity can be increased without elevating the pressure level generated.

2.1.4.1. Unbalance Effect

The unbalance is the result of the mounting the barrel to the hull from anywhere except its centre of mass. Its effect on the barrel is an additional torque proportional to the displacement between the centre of mass and the mounting and the angular position of the barrel with respect to the hull. The hull is assumed always parallel to the ground.

However, this is not the only factor which cause torque on the barrel in vertical axis. While the tank moves on a curved surface, it rotates around an instantaneous center of rotation of ground profile. This affects the barrel as disturbance which is an angular velocity. The rate of change of the angular velocity, □$_d$ is the acceleration and causes torque in the system in the opposite direction with the angular velocity.

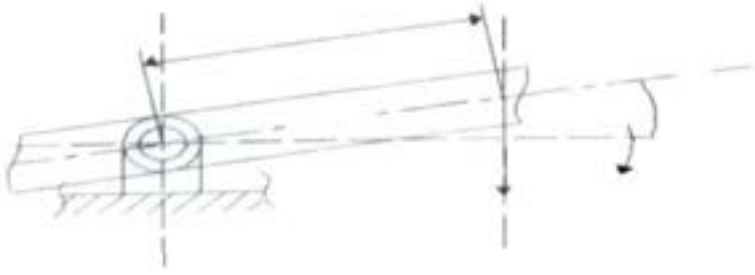

Figure 2.6 Unbalance Effect on the Barrel

Having achieved a breakthrough of the enemy's line, units comprising the Schwerpunkt were not supposed to become decisively engaged with enemy front line units to the right and left of the breakthrough area. Units pouring through the hole were to drive upon set objectives behind the enemy front line. In World War II, German Panzer forces used motorised mobility, to paralyse the opponent's ability to react. Fast-moving mobile forces seized the initiative, exploited weaknesses and acted before opposing forces could respond. Central to this was the decision cycle . Through superior mobility and faster decision-making cycles, mobile forces could act quicker than the forces opposing them. Directive control was a fast and flexible method of command. Rather than receiving an explicit order, a commander would be told of his superior's intent and the role which his unit was to fill in this concept. The method of execution was then a matter for the discretion of the subordinate commander. Staff burden was reduced at the top and spread among tiers of command with knowledge about their situation. Delegation and the encouragement of initiative aided implementation, important decisions could be taken quickly and communicated verbally or with brief written orders.

Close air support was provided in the form of the dive bomber and medium bomber. They would support the focal point of attack from the air. German successes are closely related to the extent to which the German Luftwaffe was able to control the air war in early campaigns in Western and Central Europe, and the Soviet Union. However, the Luftwaffe was a broadly based force with no constricting central doctrine, other than its resources should be used generally to support national strategy. It was flexible and it was able to carry out both operational-tactical and strategic bombing. Flexibility was the Luftwaffe's strength in 1939–1941. Paradoxically, from that period onward it became its weakness. While Allied Air Forces were tied to the support of the Army, the Luftwaffe deployed its resources in a more general, operational way. It switched from air superiority missions, to medium-range interdiction, to strategic strikes, to close support duties depending on the need of the ground forces. In fact, far from it being a specialist panzer spearhead arm, less than 15 percent of the Luftwaffe was intended for close support of the army in 1939.

CHAPTER 3

CONTROL STRATEGIES FOR DISTURBANCE REJECTION

Although different systems are designed to perform different functions, all of them have to meet some common requirements. Main characteristics of typical system concern accuracy speed of response and output sensitivity to component and environmental changes. The priority of importance of these characteristics is defined by the designer based on the system nature and its application. These characteristics are used to measure the performance of the system. But the primary concern is the stability of the system.In this study, all of the criteria were tried to be satisfied but according to this specific application most important performance criteria is disturbance rejection in other words stabilization of the barrel in the elevation axis when the MBT moves on a bumpy road.

3.1. Controller

System has two outputs to be controlled namely the angular velocity and the position. Each loop, which are constructed by feeding back the system output to the comparison with the desired value, is controlled by a PID controller. The position and the velocities in the system are measured by different devices. The device used for measuring the velocity is a classical mechanical gyroscope both for the barrel and the hull. The position of the barrel is measured by an inclinometer. At first look, it seems meaningless but the feedback signals are supplied from different sources. The gyro-scopes used in the system have a bandwidth of 30 Hz and a damping ratio of 0.7. Although they are relevant, in industrial applications controllers could be used in this way.

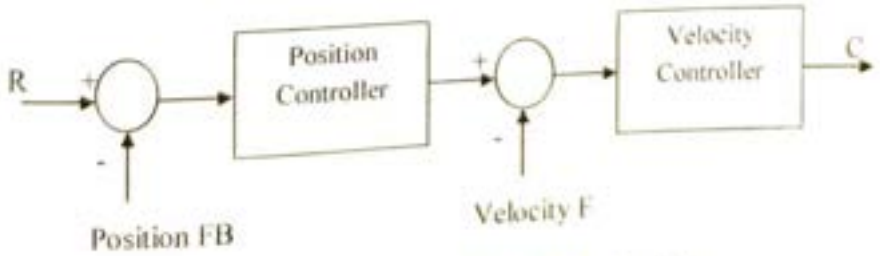

Figure 3.1 Classical Control Algorithm

3.2. Disturbance Feed Forward

Many process control loops are affected by large disturbances. Feedback control can act only on the result of a disturbance, which means feedback control cannot do anything until the process variable has been affected by the disturbance. Changes in process flow rate will be a major source of disturbances to the outlet temperature. If the process flow rate through the heater is increased, the original steam flow rate will not be enough to heat up the increased amount of process liquid and the outlet temperature will decrease. Feedback control will eventually increase the steam flow rate and bring the outlet temperature back to its set point, but not until there has been a significant deviation in temperature. Review your controller documentation and take special care with scaling the feed forward signal. Many PID controllers expect the feed forward signal to be scaled between -100% and +100%.

As the definition of disturbance, it is unwanted that adversely affect the desired output. Although the effect of disturbances on the system cannot be eliminated completely, it can bereduced. Frequency response of the system is analyzed to be able define the transfer function, G_u, between the command signal and the output.

Identification of the disturbance transfer function, G_d, and the transfer function of the nominal plant are made by using the frequency response. This identification is made on the Simulink model. In tests, system is separated from the controller and naturally from the loops. System is used as open loop. Only servo valve position feedback, LVDT is closed. Coulomb friction is neglected. Both input command to the open loop system and disturbance. Feed forward and feedback control is often combined with cascade control, to ensure that their control actions manipulate the physical process linearly, eliminating control valve nonlinearities and mechanical problems. If several major disturbances exist, a feed forward controller can be implemented for each of them. The outputs of all the feed forward controllers can be added together to produce one final feed forward signal. Feed forward, sometimes written feed forward, is a term describing an element or pathway within a control system that passes a controlling signal from a source in its external environment to a load elsewhere in its external environment. This is often a command signal from an external operator.

A control system which has only feed-forward behaviour responds to its control signal in a pre-defined way without responding to how the load reacts; it is in contrast with a system that also has feedback, which adjusts the output to take account of how it affects the load, and how the load itself may vary unpredictably; the load is considered to belong to the external environment of the system. In a feed-forward system, the control variable adjustment is not error-based. Instead it is based on knowledge about the process in the form of a mathematical model of the process and knowledge about or measurements of the process disturbances.

Some prerequisites are needed for control scheme to be reliable by pure feed-forward without feedback: the external command or controlling signal must be available, and the effect of the output of the system on the load should be known (that usually means that the load must be predictably unchanging with time). Sometimes pure feed-forward control without feedback is called ballistic, because once a control signal has been sent, it cannot be further adjusted; any corrective adjustment must be by way of a new control signal. In contrast, 'cruise control' adjusts the output in response to the load that it encounters, by a feedback mechanism.

3.3 Feed forward in Voltage loops

There are three types of control systems: open loop, feed-forward, and feedback. An example of a pure open loop control system is manual non-power-assisted steering of a motor car; the steering system does not have access to an auxiliary power source and does not respond to varying resistance to turning of the direction wheels; the driver must make that response without help from the steering system. In comparison, power steering has access to a controlled auxiliary power source, which depends on the engine speed. When the steering wheel is turned, a valve is opened which allows fluid under pressure to turn the driving wheels. A sensor monitors that pressure so that the valve only opens enough to cause the correct pressure to reach the wheel turning mechanism. This is feed-forward control where the output of the system, the change in direction of travel of the vehicle, plays no part in the system. See Model predictive control.

Feed forward control is distinctly different from open loop control and teleoperator systems. Feed forward control requires a mathematical model of the plant (process and/or machine being controlled) and the plant's relationship to any inputs or feedback the system might receive. Neither open loop control nor teleoperator systems

require the sophistication of a mathematical model of the physical system or plant being controlled. Control based on operator input without integral processing and interpretation through a mathematical model of the system is a teleoperator system and is not considered feed forward control.

CHAPTER 4

SIMULATION

In this chapter, Simulink models of the system components will be constructed and explained. Especially, servo valve identification and the friction model are handled in detail. Finally the complete system will be simulated for different cases. The simulations are made with a fixed time step of $5x10^{-4}$ s and the ODE5 (Dormant-Prince) solver is used. Because the fastest component of the system is the servo valve and its time constant is 0.0032 s. Since time step is very small, solution method also is selected 5^{th} order to be able to prevent the valuation error.

4.1. Valve Model and Identification Results

As explained in Chapter 2, the valve is separated into 2 parts. First part is made up of the linearized section which has the transfer function between the input voltage and the output valve's third stage spool position. Second part is the section where the flow is determined which maintains the nonlinearity of the orifices. By combining these two blocks complete servo valve block is constructed. At this time, load pressure feedback is added to the valve. Load Pressure is fed back via a pressure transducer and high pass filter. High pass filter time constant is determined according to the load resonant frequency is 0.445 s. Scale for the input rad/s to mm is found by simulating the complete system with different inputs and takes the ratios with the angular velocity output. Corresponding valve openings are determined and the scale is obtained.

By combining these two blocks complete servo valve block is constructed. At this time, load pressure feedback is added to the valve. Load Pressure is fed back via a pressure transducer and high pass filter. High pass filter time constant is determined according to the load resonant frequency which is mentioned as 0.445 s. Scale for the input rad/s to mm is found by simulating the complete system with different inputs and takes the ratios with the angular velocity output. Corresponding valve openings are determined and the scale is obtained. At this time, load pressure feedback is added to the valve. Load Pressure is fed back via a pressure transducer and high pass filter. Since time step is very small, solution method also is selected 5^{th} order to be able to prevent the valuation error.

4.1.1. Valve Identification

Servo valve is made up of three stages but there were the LVDT output and the command voltage as the input. The number of the step responses in Figure 14 was not equal for each amplitude. While the mean value will be determined, this inequality gives wrong weigh to the magnitudes. Identification is made by using the cost function via an "m" file which calculates the error between the simulation and the actual response by simulating the servo valve model with different gain and time constant parameters. In this calculation two actual step response data are used for each amplitude. Minimum error surface and the simulations with the parameters found in this case were plotted.

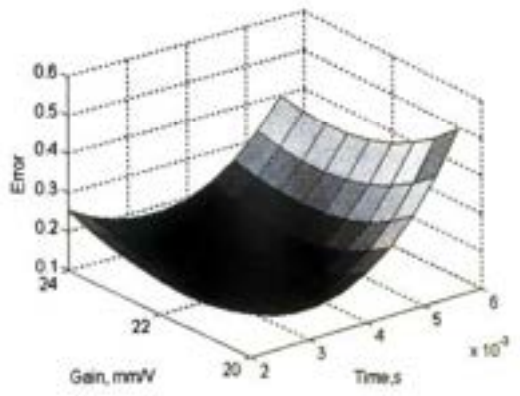

Figure 4.1 Error Surface for Servo Valve Identification

After these calculations, gain value, K, is found 21.8 and time constant, T, is found 0.0032 s. Identification is made by using the cost function via an "m" file which calculates the error between the simulation and the actual response by simulating the servo valve model with different gain and time constant parameters. Servo valve is made up of three stages but there were the LVDT output and the command voltage as the input. The number of the step responses in Figure 14 was not equal for each amplitude. Load Pressure is fed back via a pressure transducer and high pass filter. High pass filter time constant is determined according to the load resonant frequency is 0.445 s.

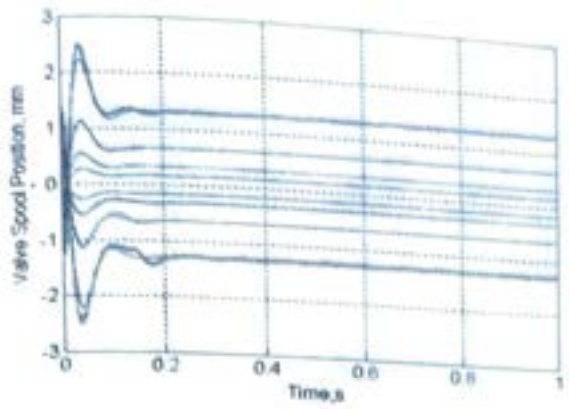

Figure 4.2 Servo Valve Simulation and Experiment Comparison

4.2. Actuator Model

In actuator, there are two important components which must be considered. One of them is compressibility of the hydraulic fluid and the other is the inverse kinematics of the slider-crank mechanism i.e., determination of the piston position and velocity. While finding the position of the actuator, initial condition is found by the position of the barrel. Also actuator stroke length is considered. Although the piston areas are equal, the model is designed to solve any actuator which has different areas. Finally it is assumed that the stroke will never touch the cylinder wall. So the corresponding dead volume in cylinder is considered in solution.

4.3. Friction Test Results

Friction model is considered to be done separately. The frictions and the mechanical limits are considered. Unbalance effect is not included. In this example, parameters are not the same as the original system. These are just for the representation for different cases. In this model, to determine the acceleration of the barrel, the classical derivative block is not used. Instead of it, derivative is calculated by the help of the memory blocks in Simulink. Also another problem is the determining the point of zero cross of the relative velocity of the barrel. While the solution is made with fixed time steps "Zero Cross Detection" block cannot be used increment found by the derivative of the relative velocity and the time step. The sign change is detected between the relative velocities at the present and the next time step.

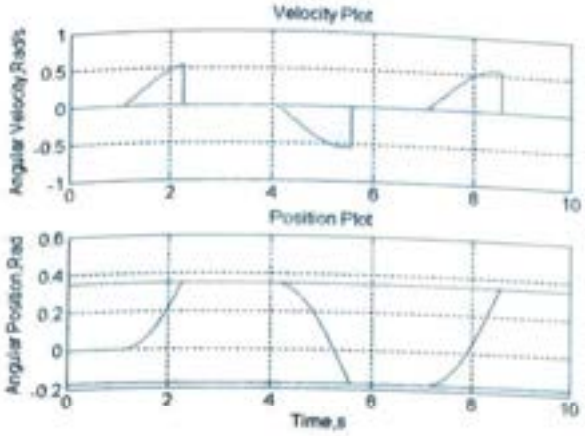

Figure 4.3 Velocity and the Position of Simplified Barrel

At first simulations, only torque was applied to the system while the disturbance is zero. Then only disturbance was applied to the system. The disturbance is an angular velocity at the joint which mounts the barrel to the hull. A series of torques and disturbances are selected to simulate. Disturbance is applied and friction is sometimes much more than the friction torque and caused the barrel rotates without touching the mechanical limits and be stuck when the friction decreases to a level less than the friction. In this situation velocity graphs have no jumps.

4.4. Barrel Model

The last component of the system is the barrel and it contains a logic block. This block checks the conditions which explained in Chapter 2 Section 4. According to the conditions, logic block decides whether the barrel moves or stops at the next time step and selects the corresponding friction torque to this motion. By controlling the relative velocity and the physical limits, it defines the stop conditions and resets the integral block after this decision. Inertial torque is taken into consideration. Disturbance originates from the road profile is also used in this part of the model. The mechanical limits which are relative to the hull are demonstrated by the limited integrals.

The position and the velocities of the barrel for two cases explained before can be seen in the figures. The deviation of the barrel position from the zero point is differing but the best ones are the cases in which the disturbance feed forwards are used. Stabilization accuracy is about $1x10^{-3}$ rad while the V=20 km/h and □d□ 0.016 rad/s and $6x10^{-4}$ while the V=40 km/h and □d□ 0.008 rad/s. The minimum stability accuracy determined in [3] with basic, second generation and director type stabilization systems is 1.0 mil, 0.5 mil and 0.2 mil respectively. While a circle is 6280 milirad or 6400 mil, stabilization accuracy of

the model will be equal to 0.1 milirad or 0.102 mil. Compare to these values, model has an accuracy same as the basic stabilization system.

4.5. System Simulation

Controller of the system consists of two PIDs. Velocity and position of the barrel are fed back. Each loop is controlled by one PID controller. In addition to this, for disturbance rejection, disturbance is fed forward to the controller.

Control strategy mentioned before is used by adding velocity feed forward to the controller. System input is a sine wave which is saturated before the peaks. Hence, the error while taking the derivatives of the command signal is prevented. Also feed forward is scaled with a gain to tune the effect of the feed forward on the command signal.

Controller parameters are tuned while a step command which does not cause the barrel hit to the hard-stops is applied to the system. Tuning process used in controller is as follows.

- Set all gains zero.
- Apply a step command.
- Raise proportional gain until the system begins overshoot.
- Raise integral gain until overshoot is approximately 15 %.
- Raise derivative gain to remove some of the overshoot

Control strategy mentioned before is used by adding velocity feed forward to the controller. System input is a sine wave which is saturated before the peaks. Hence, the error while taking the derivatives of the command signal is prevented. Also feed forward is scaled with a gain to tune the effect of the feed forward on the command signal. Control strategy mentioned before is used by adding velocity feed forward to the controller. System input is a sine wave which is saturated before the peaks. Hence, the error while taking the derivatives of the command signal is prevented. Also feed forward is scaled with a gain to tune the effect of the feed forward on the command signal.

CHAPTER 5

CONCLUSION

5.1. Summary and Conclusion

In this study, stabilization of a Main Battle Tank is considered. System elements are examined one by one and modelled in Matlab, Simulink environment. Modelling is a difficult problem itself and to be able to model the systems assumptions for undetermined facts and nonlinearities must be done. System controller, electro hydraulic servo valve, actuating system (slider-crank mechanism), barrel are elements of the Main Battle Tank system.

Control system is constructed by using PID controllers. Velocity feed forward is used to make the system more rapid. It has two PID controllers one for position loop and the other for the velocity loop. Disturbances which come from the ground via the hull were embedded to the system from the control signal to make the system more sensitive to the changes in hull motion. Stabilization, disturbance rejection, is tried to be improved by adding disturbance compensation. The transfer function between the disturbance and the output of the system is determined. Frequency response is examined and the contents of the feed forward strategy are determined.

Servo valve is a zero-lapped, classical four way valve. It has three stages. The valve is modelled as second order system. Valve dynamics are identified by the help of the actual system's step response records. Simulations and comparisons with the actual system are made with the model parameters found with identification. Nonlinearity in the servo valve is considered. Actuation system is a double-acting hydraulic cylinder coupled with a slider-crank mechanism which transforms the translational motion to the rotational. Inverse kinematics is considered in the solution while modelling. The cylinder and the pressurized lines are assumed to be absolutely rigid. Compressibility in the actuation system is considered. Piston areas are equal in the system but it is considered that they may be different for other systems while modelling.

Angular position of the barrel is the output of the system. Inertial effects, Coulomb and viscous frictions, hard-stops define the motion of the barrel. A simplified model of the

barrel is constructed to define the possible cases with the effects of inertia, friction and hard-stops. The way of effecting of disturbance caused from the road profile is as an angular velocity at the joint which mounts the barrel to the hull. The source of this velocity, acceleration and unbalance affect the barrel in vertical axis.

The measurement devices used in the actual systems are also modelled. These are LVDT in servo valve, gyroscopes on the hull and gyroscope and encoder on the barrel. LVDT is represented in the system model as a gain, gyroscope as a second order transfer function and encoder as a quantization block. Simulations are made for the stabilization system. They are made with two different constant velocities but the model can also solve the situation with variable velocities. Model which was constructed for Main Battle Tank gives the opportunity to use any of the elements included in the system without risk of hazard for machines and users separately. Also, they can be used to design the possible future systems.

The measurement devices used in the actual systems are also modelled. These are LVDT in servo valve, gyroscopes on the hull and gyroscope and encoder on the barrel. LVDT is represented in the system model as a gain, gyroscope as a second order transfer function and encoder as a quantization block. Simulations are made for the stabilization system. Model which was constructed for Main Battle Tank gives the opportunity to use any of the elements included in the system without risk of hazard for machines and users separately. Also, they can be used to design the possible future systems.

CHAPTER 6

WORK TO BE DONE IN PHASE II

System modelled in this study will be satisfactory to examine the main cases included and will be helpful for users. For future work, other probable components can be added to the model such as pipes, hydraulic fluid temperature, leakage etc.PID controllers are very common in industry. However, there is not a common method for tuning these controllers. PID controllers are dominant, effective, simple and applicable for all kinds of systems. Other controller strategies may be tried such as intelligent control, full state feedback etc.

LVDT is represented in the system model as a gain, gyroscope as a second order transfer function and encoder as a quantization block. Simulations are made for the stabilization system. They are made with two different constant velocities but the model can also solve the situation with variable velocities. Model which was constructed for Main Battle Tank gives the opportunity to use any of the elements included in the system without risk of hazard for machines and users separately.

Hull dynamics is neglected in this study and output of the hull gyro is used directly. Hull model may be constructed and actual road profiles may be used. The servo valve is identified in this study with very limited data. A better valve can be used or may be done additional tests on the valve to make a better model of the servo valve. Coulomb and viscous frictions are modelled but it is assumed that they exist only in the joint which mounts the barrel to the hull. The other mountings such as the one between the piston and the barrel and the one between the cylinder and the hull, actuation system have also frictions.

ABSTRACT

Augmented Reality (AR) is the technology that overlaps virtual objects onto the real world objects. It has three main features: the combination of the real world and the virtual world, real-time interaction, and 3D registration. It is a technology that works on computer vision based recognition algorithms to augmented sound, video, graphics and other sensor based inputs on real world objects using the camera of your device. The shortest route and graphics information in 3D are not notified in normal maps to avoid such problems we have developed a 3D virtual environment that gives graphics and contain more information about a particular place. This project is done by using "UNITY" application, the engine can be used to create three-dimensional, two-dimensional which helps to view all these graphics and routes in 3D view.

CHAPTER 1

INTRODUCTION

1.1 Introduction

Augmented reality (AR) is an interactive experience of a real-world environment where the objects that reside in the real-world are enhanced by computer-generated perceptual information, sometimes across multiple sensory modalities,

Including visual, auditory, haptic, somatosensory and olfactory. The overlaid sensory information can be constructive (i.e. additive to the natural environment), or destructive (i.e. masking of the natural environment). This experience is seamlessly interwoven with the physical world such that it is perceived as an immersive aspect of the real environment. In this way, augmented reality alters one's ongoing perception of a real-world environment, whereas virtual reality completely replaces the user's real-world environment with a simulated one. Augmented reality is related to two largely synonymous terms: mixed reality and computer-mediated reality.

The primary value of augmented reality is the manner in which components of the digital world blend into a person's perception of the real world, not as a simple display of data, but through the integration of immersive sensations, which are perceived as natural parts of an environment. The earliest functional AR systems that provided immersive mixed reality experiences for users were invented in the early 1990s, starting with the Virtual Fixtures system developed at the U.S. Air Force's Armstrong Laboratory in 1992. Commercial augmented reality experiences were first introduced in entertainment and gaming businesses. Subsequently, augmented reality applications have spanned commercial industries such as education, communications, medicine, and entertainment. In education, content may be accessed by scanning or viewing an image with a mobile device or by using marker less AR techniques. An example relevant to the construction industry is an AR helmet for construction workers which displays information about construction sites.

CHAPTER 2

LITERATURE REVIEW

2.1 Location-based services

Tom Hulme - 1559316 Department of Electrical and Computer Engineering in 2010.

2.1.1 Introduction

Due to the ever increasing popularity of mobile devices, Location-based services can be easily created and used to interact with the areas around us. Mobile devices with cameras can be used to navigate through areas using virtual or augmented reality; where an image is captured through the camera, and then overlaid with information to help a user navigate. Being that this field of user interaction is fairly new, this paper reviews three existing research papers in their exploration of the area, and how mobile devices can be used to recognize the world around abuser and change how they interact it. The papers cover the use of a mobile device's camera, wireless, and GPS systems to approximate the user's location, and provide feedback through Augmented and Virtual Reality methods.

2.1.2 Objective

This paper looks into the ways in which Location-Based Services are able to change the way we interact with the world around us. Using Augmented and Virtual Reality, and combining them with the camera, Wireless, and GPS systems in mobile devices; or combining them with external devices, we are able to create navigation systems to assist users in finding their way around both indoor and outdoor settings.

2.1.3 Technology

Indoor Navigation the idea of navigating through indoors paces with mobile devices is not a new one, but constant advancements in both the technological capabilities and availability of the eMobile devices has meant the ability to easily set up systems to navigate indoors is much easier. In later sections we will cover how indoor navigation is accomplished. Outdoor Navigation Navigation with the use of maps has existed for thousands of years, but with mobile devices users are now able to find their way through technological means such as GPS. Location

CHAPTER 2

LITERATURE REVIEW

2.1 Location-based services

Tom Hulme - 1559316 Department of Electrical and Computer Engineering in 2010.

2.1.1 Introduction

Due to the ever increasing popularity of mobile devices, Location-based services can be easily created and used to interact with the areas around us. Mobile devices with cameras can be used to navigate through areas using virtual or augmented reality; where an image is captured through the camera, and then overlaid with information to help a user navigate. Being that this field of user interaction is fairly new, this paper reviews three existing research papers in their exploration of the area, and how mobile devices can be used to recognize the world around abuser and change how they interact it. The papers cover the use of a mobile device's camera, wireless, and GPS systems to approximate the user's location, and provide feedback through Augmented and Virtual Reality methods.

2.1.2 Objective

This paper looks into the ways in which Location-Based Services are able to change the way we interact with the world around us. Using Augmented and Virtual Reality, and combining them with the camera, Wireless, and GPS systems in mobile devices; or combining them with external devices, we are able to create navigation systems to assist users in finding their way around both indoor and outdoor settings.

2.1.3 Technology

Indoor Navigation the idea of navigating through indoors paces with mobile devices is not a new one, but constant advancements in both the technological capabilities and availability of the eMobile devices has meant the ability to easily set up systems to navigate indoors is much easier. In later sections we will cover how indoor navigation is accomplished. Outdoor Navigation Navigation with the use of maps has existed for thousands of years, but with mobile devices users are now able to find their way through technological means such as GPS. Location

Based Services are able to build upon this foundation to provide more extensive assistance in the area of outdoor navigation.

2.1.4 Result

The paper a mobile indoor navigation system interface adapted to vision-based localization, explained how Moller et al. were able to approximate a user's location then provide them with a functional navigation service. The authors used the mobile device's camera exclusively, approximating the location with visual localization, and applied an Augmented or Virtual Reality overlay to provide information to the user.

2.1.5 Conclusion

There are a number of different applications for Location Based Services, as well as a number of different methods to provide them. If we are to use Augmented Reality, we need to be sure that we correctly and reliably get the direction a user is facing, as an incorrect heading has more of a negative impact on usability. The camera on a mobile device, coupled with Wi-Fi and GPS positioning seems to be most accurate when approximating a user's location, and may even be coupled with Google Street View, or additional external devices. These methods can be used to provide users with a new way to interact with the world around them, and allow anybody to easily navigate unfamiliar territory.

2.1.6 Drawbacks

Position of the object decides the output.

Lack of privacy.

Expensive to develop and maintain.

2.2 Review and analysis of augmented reality

Sara Rankohi & Lloyd Waugh, Visualization Engineering in 2013.

2.2.1 Introduction

The complex nature of the architecture, engineering, construction, and facility management (AEC/FM) industry and its high demand for access to information for evaluation, communication and collaboration, increases the industry's need for information

2.2 Review and analysis of augmented reality

Sara Rankohi & Lloyd Waugh, Visualization Engineering in 2013.

2.2.1 Introduction

The complex nature of the architecture, engineering, construction, and facility management (AEC/FM) industry and its high demand for access to information for evaluation, communication and collaboration, increases the industry's need for information

technologies. Recent visualization technologies such as virtual and augmented reality technologies are ideal in this environment.

2.2.2Objective

Augmented reality gives a view of the real world where elements are superimposed by computer generated files such as graphics, sounds, videos, or digital information.

2.2.3 Technology

Augmented reality technology, which typically layers virtual information on a real scene, utilizes different hardware (personal computers (PC), laptops, head mounted displays (HMD), GPS, data gloves, smart boards, etc.) and software (AutoCAD, Photoshop, AC3D, 3D Studio, building information model (BIM), etc.). From a technology perspective articles are classified into three categories: (1) user experience: (a) immersive or (b) non-immersive, i.e., desktop-based; (2) device: (a) mobile, (b) stationary or non-mobile; (3) delivery: (a) web-based, (b) standalone.

Devices such as HMD and data-gloves create immersive AR systems, in which users feel immersed in a virtual environment just as they usually feel in a real environment. Due to the improving performance of handheld devices and recent solutions to technical difficulties such as tracking, there is an opportunity for augmented reality systems to become portable, as well there is a growing interest in the use of mobile AR applications. Web-based augmented reality technologies can deliver project information to remote locations and are very useful to manage virtual projects around the globe. Finally, due to the wide range of AR applications, these technologies can be used both on-site for progress monitoring and in an office (not-on-site) for design control. From the user experience perspective, 32 articles have a principal focus on immersive AR technologies, 76 articles (57%) have a principal focus on non-immersive or desktop-based AR technologies, while 25 articles were not applicable. The number of articles with immersive and non-immersive technologies as a principal focus by year.

2.2.4 Result

AR technologies provide proven benefits especially in the areas of visualization simulation and communication/collaboration, however these benefits are not yet widely adopted by AEC industry participants nor have they been incorporated into industry-wide workflow processes. As a result, industry participants choose to pilot (i.e., system development

and application) AR technologies on a few projects rather than adopting or piloting the technology across their organization.

2.2.5 Conclusion

A structured methodology was used to identify 133 articles on the topic of augmented reality from eight prominent AEC industry journals. The first article was published in 1999; a significant increase in the number of articles on this topic occurred during the year 2008. In addition to statistics on the counts of articles by year and the first author's country of residence, ten interpreted dimensions were developed for classification of these articles. Literature show field workers and project managers have high interests in using non-immersive and desk-top standalone (individual) AR technologies during construction phase of a project to compare as-planned versus as-built statuses to monitor progress and defect detection. Whereas, it is predicted that future trend, is more toward using collaborative and internet based mobile AR systems which have applications not only in construction phase, but also in procurement and maintenance phases of a project. Due to various benefits of AR technology for construction industry, the application of AR systems for initiation and procurement phase of a project to compare model vs. model and reality vs. reality is recommended. Moreover, lightweight mobile and immersive AR systems are also recommended for field personnel due to dynamic environment of construction fields.

2.3 Augmented reality tracking techniques

IOSR Journal of Computer Engineering (IOSRJCE) Ihsan Rabbi ,Sehat UllahS,iffat Ullah Khan (July-Aug. 2012)

2.3.1 Introduction

Augmented Reality (AR) is a technology through which the view of real world environment is augmented by computer generated elements/objects. AR is related to a mediated reality, in which a view of reality is modified using a computer system. By contrast, virtual reality replaces the real world with a simulated one. In the Reality-Virtuality Continuum by Milgram et al (1994), augmented reality lies between the virtual world and real world.

This paper describes the systematic literature review (SLR) protocol which will be used to explore the challenges during tracking objects in the augmented reality system, the proposed solutions presented and their limitations. The goal of our research is to gain in depth understanding of challenges that faced during augmented reality tracking. Tracking and registration are the most critical issues for AR applications. The proper alignment of virtual objects to the real world environment is called registration.

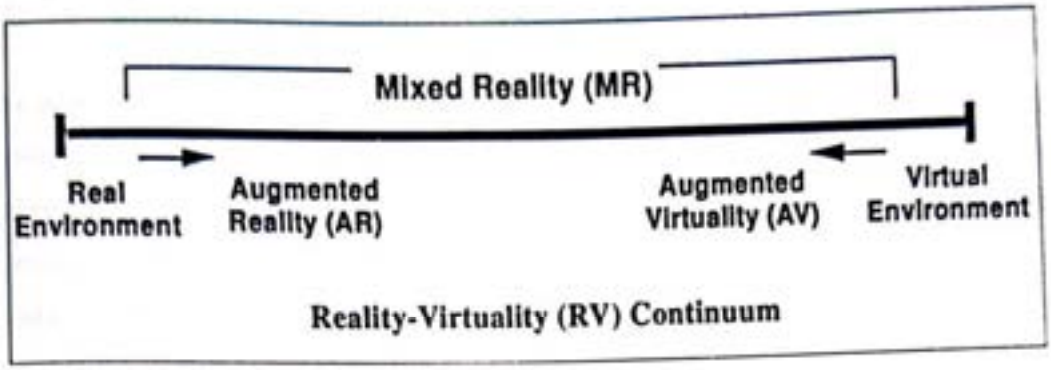

Figure 2.1 Simplified Representation of a Reality Virtuality Continuum

Tracking is the main issue for outdoor augmented reality applications. Calibration is another challenge for augmented reality system. Interaction Techniques and User Interfaces are problems for AR system that need to be addressed. Portability of AR system is also a challenge as a wearable system needs to be carried out a whole set of heavy equipment for a long time. The virtual objects and real world environment are required to be of same Illumination. Another issue is occlusion, that is a process to determine which surface or its parts are not visible from a certain view-point.

2.3.2 Objective

This research paper aims to perform a Systematic Literature Review (SLR) for the identification of challenges during tracking an object in augmented reality environment and how these challenges can be overcame.

2.3.3 Technology

STEP-A Use the Research Questions for the derivation of major terms, by identifying population, intervention and outcome.

STEP-B For these major terms, find the alternative spellings and synonyms.

STEP-C Verify the key words in any relevant paper.

STEP-D Use of Boolean Operators for conjunction if the database allows, in such a way, to use 'OR' operator for the concatenation of alternative spellings and synonyms whereas 'AND' for the concatenation of major terms.

2.3.4 Result

The expected outcomes of the review will be the identification of a list of challenges and its proposed solutions while tacking objects in augmented reality environment.

2.3.5 Conclusion

Tracking and registration are the most important issues for AR applications that need to be properly addressed. Various studies have shed light on the augmented reality tracking process. However, so far, no systematic literature review process has been conducted for the identification of challenges and limitations for augmented reality tracking process. We presented our study plan in the form of the SLR protocol. We have developed the SLR protocol and currently we are in the process of its implementation. The findings of this research will provide the challenges and limitations in augmented reality tracking techniques, which will be then addressed to provide a complete solution for tracking objects in augmented reality system.

2.3.6 Drawbacks

Privacy is loss.

High cost to implementation.

2.4 Navigation in augmented reality

Bivas Biswas, published by vocational education and training school in 2014, Retrieved September 2016

2.4.1 Introduction

A lot of the technology that we see today as normal has come from science fiction. Mobile handheld devices, such as smartphones and tablets, is one of those things that we use today in our everyday life that people only imagined before. Being able to see an edited world where the real and the virtual blends is another one of those ideas that has flourished in science fiction. Today it is real and it is called augmented reality

Augmented reality (AR) is described as a view of the real world modified by a computer. It is a subset of virtual reality (VR), but differs in the way that AR brings the virtual into the real world whilst VR substitutes it. This distinction between AR and VR gives the users

different experiences, whereas AR offers the user a greater sense of realism than VR does. The concept of augmented reality was first pioneered by Ivan Sutherland (1968), who developed a head-mounted 3D display, but the term was not coined until 1992 by Thomas Caudell and David Mizell (Caudell and Mizell, 1992).

Figure 2.2 The swords of Damocles

Even though the technology has been around for more than two decades it is still not out of its infancy. The Gartner's Hype cycle is a methodology which helps enterprises to decide on innovation investments by showing how mature technologies are (Gartner, 2014). As can be seen, augmented reality has passed its initial hype and is now in the state of maturing into a lasting technology. When a technology is in this state, only successful technologies will start to climb towards and finally emerge into the plateau of productivity. According to the cycle, AR is estimated to reach the plateau of productivity within five to ten years. There are a lot of possibilities offered by the AR technology that is being developed. The areas of use stretches from industry and military to medical use and computer games. The development and spread of smart phones and small handheld devices is continuously increasing and the research on AR technology have had to adapt and increase with it (Azuma et al., 2001). As with a lot of research in the area of computer science, and which has been pointed out by many usability researchers, most of the research done on AR is technology driven and the user experience tend to come in second place if considered at all (Ko et al., 2013).

2.4.2 Objective

An AR prototype was developed and tested against a standard map, in the form of Google Maps, both used on a smart phone. The experiments were performed using think aloud during the tests and questionnaires before and after to collect both quantitative and qualitative

data. The experiment was performed using possible users of AR as test subjects. The results were very similar for both applications but in favor of Google Maps.

2.4.3 Technology

By gathering user information, tests, as well as a post-test questionnaire a lot of different data were gathered to accommodate all the usability metrics needing an answer. Since the type of test were chosen at an early stage the findings from the literature study helped in choosing the SDK to use in making the prototype. By using a finished SDK the limitations on graphics and functionality, such as accurate GPS position, were already in place and the prototype had to be created around those limitations. When users became uncertain if they were doing the task right they would turn to me as a moderator for answers, which could influence the results. One potential problem that was identified before the tests through the survey study was that all the test subjects were already familiar with the Google maps application. This removed the learning factor for the application and might have had an unfair impact on the results.

2.4.4 Result

The most important results from the test sessions, both problems and benefits. Among these are the question on whether or not it is more useable with augmented reality, the lack of GPS accuracy and the choice of method and setting.

2.4.5 Conclusion

In this thesis an AR prototype was developed for navigational purposes and tested against Google Maps in an experimental study with the focus on the usability requirements learnability, When the prototype was evaluated the results showed that for navigation when walking, Google Maps might be more suitable as the world looks today with the technology at hand but for navigation when driving, an AR application will probably benefit the driver more than using a standardized map application such as Google Maps. When looking at the separate usability requirements the prototype performed as expected on learnability, whilst the usability requirement was negligible for Google Maps since all the test subjects had already used it. There were negligible differences in efficiency, there were some differences in effectivity that favoured Google Maps and lastly, Google Maps performed better in user satisfaction. Even though the prototype did not perform as well as hypothesized based on the literature review, the test gave indication on that there is a lot of future work that can be done in this field and

that the concept of augmented reality is highly current in the strive of bringing the virtual into our lives and in the concept of the technology adapting to the user and not the other way around.

2.4.6 Drawbacks

It lack of GPS accuracy and the choice of method and setting.

Query is not useable with augmented reality & Maintenance is low.

2.5 Indoor navigation using augmented reality

Nahush Narendra Bhanage Electrical Engineering and Computer Sciences University of California, Berkeley May 2014

2.5.1 Introduction

Indoor Positioning refers to locating objects or spaces inside a building. Global Positioning System (GPS) does not work accurately indoors due to signal attenuation and reflection caused by roofs and walls. Hence in most situations, GPS based location tracking does not produce useful results. As a result, most of the popular indoor positioning systems work on technologies such as Wi-Fi, Bluetooth, Radio beacons which are more accurate than GPS. Furthermore, accurate location determination of indoor spaces could have numerous interesting applications if integrated with augmented reality. Indoor navigation systems have started incorporating augmented reality techniques to visually help the user in navigating indoors. User experience is critical in indoor navigation systems. Maps can only be useful in tracking the location of a person or object whereas with augmented reality, a lot of relevant information can be displayed along with the location information.

There is a strong untapped potential in augmented reality techniques, with respect to indoor navigation. This is possible if his relative location in the museum is known. In this paper, we demonstrate how augmented reality can enhance the utility of indoor positioning systems. The Literature Review section gives an overview of the various technologies used in indoor positioning systems and the existing landscape (key players) in this market. It is followed by the Methodology section, which describes how we targeted a specific user scenario and the technologies we used to develop an augmented reality based prototype. We then discuss the user study results in the Results section. Finally, the Conclusion section summarizes the paper and briefly discusses possible future work in this area.

2.5.2 Objective

Indoor positioning systems help in the localization of objects or spaces inside a building, where Global Positioning System (GPS) and cellular network don't work effectively. It also describes our application development process, right from target user interviews to an interactive high-fidelity prototype development in Android. Localization is achieved by creating a location API simulator and using the orientation sensors in the phone/tablet.

2.5.3 Technology

We decided to develop an Android application (Augmented Lab) to demonstrate the usefulness of combining augmented reality with indoor positioning. We needed access to an existing indoor positioning API to accurately determine the smartphone's location and a 2D map of the indoor space.

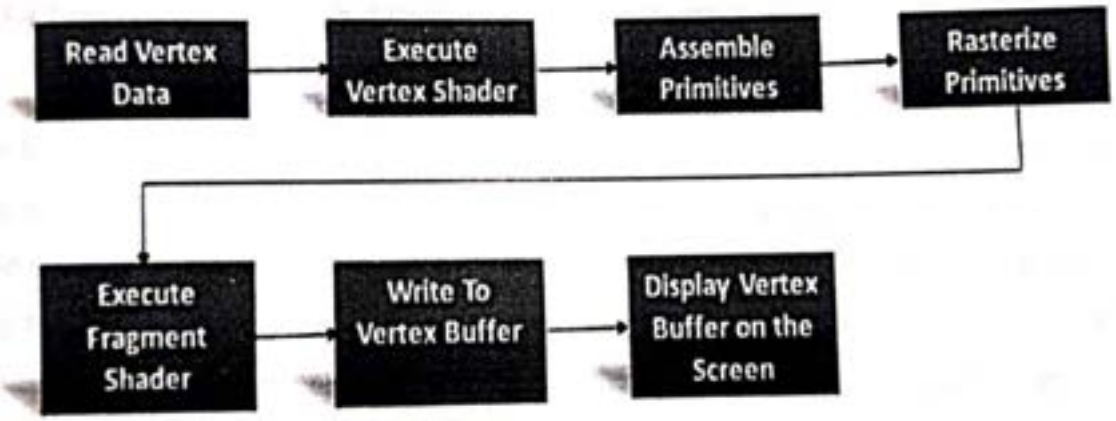

Figure 2.3 Block for navigation system

As such, our application could accommodate any in door position our industrial sponsor was Qualcomm Research Silicon Valley and we started working on this project hoping to use their indoor positioning platform.

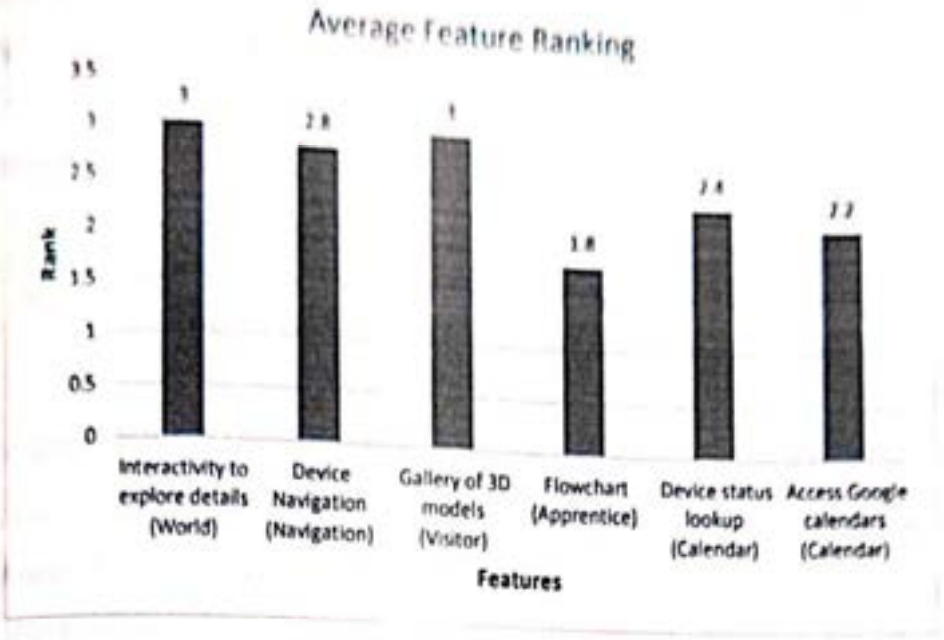

Figure 2.4 Average feature ranking

2.5.4 Result

We conducted another user study, this time for our interactive prototype. Ten users in the CITRIS Invention lab, UC Berkeley were randomly selected. The study was conducted on the affine 3D printer in the lab. The sample set consisted of lab administrators, undergraduate and graduate students who had some experience of working on Affine. They were asked to try out the different functionalities in our application and then answer some questions related to usability. The users were also asked if they would prefer using our application instead of the traditional instructions in the form of documents. As we can see from 80% of the users preferred using our application. The remaining 20% preferred documented instructions since they did not find our 'Apprentice' mode detailed enough. They suggested adding links to videos explaining how to use the tools.

2.5.5 Conclusion

Future work could include replacing our simulated location API with Qualcomm's indoor positioning system (IZat). At this point, localization in our approach is entirely based on the location API and orientation sensor readings. Integrating object detection in the current approach would make the localization extremely robust, giving an inch-level accuracy. As of now, once the device is detected (based on location and orientation) the 'Apprentice' mode

At this point, localization in our approach is entirely based on the location API and orientation sensor readings. Integrating object detection in the current approach would make the localization extremely robust, giving an inch-level accuracy. As of now, once the device is detected (based on location and orientation) the 'Apprentice' mode

shows static images that explains how to use that device. If we are able to implement a highly accurate object detection algorithm, then we can get rid of the static images in 'Apprentice' mode and render text and 3D arrows accurately pointing to different parts of the device.

2.5.6 Drawbacks

Finding the right provider and Maintenance is low.

No proper indoor positioning

2.6 Navigation Systems for Fastest Routes

International Journal of Pure and Applied Mathematics Special Issue , Varshit Ratna , Krishna Chythanya August 16, 2018

2.6.1 Introduction

Mobility is very important in our society. People live in one city and work in another. They go to visit friends and family living in different parts of the country. Even leisure time is not always spent in their residence. Despite the Dutch government's efforts to increase the use of public transportation, the car is still the most widely used means of transportation. Every time someone travels from one location to another (by car), he or she first determines the best route to reach the destination. Depending on the time of day and the day of the week, this route may be different. For example, the driver may know that a certain road is always congested at a particular time and day. As a consequence, he chooses to use a different route to avoid this congestion. Car navigation systems are being offered as a special feature of new cars of an increasing number of car-brands. These car navigation systems are capable of taking over some of the tasks that are performed by the driver such as reading the map and determining the best route to the destination. They should also take daily congestion patterns into account. Because a car navigation system uses a built-in computer to determine a route, it can compare many different routes and the user expects the system to determine the best possible, or optimum route fast. This thesis is concerned with route planning algorithms that enable a car navigation system to plan optimum routes on very large real-world road networks in very little time, taking daily congestion patterns into account.

2.6.2 Objective

This paper presents a route navigation system with a new revised shortest path routing algorithm for solving road traffic problems. The system can avoid selecting no left (right) turns, one-way roads, and congested roads when it determines the shortest paths from source to destination. Also, the new revised routing algorithm is compared numerically with existing algorithms such as the Dijkstra algorithm and the algorithm. We choose a road network containing 4000 nodes which have 200 no left turn situations and find in particular that the road traffic problem of a 4000-node traffic network can be solved within only 0.651 seconds on average. The prototype system was built and some extra functions were added so that its benefits not only offer the shortest path but also provide information and security services for drivers.

2.6.3 Technology

Car Navigation Systems Currently, an increasing number of consumers has gained interest in car navigation equipment. Car navigation is no longer a luxury that is only for the rich. A car navigation system is offered as one of the many extras or as an advertising stunt of more and more "middle-class" cars. In the future, car navigation equipment may become as normal as air-conditioning. Of course, also other vehicles can use car navigation, such as trucks, busses and motorcycles. A navigation system offers the driver the possibility to be guided to his destination, by means of spoken and/or visual advices. In order to achieve this, the driver first has to enter his destination into the system. Such a destination may be a city centre, an entire street, or an address including a house number.

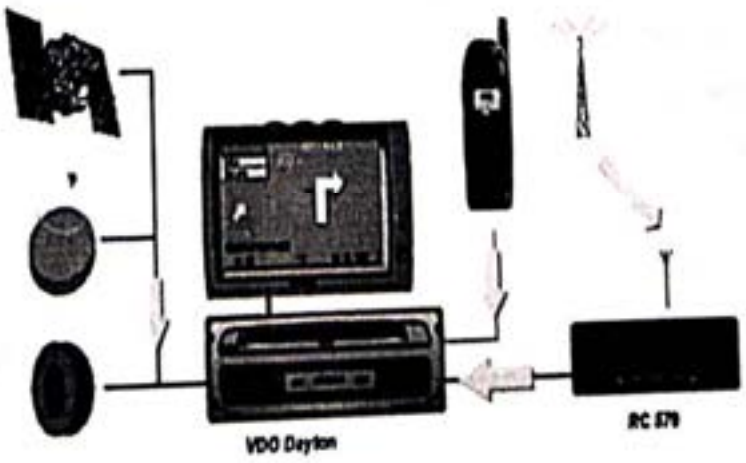

Figure 2.5 Working function of car navigation

The computer, which contains the CD or DVD player, and the screen for displaying the map and visual advice are shown in the middle. On the right, a GSM connection and TMC-RDS broadcasts used for receiving traffic information. . Information on every possible destination is contained in a database that is stored on a CD or DVD that has to be inserted into the car navigation system. Also data from external providers about interesting places such as hotels and restaurants for example is stored on the CD or DVD. The driver can ask for a list of all hotels in a certain area for example.

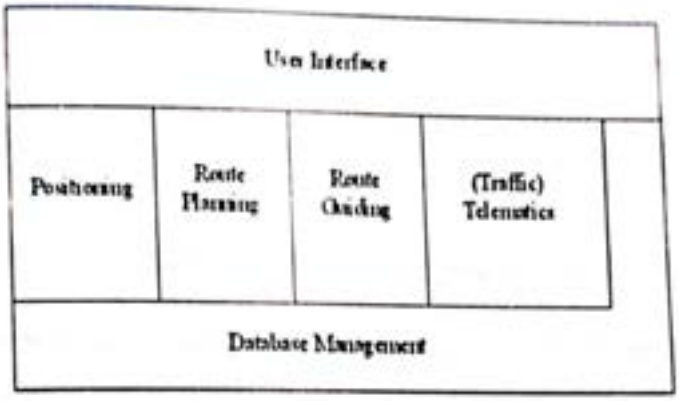

Figure 2.6 Block for navigation

First, we explain positioning. In order to determine the current location of the car on the road network, a car navigation system tries to determine the geographical position of the car. This is done by "dead reckoning" [Zhao, 1997], which is the calculation of the geographical position based on calibrated sensor information. In particular the driven distance from the tacho and the angular rate from the gyro are used to determine the position of the car. This position can be improved by using the GPS position and speed. Subsequently, this geographical position is matched to the available road network. This is done by computing the likelihood that the car is currently at a particular position on a certain road segment. The route presented to the driver is also used in this map matching process. A position on the current route is given a higher preference than other positions. If no position on the road network has a sufficiently high likelihood, the car is not positioned on any of the road segments of the road network, i.e. the car is "off map".

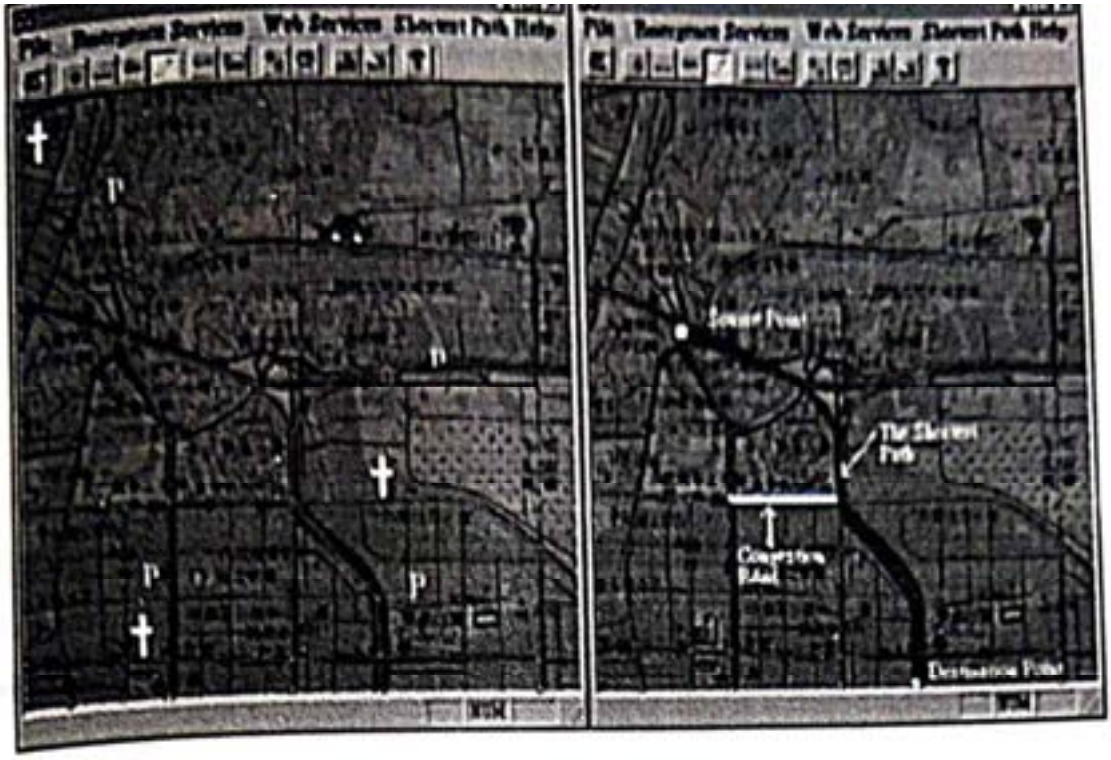

Figure 2.7 Determining fastest routing

Once the position of the car has been determined, a route can be planned from that car position to the destination. This route is planned using the available road network that is stored on a CD or DVD. The algorithm used for planning a route is (generally) based on Dijkstra's single source shortest path algorithm. To be able to determine a route fast, several approximations are used. For example, if the car position and destination are located sufficiently far apart, only important roads are used to determine the major part of the route. Furthermore, estimations of the remaining distance to the destination are used to speed up the planning process.

To calculate the efficiency of the new algorithm, we have implemented a Route Navigation System (RNS). The system was built by using the new revised routing algorithm. The RNS is developed on a PC-based portable computer. The speed of the Centre Process Unit is Pentium 1.7GHz. The size of its main memory is 256M RAM. Through a communication PCMCIA card, the application system is able to connect a server via the Internet and get some vital guidance information, for instance, the number of parking spaces in a parking lot, the number of beds in a hotel, etc. Meanwhile, a wireless Global Positioning System (GPS) receiver is installed on the system. Therefore, the RNS not only can provide the position of the car but also suggest the shortest path from source to destination. The system also can avoid congestion if some roads have heavy traffic because of accidents, rush hour, or road construction. Basically,

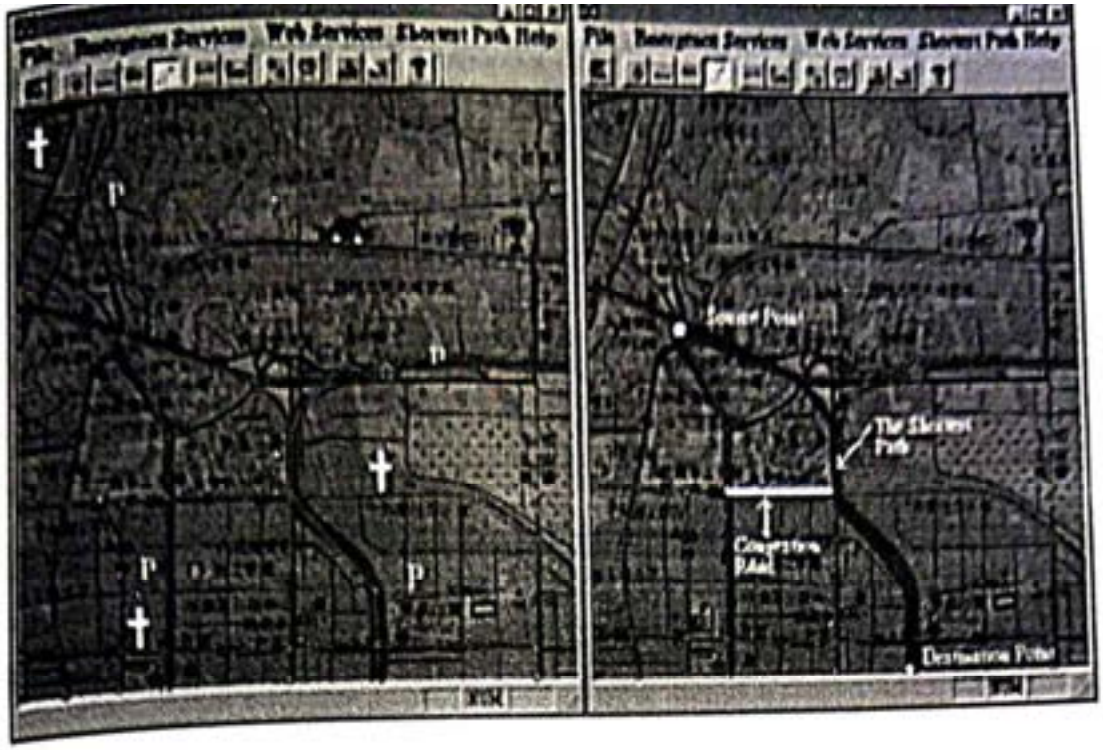

Figure 2.7 Determining fastest routing

Once the position of the car has been determined, a route can be planned from that car position to the destination. This route is planned using the available road network that is stored on a CD or DVD. The algorithm used for planning a route is (generally) based on Dijkstra's single source shortest path algorithm. To be able to determine a route fast, several approximations are used. For example, if the car position and destination are located sufficiently far apart, only important roads are used to determine the major part of the route. Furthermore, estimations of the remaining distance to the destination are used to speed up the planning process.

To calculate the efficiency of the new algorithm, we have implemented a Route Navigation System (RNS). The system was built by using the new revised routing algorithm. The RNS is developed on a PC-based portable computer. The speed of the Centre Process Unit is Pentium 1.7GHz. The size of its main memory is 256M RAM. Through a communication PCMCIA card, the application system is able to connect a server via the Internet and get some vital guidance information, for instance, the number of parking spaces in a parking lot, the number of beds in a hotel, etc. Meanwhile, a wireless Global Positioning System (GPS) receiver is installed on the system. Therefore, the RNS not only can provide the position of the car but also suggest the shortest path from source to destination. The system also can avoid congestion if some roads have heavy traffic because of accidents, rush hour, or road construction. Basically,

in the experiment of performance evaluation, we adopt 4 kinds of algorithms (i.e., Dijkstra's algorithm, Dijkstra's algorithm, the algorithm, and the revised routing algorithm (i.e., Wen-Hsu's algorithm).

2.6.4 Result

Although this paper designs and analyses the RNS, there are still several aspects where we can further improve its functions. In particular, we can extend its functions to assist the RNS to have an automatic reasoning mechanism using a knowledge-based inference engine. In addition, the method of artificial neural networks for searching the best routes of which we had used in the past can also be added for helping make decisions. So, knowing how to build an efficient searching and learning mechanism for the RNS will be also a major research issue in the future.

2.6.5 Conclusion

This paper proposed a route navigation system with a new modified algorithm for solving the no left (right) turns, one-way roads, and congestion problems on road networks. For evaluating its performance, a prototype system, Route Navigation System (RNS), was built. The system physically proves the efficiency of the system architecture. In terms of the final results of the performance analysis, the system not only provides a good solution for solving road congestion problems but also responses much faster. We strongly believe the system with the new revised routing algorithm will play an important role in traffic navigation systems for users' guidance on road networks.

2.7 Navigation in Augmented Reality from Google Maps

IEEE Transactions on Human-Machine Systems PP(99):1-12 · November 2016 with 727 Reads DOI: 10.1109/THMS.2016.2620106

2.7.1 Introduction

Google Maps and Google Earth have had an enormous impact on the way people think, learn, and work with geographic information. With easy access to spatial and cultural

information, Google Maps/Earth has provided users with the means to understand their world and their communities of interest. Moreover, the customizable map features and dynamic presentation tools found in Google Maps and Google Earth make each one an attractive option for someone wanting to teach geographic information or make customized maps. For academic researchers, Google Mapping applications are also appealing for their powerful ability to share and host projects, create customized KML (Keyhole Mark-up Language) files, and to easily communicate their own research findings in a geographic context. Recognizing their potential for revitalizing map collections and geographic education, the authors felt that many academic libraries were also going to be active in using Google Maps/Earth for a variety of purposes, from promoting their services to developing their own Google KML files for users. With Google Earth's ease of use and visualization capabilities, it was even thought that academic libraries would be using Google Earth heavily in instruction classes bringing geographic information to subject areas traditionally outside of geography.

The authors were interested in discovering how popular the Google mapping products are in the academic library setting. A survey was conducted to establish the mapping products' popularity, and type of use in an academic library setting. Results show that over 90 percent of the respondents use Google Earth and Google Maps either to help answer research questions, to create and access finding aids, for instructional purposes or for promotion and marketing. The authors recommend expanding the mapping products' user base to include all reference and liaison librarians.

2.7.2 Objective

Despite the ubiquity of Google for information searching, there was a surprising paucity of literature that documents the impact of Google Maps/Earth in academic libraries. Nevertheless, there are some articles which indicate just how much Google Maps can help raise the profile of library services. Terry Ballard, a librarian at Quinnipiac University, describes in a few articles how he and colleagues were able to use Google Earth place marks to promote his library's special collections.1 The potential for "Discovering the Library with Google Earth" is also a theme in an article by Brenner and Klein in which the Portland State University Library linked their urban planning documents collection to Google Earth for ease of searching.2 Although the focus is on public libraries, Michael Vandenberg documents how his library system began "using Google Maps as an interface for the library catalogue."

2.7.3 Technology

The first couple questions dealt with the department or area of the library in which the respondent worked in, and what their position encompassed. As expected, a large majority of respondents, 81 percent, worked in "Map/GIS Services" while 28.8 percent also had "General Reference" responsibilities. Other Library Service areas mentioned included "Data Services" and "IT," as well as some that fell outside library boundaries where staff worked in Geography and Environment Science Departments. Not surprisingly, 52 percent of the responses indicated that their position was "librarian," with the majority being "GIS librarian" or "map librarian." Others included "reference & instructional services librarian" and "science librarian." Also received were 17 responses from GIS specialists, library technicians and map assistants. What was especially noteworthy was that 12 responses were from library administrators, directors, or department heads who were finding time to work with Google Earth as part of their responsibilities. This number also included GIS coordinators and map curators responsible for making decisions in their departments.

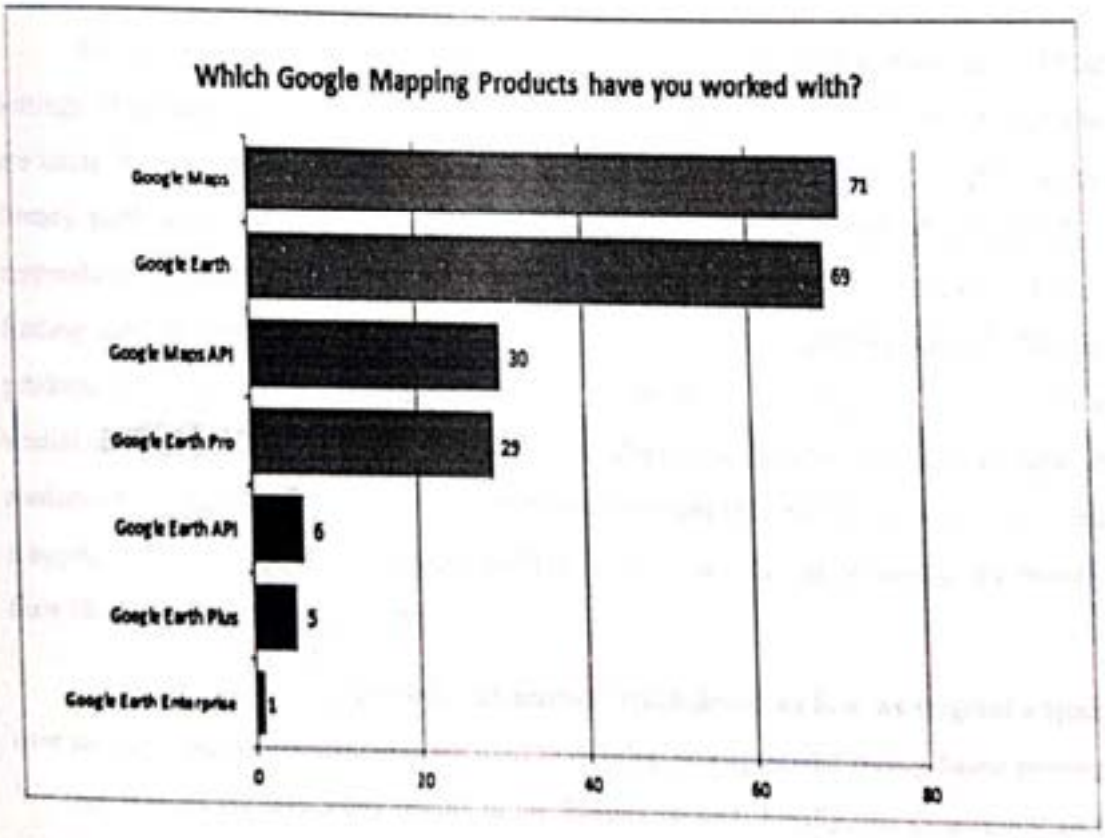

Figure 2.8 Respondents' Use of Google Mapping Products

In the last few years, KML files have become one of the more popular ways to display and distribute geographic information online. With its ease of use, and access, KML files have considerably broadened the user base of geographic information. KML files can be easily created in Google Earth, and they can be easily converted from GIS files in specialized programs. It is this ease of access and usability that has popularized geographic information, hence increasing exposure to library collections and services. This survey was therefore interested in determining how libraries are using and creating KML files.

2.7.4 Result

Although Google Maps and Google Earth are perhaps the most well-known online mapping tools available, the authors were also interested to learn if there were other products that libraries were using as part of their service offerings. As expected many mentioned Esri's ArcGIS online and Esri's Arc Explorer, while other responses included Bing Maps, Open Street Map, and Open Layers.

2.7.5 Conclusion

Google mapping applications are clearly being used for academic purposes in library settings. With such diverse capabilities made available in these programs, library professionals are using them in several different ways. Google Earth and Google Maps are popular among library staff who work with GIS and/or map collections. In fact, over 90 percent of the respondents use both products, either to help answer research questions, to create and access finding aids, for instructional purposes or for promotion and marketing. Google Mapping products have also helped libraries revitalize their collections as well as assist in transferring spatial information literacy skills to academic students and faculty. The authors hope that readers who work in a Map/GIS library setting will be inspired by the many examples of online mapping projects outlined in this paper and they will too use the online tools to the benefit of their library and their library users.

It is followed by the Methodology section, which describes how we targeted a specific user scenario and the technologies we used to develop an augmented reality based prototype. We then discuss the user study results in the Results section. Finally, the Conclusion section summarizes the paper and briefly discusses possible future work in this area. Google mapping products offer libraries an online platform to share information, and resources in an easy, accessible and low-cost way.

2.7.6 Drawbacks

It requires high-powered mobile devices.

Maintenance is low.

CHAPTER 3

THEORETICAL BACKGROUND

3.1 Abstract

This project is based on augmented reality, a method which is better than any other maps. When compared to other maps, it gives graphics and contains more information about a particular place. This application requires a mobile camera and when we scan the name board of the particular area, it gives immediate information about that place. This project is done by using "UNITY" application.

3.2 Introduction

Augmented Reality (AR) is a new technology that involves the overlay of computer graphics on the real world. One of the best overviews of the technology is, that defined the field, described many problems, and summarized the developments up to that point. That paper provides a starting point for anyone interested in researching or using Augmented Reality.AR is within a more general context termed Mixed Reality, which refers to a multi-axis spectrum of areas that cover Virtual Reality (VR), AR, telepresence, and other related technologies. Virtual Reality is a term used for computer-generated 3D environments that allow the user to enter and interact with synthetic environments. The users are able to "immerse" themselves to varying degrees in the computers artificial world which may either be a simulation of some form of reality or the simulation of a complex phenomenon .AR example with virtual chairs and a virtual lamp. In telepresence, the fundamental purpose is to extend operator's sensory-motor facilities and problem solving abilities to a remote environment. In this sense, telepresence can be defined as a human/machine system in which the human operator receives sufficient information about the tele operator and the task environment, displayed in a sufficiently natural way, that the operator feels physically present at the remote site. Very similar to virtual reality, in which we aim to achieve the illusion of presence within a computer simulation, telepresence aims to achieve the illusion of presence at a remote location. AR can be considered a technology between VR and telepresence. While in VR the environment is completely synthetic and in telepresence it is completely real, in

AR the use sees the real world augmented with virtual objects. When designing an AR system, three aspects must be in mind: Combination of real and virtual worlds; Interactivity in real time; Registration in 3D.Wearable devices, like Head-Mounted-Displays (HMD), could be used to show the augmented scene, but other technologies are also available .Besides the mentioned three aspects, another one could be incorporated: Portability. In almost all virtual environment systems, the user is not allowed to go around much due to devices limitations. However, some AR applications will need that the user really walks through a large environment. Thus, portability becomes an important issue.

3.3 Materials and Methods

3.3.1 Depth Matching for Targeting

We determined a task for evaluation of BARS that was appropriate for operational use by dismounted warfighters. For BARS-ET, however, we need a slightly different task. The task for BARS was to judge depth of occluded objects through virtual representations. This is a physically unrealistic scenario, which is inappropriate for training. For BARS-ET, we need to modify the task to test perception of depth of virtual representations of objects that would be physically visible if they were real. This is important because an envisioned task for BARS-ET users is that of a forward observer, who call coordinates for indirect fire on a target. The forward observer thus maintains line-of sight contact with the target, and determines the direction and distance from his location to the target. Results from our pilot test that users were reasonably accurate at matching distances, but got poorer with increasing distance to the real object. One training scenario has the forward observer look at a miniature world of about 60 m; our hallway scene measured about 45 m to the most distant referent, with referents roughly equip-spaced along the usable length of the hallway. Four users (normal or corrected-to-normal) manipulated the virtual target's depth in the hallway with a trackball that was restricted to one degree of freedom in software. Linear perspective, provided by the walls and apparent size of the referents and virtual target, was the most powerful depth cue available. The virtual target also became more transparent as the user moved it further away ($\alpha \in [0.7, 0.3]$, near too far). The next step for this particular task is to design a study that can measure the effectiveness of the training with the virtual targets. As noted, virtual targets enable capabilities that are difficult to attain with current targets, such as mobility and variety of scenarios.

But because the nature of the depth perception task is not yet fully understood, we investigate the perceptual effects of this type of training.

3.4 Working model for AR

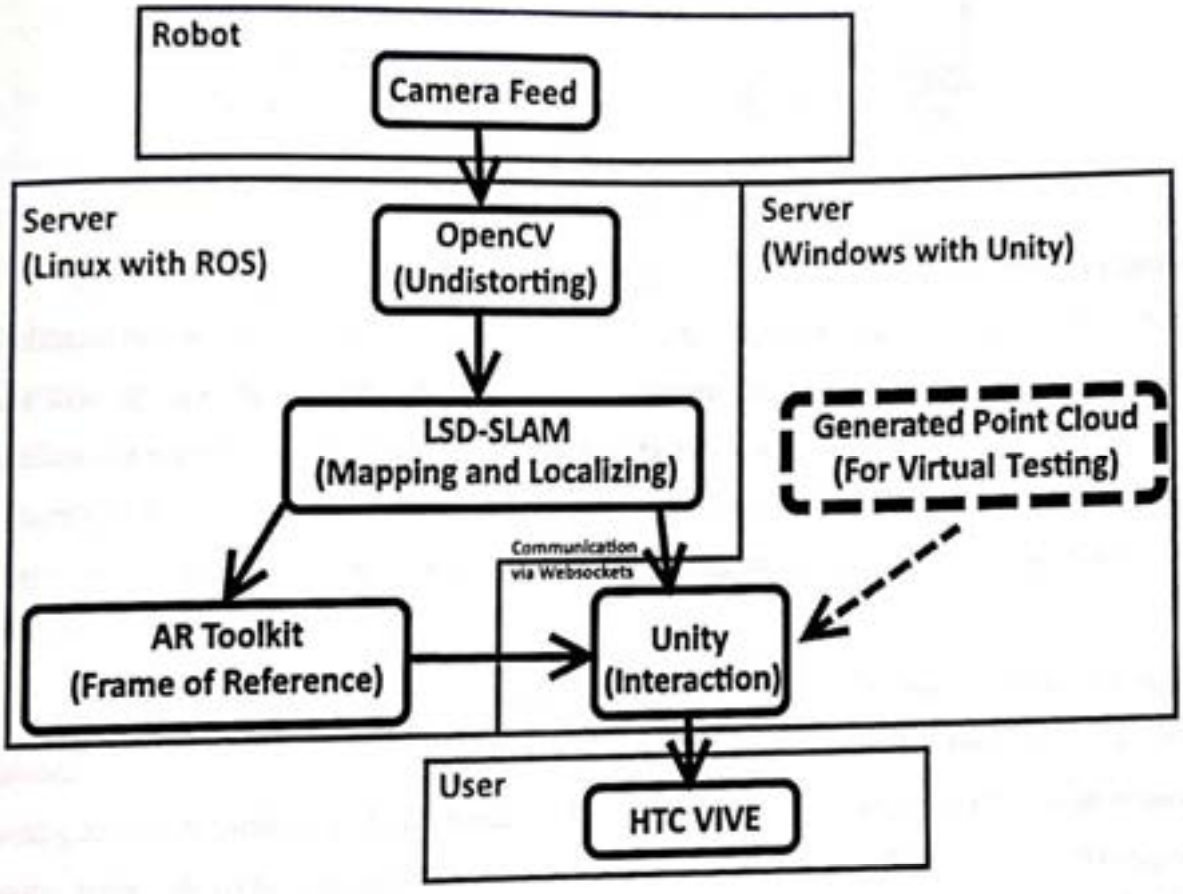

Figure 3.1 Block diagram for AR

3.5 Hardware

3.5.1 Display

Various technologies are used in augmented reality rendering, including optical projection systems, monitors, handheld devices, and display systems, which are worn on the human body.

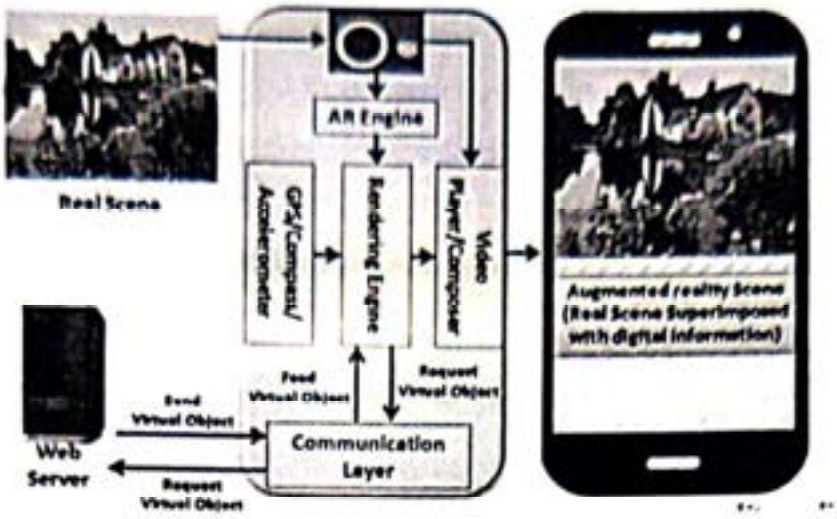

Figure 3.2 Function of AR

A head-mounted display (HMD) is a display device worn on the forehead, such as a harness or helmet-mounted. HMDs place images of both the physical world and virtual objects over the user's field of view. Modern HMDs often employ sensors for six degrees of freedom monitoring that allow the system to align virtual information to the physical world and adjust accordingly with the user's head movements. HMDs can provide VR users with mobile and collaborative experiences. Specific providers, such as uses and Gestigon, include gesture controls for full virtual immersion.

In January 2015, Meta launched a project led by Horizons Ventures, Tim Draper, Alexis Ohanian, BOE Optoelectronics and Garry Tan. On 17 February 2016, Meta announced their second-generation product at TED, Meta 2. The Meta 2 head-mounted display headset uses a sensory array for hand interactions and positional tracking, visual field view of 90 degrees (diagonal), and resolution display of 2560 x 1440 (20 pixels per degree), which is considered the largest field of view (FOV) currently available.

3.5.2 Eye classes

AR displays can be rendered on devices resembling eyeglasses. Versions include eyewear that employs cameras to intercept the real world view and re-display its augmented view through the eyepieces and devices in which the AR imagery is projected through or reflected off the surfaces of the eyewear lens pieces.

3.5.3 Contact lenses

Contact lenses that display AR imaging are in development. These bionic contact lenses might contain the elements for display embedded into the lens including integrated circuitry, LEDs and an antenna for wireless communication. The first contact lens display was reported in 1999, then 11 years later in 2010-2011. Another version of contact lenses, in development for the U.S. military, is designed to function with AR spectacles, allowing soldiers to focus on close-to-the-eye AR images on the spectacles and distant real world objects at the same time.

Many scientists have been working on contact lenses capable of different technological feats. A patent filed by Samsung describes an AR contact lens, that, when finished, will include a built-in camera on the lens itself. The design is intended to control its interface by blinking an eye. It is also intended to be linked with the user's smartphone to review footage, and control it separately. When successful, the lens would feature a camera, or sensor inside of it. It is said that it could be anything from a light sensor, to a temperature sensor.

In Augmented Reality, the distinction is made between two distinct modes of tracking, known as marker and marker less. Markers are visual cues which trigger the display of the virtual information. A piece of paper with some distinct geometries can be used. The camera recognizes the geometries by identifying specific points in the drawing. Marker less tracking, also called instant tracking, does not use markers. Instead, the user positions the object in the camera view preferably in a horizontal plane. It uses sensors in mobile devices to accurately detect the real-world environment, such as the locations of walls and points of intersection.

3.5.4 Virtual retinal display

A virtual retinal display (VRD) is a personal display device under development at the University of Washington's Human Interface Technology Laboratory under Dr.Thomas A. Furness III. With this technology, a display is scanned directly onto the retina of a viewer's eye. This results in bright images with high resolution and high contrast. The viewer sees what appears to be a conventional display floating in space.

Several of tests were done to analyse the safety of the VRD. In one test, patients with partial loss of vision having either macular degeneration (a disease that degenerates the retina)

or keratoconus were selected to view images using the technology. In the macular degeneration group, five out of eight subjects preferred the VRD images to the cathode-ray tube (CRT) or paper images and thought they were better and brighter and were able to see equal or better resolution levels. The Keratoconus patients could all resolve smaller lines in several line tests using the VDR as opposed to their own correction. They also found the VDR images to be easier to view and sharper. As a result of these several tests, virtual retinal display is considered safe technology.

Figure 3.3 Scanning process

Virtual retinal display creates images that can be seen in ambient daylight and ambient room light. The VRD is considered a preferred candidate to use in a surgical display due to its combination of high resolution and high contrast and brightness. Additional tests show high potential for VRD to be used as a display technology for patients that have low vision.

3.5.5 Spatial

Spatial augmented reality (SAR) augments real-world objects and scenes, without the use of special displays such as monitors, head-mounted displays or hand-held devices. SAR makes use of digital projectors to display graphical information onto physical objects. The key difference in SAR is that the display is separated from the users of the system. Since the displays are not associated with each user, SAR scales naturally up to groups of users, allowing for collocated collaboration between users.

Examples include shade lamps, mobile projectors, virtual tables, and smart projectors. Shade lamps mimic and augment reality by projecting imagery onto neutral objects. This provides

The VRD is considered a preferred candidate to use in a surgical display due to its combination of high resolution and high contrast and brightness. Additional tests show high potential for VRD to be used as a display technology for patients that have low vision.

3.5.5 Spatial

Spatial augmented reality (SAR) augments real-world objects and scenes, without the use of special displays such as monitors, head-mounted displays or hand-held devices. SAR makes use of digital projectors to display graphical information onto physical objects. The key difference in SAR is that the display is separated from the users of the system. Since the displays are not associated with each user, SAR scales naturally up to groups of users, allowing for collocated collaboration between users.

Examples include shade lamps, mobile projectors, virtual tables, and smart projectors. Shade lamps mimic and augment reality by projecting imagery onto neutral objects. This provides

the opportunity to enhance the object's appearance with materials of a simple unit—a projector, camera, and sensor.

Other applications include table and wall projections. One innovation, the Extended Virtual Table, separates the virtual from the real by including beam-splitter mirrors attached to the ceiling at an adjustable angle. Virtual showcases, which employ beam splitter mirrors together with multiple graphics displays, provide an interactive means of simultaneously engaging with the virtual and the real. Many more implementations and configurations make spatial augmented reality display an increasingly attractive interactive alternative.

A SAR system can display on any number of surfaces in an indoor setting at once. SAR supports both a graphical visualization and passive haptic sensation for the end users. Users are able to touch physical objects in a process that provides passive haptic sensation.

3.5.6 Tracking

Modern mobile augmented-reality systems use one or more of the following motion tracking technologies: digital cameras and/or other optical sensors, accelerometers, GPS, gyroscopes, solid state compasses, Radio-frequency identification (RFID). These technologies offer varying levels of accuracy and precision. The most important is the position and orientation of the user's head. Tracking the user's hand(s) or a handheld input device can provide a 6DOF interaction technique.

3.5.7 Networking

Mobile augmented reality applications are gaining popularity because of the wide adoption of mobile and especially wearable devices. However, they often rely on computationally intensive computer vision algorithms with extreme latency requirements. To compensate for the lack of computing power, offloading data processing to a distant machine is often desired. Computation offloading introduces new constraints in applications, especially in terms of latency and bandwidth. Although there are a plethora of real-time multimedia transport protocols, there is a need for support from network infrastructure as well.

3.5.8 Input devices

Techniques include speech recognition systems that translate a user's spoken words into computer instructions, and gesture recognition systems that interpret a user's body movements by visual detection or from sensors embedded in a peripheral device such as a wand, stylus, pointer, glove or other body wear. Products which are trying to serve as a controller of AR headsets include Wave by See bright Inc. and Nimble by Intugine Technologies.

3.6 Software and algorithms

A key measure of AR systems is how realistically they integrate augmentations with the real world. The software must derive real world coordinates, independent of camera, and camera images. That process is called image registration, and uses different methods of computer vision, mostly related to video tracking. Many computer vision methods of augmented reality are inherited from visual odometer.

Usually those methods consist of two parts. The first stage is to detect interest points, fiducial markers or optical flow in the camera images. This step can use feature detection methods like corner detection, blob detection, edge detection or thresholding, and other image processing methods. The second stage restores a real world coordinate system from the data obtained in the first stage. Some methods assume objects with known geometry (or fiducial markers) are present in the scene. In some of those cases the scene 3D structure should be calculated beforehand. If part of the scene is unknown simultaneous localization and mapping (SLAM) can map relative positions. If no information about scene geometry is available, structure from motion methods like bundle adjustment are used. Mathematical methods used in the second stage include: projective (epipolar),geometry, geometricalgebra, rotationrepresentation with exponentia lmap, kalman and particle filters, nonlinear optimization, robust statistics.

3.6.1 Development

The implementation of augmented reality in consumer products requires considering the design of the applications and the related constraints of the technology platform. Since AR systems rely heavily on the immersion of the user and the interaction between the user and the system, design can facilitate the adoption of virtuality. For most augmented reality systems, a similar design

guideline can be followed. The following lists some considerations for designing augmented reality applications.

3.6.2 Interaction design

Interaction design in augmented reality technology centres on the user's engagement with the end product to improve the overall user experience and enjoyment. The purpose of interaction design is to avoid alienating or confusing the user by organizing the information presented. Since user interaction relies on the user's input, designers must make system controls easier to understand and accessible. A common technique to improve usability for augmented reality applications is by discovering the frequently accessed areas in the devices touch display and design the application to match those areas of control. It is also important to structure the user journey maps and the flow of information presented which reduce the system's overall cognitive load and greatly improves the learning curve of the application.

In interaction design, it is important for developers to utilize augmented reality technology that complement the system's function or purpose. For instance, the utilization of exciting AR filters and the design of the unique sharing platform in Snapchat enables users to better the user's social interactions. In other applications that require users to understand the focus and intent, designers can employ a reticule or ray cast from the device. Moreover, augmented reality developers may find it appropriate to have digital elements scale or react to the direction of the camera and the context of objects that can are detected.

Augmented reality technology allows to utilize the introduction of 3D space. This means that a user can potentially access multiple copies of 2D interfaces within a single AR application.

3.6.3 Visual design

In general, visual design is the appearance of the developing application that engages the user. To improve the graphic interface elements and user interaction, developers may use visual cues to inform the user what elements of UI are designed to interact with and how to interact with them. Since navigating in an AR application may appear difficult and seem frustrating, visual cue design can make interactions seem more natural.

In some augmented reality applications that use a 2D device as an interactive surface, the 2D control environment does not translate well in 3D space making users hesitant to explore their surroundings. To solve this issue, designers should apply visual cues to assist and encourage users to explore their surroundings.

It is important to note the two main objects in AR when developing VR applications: 3D volumetric objects that are manipulated and realistically interact with light and shadow; and an animated media imagery such as images and videos which are mostly traditional 2D media rendered in a new context for augmented reality. When virtual objects are projected onto a real environment, it is challenging for augmented reality application designers to ensure a perfectly seamless integration relative to the real-world environment, especially with 2D objects. As such, designers can add weight to objects, use depths maps, and choose different material properties that highlight the object's presence in the real world. Another visual design that can be applied is using different lighting techniques or casting shadows to improve overall depth judgment. For instance, a common lighting technique is simply placing a light source overhead at the 12 o'clock position, to create shadows on virtual objects.

3.7 Results and Discussion

The summaries give a brief explanation of the research conducted within each resource. This provides a basic understanding of the reasoning behind the categorization of each resource both for the type of technology used as well as the design process stage(s).

In this thesis an AR prototype was developed for navigational purposes and tested against Google Maps in an experimental study with the focus on the usability requirements learnability. When the prototype was evaluated the results showed that for navigation when walking, Google Maps might be more suitable as the world looks today with the technology at hand but for navigation when driving, an AR application will probably benefit the driver more than using a standardized map application such as Google Maps. When looking at the separate usability requirements the prototype performed as expected on learnability, whilst the usability requirement was negligible for Google Maps since all the test subjects had already used it. There were negligible differences in efficiency, there were some differences in effectivity that favored Google Maps and lastly, Google Maps performed better in user satisfaction. Even though the prototype did not

perform as well as hypothesized based on the literature review, the test gave indication on that there is a lot of future work that can be done in this field and that the concept of augmented reality is highly current in the strive of bringing the virtual into our lives and in the concept of the technology adapting to the user and not the other way around.

3.8 Conclusion

At every new inflection in communication technology, the marketing and advertising community brought their existing models with them in their first efforts to adapt to the new medium. Radio, television, Internet, Web, and Mobile have all seen this progression play out and VR and AR will likely follow that model too Augmented Reality is a technology that has changed the face of smartphone apps and gaming. AR adds digital images and data to amplify views of the real world, giving users more information about their environments. This step is beyond virtual reality, which attempts to simulate reality. AR apps are growing at a tremendous speed as they give businesses a different edge which attracts the customers.

3.8 Applications

From gaming and entertainment to medicine, education and business.

4.3 Introduction of Unity Software

Unity is a cross-platform game engine developed by Unity Technologies, first announced and released in June 2005 at Apple Inc.'s Worldwide Developers Conference as a Mac OS X-exclusive game engine. As of 2018, the engine had been extended to support more than 25 platforms. The engine can be used to create three-dimensional, two-dimensional, virtual reality, and augmented reality games, as well as simulations and other experiences. Unity is a cross platform game engine developed by unity technologies first announced and released in June 2005 at Apple in worldwide developers .The engine is used to create 3D and 2D virtual reality and augmented reality games as well as simulation and other experiences. The engine has been adopted by industries such as film automotive, architecture, engineering and construction.

4.4 The Android Platform

The android platform allows developers to write managed code using java to manage and to control the android devices. Android studio is a popular IDE developed by goggle for developing applications that are targeted to the android platform.

Visual Studio

Its main purpose is to provide the ecosystem and languages support. It is commercial ion of visual studio. It comes in visual studio in 2010 and later version.

The application is split into two main parts: a tutorial section with an interactive 3D odel of the ventricular system and an educational animation on CSF flow; and a test-your-owledge area with a labelling challenge and multiple choice quiz at different difficulty levels, owing the user to test themselves on what they have learned in the tutorial section. The mmaries give a brief explanation of the research conducted within each resource.

Working Methods

Unity is a cross-platform game engine with a built-in IDE developed by Unity chnologies. It is used to develop video games for web plugins, desktop platforms, consoles nd mobile devices.

(1) A **game engine**, that allows game created to run (hence to be played) in different nvironments,

2) An application where the "visible pieces" of a game can be put together (the ***IDE***) with a raphical preview and using a controlled "play it" function, and

(3) a **code editor** (the one provided is Mono Develop, but developers can use others; yes I know that code writing is usually classified as part of the IDE, but for the sake of clarity of what follows, let's keep it as a separate piece).

So once you have the game design and all the required skills you can put together graphics, sounds, animations in Unity's IDE, write in the editor the code associated to the assets and then generate a playable application that runs in several different environments, as one of the features of Unity is that it is multi-platform, that is more or less the same game can run similarly on an iPad or on Windows.

The process I just outlined is intrinsically quite complicated – videogames are complex structures. Unity provides a complete workflow and a lot of help along the line, and a large set of features come in Unity's free version (see below). But IDE for games have been around for quite a while. This provides a basic understanding of the reasoning behind the categorization of each resource both for the type of technology used as well as the design process stage(s).

Figure 4.1 Overview in unity process

The application is split into two main parts: a tutorial section with an interactive 3D model of the ventricular system and an educational animation on CSF flow; and a test-your-knowledge area with a labelling challenge and multiple choice quiz at different difficulty levels, allowing the user to test themselves on what they have learned in the tutorial section. The summaries give a brief explanation of the research conducted within each resource.

4.7 Conclusion

Unity gives users the ability to create games and experiences in both 2D and 3D, and the engine offers a primary scripting API in C#, for both the Unity editor in the form of plugins, and games themselves, as well as drag and drop functionality. Within 2D games, Unity allows importation of sprites and an advanced 2D world renderer. For 3D games, Unity allows specification of texture compression, mini maps, and resolution settings for each platform that the game engine supports. Unity has been used to create approximately half of the new mobile games on the market and 60 percent of augmented reality and virtual reality content.

CHAPTER 5

WORK TO BE DONE IN PHASE –II

Our project aim is to develop an android development application for navigation map using unity software. In phase I we have learned the basics of Unity software and we have given the procedure, block diagram, how to develop an app using UNITY software. In phase II we will be develop the application for navigation map using software in augmented reality.

OCTOBER 2019

ABSTRACT

In our project, we introduce the creation of a cyber-physical system that controls environmental circumstances or environmental conditions in distant places in indoor areas. Communication between the parts of the system is carried out using the existing wireless infrastructure based on IEEE standards of 802.11 b / g. The resulting solution provides the opportunity to log measurements from locations around the world and to visualize and analyze the data collected from any device connected to the Internet. This work includes the full solution, a cyber-physical system beginning from the physical stage, composed of sensors and communication protocol, and achieving cyber-level data management and storage. The experimental findings indicate that the suggested scheme for environmental and ambient tracking apps is a feasible and simple solution.

CHAPTER 1

INTRODUCTION

1.1 Introduction

A sensor is able to convert physical or chemical readings gathered from the environment into signals that can be calculated by a system. A multi sensor node is able to sense several magnitudes in the same device. In a multi sensor, the input variables might be temperature (it is also able to capture nippy changes of temperature), fire, infrared radiation, humidity, smoke and CO_2.

A wireless sensor network could be a useful architecture for the deployment of the sensors used for fire detection and verification. The most vital factors for the quality and productivity of plant growth are temperature, humidity, light and the level of the carbon dioxide. Constant monitoring of these environmental variables gives information to the farmer to better understand, how each factor affects growth and how to manage maximal crop productiveness.

The optimal greenhouse climate adjustment can facilitate us to advance productivity and to achieve remarkable energy saving, particularly during the winter in northern countries. In the past generation greenhouses it was enough to have one cabled measurement point in the middle to offer the information to the greenhouse automation system.

The system itself was typically simple without opportunities to manage locally heating, lights, ventilation or some other activity, which was affecting the greenhouse interior climate. The typical size of the greenhouse itself is much larger than it was before, and the greenhouse facilities provide several options to make local adjustments to the light, ventilation and other greenhouse support systems. However, additional measurement data is also needed to construct this kind of automation system to work properly. Increased number of measurement points must not dramatically augment the automation system cost. It should also be possible to easily alter the location of the measurement points according to the particular needs, which depend on the specific plant, on the possible changes in the external weather or greenhouse structure and on the

plant placement in the greenhouse. Wireless sensor network can form a useful part of the automation system architecture in modern greenhouses constructively. Wireless communication can be used to collect the measurements and to communicate between the centralized control and the actuators located to the different parts of the greenhouse. In advanced WSN solutions, some parts of the control system itself can also be implemented in a distributed manner to the network such that local control loops can be formed. Compared to the cabled systems, the installation of WSN is fast, cheap and easy. Moreover, it is easy to relocate the measurement points when needed by just moving sensor nodes from one location to another within a communication range of the coordinator device.

If the greenhouse vegetation is high and dense, the small and light weight nodes can even be hanged up to the plants' branches. WSN maintenance is also relatively cheap and easy. The only additional costs occur when the sensor nodes run out of batteries and the batteries need to be charged or replaced, but the lifespan of the battery can be several years if an efficient power saving algorithm is applied. In this work, the very first steps towards the wireless greenhouse automation system by building a wireless measuring system for that purpose is taken and by testing its feasibility and reliability with a simple experimental setup. Clustering may be centralized or distributed, based on the arrangement of CH. In centralized clustering, the CH is preset but in distributed clustering CH has no fixed architecture. Distributed clustering mechanism is used for some private reasons like sensor nodes prone to failure, better collection of data and minimizing redundant information. Hence these distributed clustering mechanisms encompass highly self-organizing capability.

CHAPTER 2

LITERATURE SURVEY

2.1 A Cyber-Physical System for Environmental Monitoring on WSN

National Institute of Standards and Technology Special Publication 1900-202

Nat. Inst. Stand. Technol. Spec. Publ. 1900-202, 61 Pages (March 2006)

2.1.1 Introduction

The vitality from claiming natural screening will be undoubted for our age. This will be the field the piace remote sensor networks (WSNs) need been initial used, their basic role comprising in the perception of the physical reality and the recording of physical amounts characterizing it. The constant attempts of social and economic bodies for the improvement of technologies to develop energy efficiency and to pollution and for the more efficient use of national infrastructure along with the needs of decreasing the reduce cost of computation, networking, and sensing had led to the emergence of a new era of advanced systems, called cyber-physical systems (CPSs), less than a decade ago.

These include embedded systems, sensor networks, actuators, communication and management processes, and services to collect physical information and to work on the physical environment, all integrated under an intelligent decision system. This paper presents a system for environmental and ambient parameter monitoring using low-power wireless sensors connected to the Microcontroller, which send their measurements to a central server using the IEEE 802.11 b/g standards. Finally, data from all over the world, stored on the base station, can be remotely visualized from every device connected to the Internet. This overcomes the problem of system integration and interoperability, providing a well-defined architecture that simplifies the transmission of data from sensors with different measurement capabilities and increases supervisory efficiency.

2.1.2 Techniques

The document includes a development of monitoring solutions that credited from the advantages provided by wireless sensing technology. George Mois presented the development of a cyber-physical system that monitors the environmental conditions or the ambient conditions in indoor spaces at remote locations. The resulted solution provides the possibility of taking measurements from locations all over the world and of visualizing and examining the gathered data from any device connected to the framework. This work encompasses the complete solution, a cyber-physical system, starting from the physical level, consisting of sensors and the communication protocol, and reaching data management and storage at the cyber level . The experimental results show that the proposed system represents a viable and straightforward solution for environmental and ambient monitoring applications. An automated irrigation system based on a distributed wireless framework of soil wetness and temperature sensors that results water savings of 90% compared with classical implementations. It presents a smart monitoring solution for the assessment of possible causes of power inefficiency at the photovoltaic panel level based on WSNs.

The work presented here leads to a ubiquitous network architecture, where the sensors are part of the Internet. The developed monitoring solution, a CPS that incorporates all the developed Wi-Fi sensors and a cloud platform, allows the acquisition of data from every place where a wireless IEEE 802.11 network exists and the visualization of recorded data from every terminal connected to the Internet, without any additional hardware and software application other that an Internet browser.

- A Beagle bone black embedded processor with programmable system on chip (PSOC3).

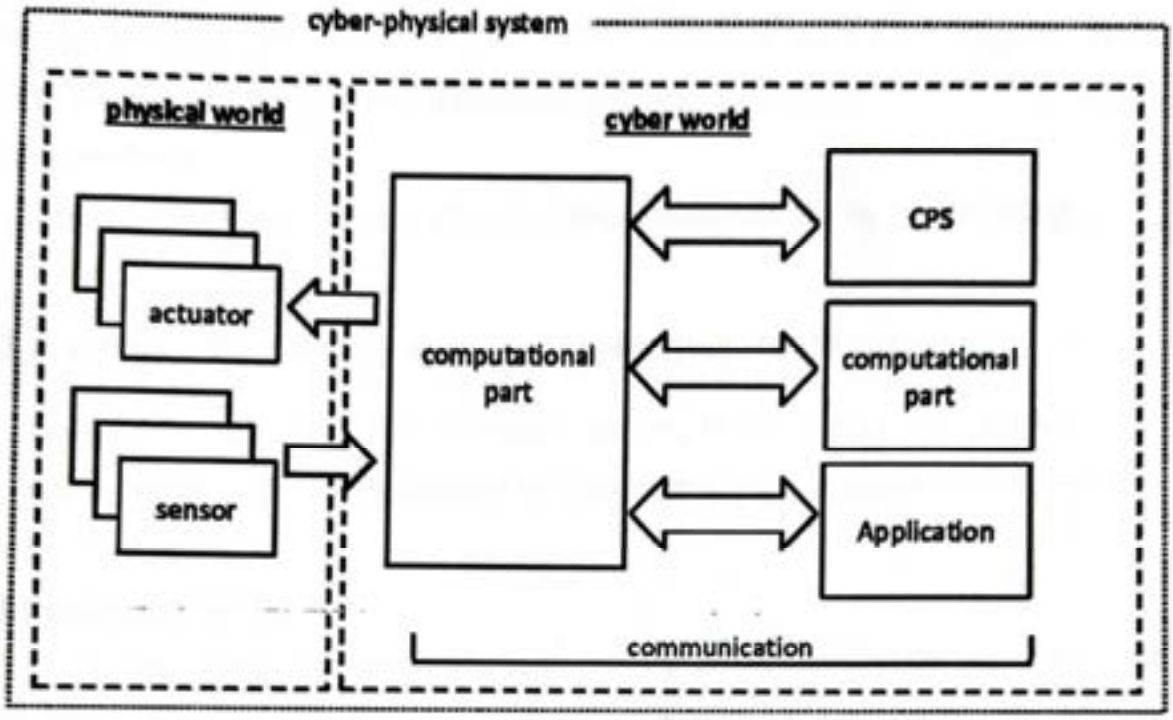

Fig 2.1 Block diagram of CPS system

2.1.3 Result

A number of experiments were performed by George Moise and team to provide reliability and better performance to the data transmission from experimental setup to the host computers. Firstly they tested for server's capabilities to this way and more data can be saved. The second experiment by George Mois and team was with single IOT platform with 4 PCs, which was wirelessly connected. Two time windows were used to transmit one package. The result shows that if period increases, the package loss ratio decreases process large quantity of received messages from nodes in a short time interval (window). The aim behind these tests was to examine the maximum number of packages that can be evaluated in short time interval for a single IOT platform. Figure 6 shows that the losses are reduced.

2.1.4 Conclusion

The improvement of a CPS, it utilizes sensors measuring the encompassing or the environment, which send messages to an IOT stage utilizing UDP. The correspondence protocol and the plan of the hubs help over accomplishing low power consumption, offering battery lifetimes for a long time. The framework dispenses with

cumbersome solutions, gives the likelihood about logging information the place Wi-Fi organize scope exists, furthermore might be utilized within an extensive variety from claiming checking provisions. Future worth of effort means on upgrade those dependability and security of the recommended framework.

2.1.5 Drawback

Expensive hardware, number of sent packages increases, the losses also increase.

2.2 A Cyber - Physical System for Environmental Monitoring

George Mois, Member, IEEE, Teodora Sanislav, Member, IEEE, and Silviu C. Folea, Member, IEEE Transactions on Instrumentation And Measurement, Vol. 65, No. 6, June 2016

2.2.1 Introduction

The importance of environmental monitoring is undoubted in our age. This is the field where wireless sensor networks (WSNs) have been first used, their primary purpose consisting in the observation of the physical world and the recording of physical quantities characterizing it. WSNs are large networks of resource-constrained sensors with processing and wireless communication capabilities, which implement different application objectives within a specific sensing field.

They can also be used for ambient monitoring, a topic of great interest nowadays as well, indoor air quality representing an important factor affecting the comfort, health, and safety of building occupants. Finally, the use of wireless ambient sensors can lead to more energy efficient buildings. The constant attempts of social and economic bodies for the development of technologies for improving energy efficiency and reducing pollution and for the more efficient use of national infrastructure along with the needs of decreasing the cost of computation, networking, and sensing had lead to the emergence of a new generation of digital systems, called cyber-physical systems (CPSs), less than a decade ago.

These include embedded systems, sensor networks, actuators, coordination and management processes, and services to capture physical data and to act on the physical environment, all integrated under an intelligent decision system . In this context, wireless sensors can be used to collect physical information that is further exploited by

CPSs. This will lead to CPSs composed of interconnected clusters of processing elements and large-scale wired and wireless networks of sensors and actuators gathering data about and acting upon the environment. These newly appeared systems have a lot of similarities with the Internet of Things (IoT), anenabler of ubiquitous sensing, that envisions a world in which many billions of Internet-connected objects or things, with sensing, communication, computing, and potentially actuating capabilities, will coexist, allowing an uninterrupted connection between people and things.

This paper presents a system for environmental and ambient parameter monitoring using low-power wireless sensors connected to the Internet, which send their measurements to a central server. Finally, data from all over the world, stored on the base station, can be remotely visualized from every device connected to the Internet. This overcomes the problem of system integration and interoperability, providing well defined architecture that simplifies the transmission of data from sensors with different measurement capabilities and increases supervisory efficiency.

Until recently, Wi-Fi technology has not been considered for implementing wireless sensing solutions because of its inability to meet the challenges in these types of systems, with the major drawback consisting in the unsatisfactory energy consumption. However, this has changed, since new power-efficient Wi-Fi devices have been developed and new solutions can benefit from several advantages offered by this technology, namely, the reduction of infrastructure costs while improving total ownership costs, native IP-network compatibility, and the existence of familiar protocols and management tools. Furthermore, high transmission rates, which are required in industrial applications, are achievable and the access to the network in this case is easy and no special wireless.

2.2.2 Objective

The resulted solution provides the possibility of logging measurements from locations all over the world and of visualizing and analyzing the gathered data from any device connected to the Internet. This work encompasses the complete solution, a cyber-physical system, starting from the physical level, consisting of sensors and the communication protocol, and reaching data management and storage at the cyber level. The experimental results show that the proposed system represents a viable and straightforward solution for environmental and ambient monitoring applications.

2.2.3 Techniques

Micro controller

This section forms the control unit of the whole project. This section basically consists of a Microcontroller with its associated circuitry like Crystal with capacitors, Reset circuitry, Pull up resistors (if needed) and so on. The Microcontroller forms the heart of the project because it controls the devices being interfaced and communicates with the devices according to the program being written.

ARM7TDMI

ARM is the abbreviation of Advanced RISC Machines, it is the name of a class of processors, and is the name of a kind technology too. The RISC instruction set, and related decode mechanism are much simpler than those of Complex Instruction Set Computer (CISC) designs.

Liquid-crystal display (LCD)

LCD is a flat panel display, electronic visual display that uses the light modulation properties of liquid crystals. Liquid crystals do not emit light directly. LCDs are available to display arbitrary images or fixed images which can be displayed or hidden, such as preset words, digits, and 7-segment displays as in a digital clock.

Temperature sensor

A thermistor is a type of resistor whose resistance is dependent on temperature. Thermistor are widely used as inrush current limiter, temperature sensors (NTC type typically), self-resetting over current protectors, and self-regulating heating elements. The TMP103 is a digital output temperature sensor in a four-ball wafer chip-scale package (WCSP). The TMP103 is capable of reading temperatures to a resolution of 1°C.

Co_2 sensor

They are used in gas leakage detecting equipment in family and industry, are suitable for detecting of LPG, i-butane, propane, methane, alcohol, Hydrogen, smoke. The surface resistance of the sensor Rs is obtained through effected voltage signal output of the load resistance RL which series-wound. The relationship between them is described: Rs\RL = (V_c-VRL) / VRL.

PROPOSED SCHEME

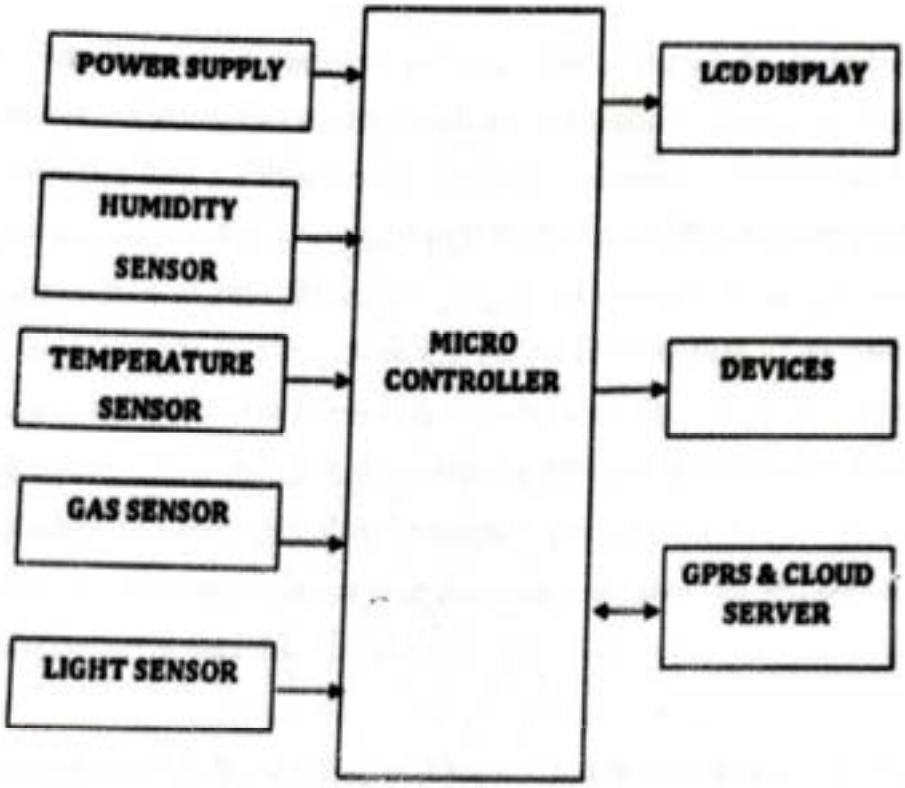

Fig 2.2 Block diagram of proposed scheme using microcontroller

Humidity sensor

Humidity sensor is a device that measures the relative humidity of in a given area. A humidity sensor can be used in both indoors and outdoors. Humidity sensors are available in both analog and digital forms. An analog humidity sensor gauges the humidity of the air relatively using a capacitor-based system. The sensor is made out of a film usually made of either glass or ceramics. The insulator material which absorbs the water is made out of a polymer which takes in and releases water based on the relative humidity of the given area. This changes the level of charge in the capacitor of the on board electrical circuit.

A digital humidity sensor works via two micro sensors that are calibrated to the relative humidity of the given area. These are then converted into the digital format via an analog to digital conversion process which is done by a chip located in the same

circuit. A machine made electrode based system made out of polymer is what makes up the capacitance for the sensor. This protects the sensor from user front panel (interface).

LDR

LDRs or Light Dependent Resistors are very useful especially in light/dark sensor circuits. Normally the resistance of an LDR is very high, sometimes as high as 1000 000 ohms, but when they are illuminated with light resistance drops dramatically. The animation opposite shows that when the torch is turned on, the resistance of the LDR falls, allowing current to pass through it. This is an example of a light sensor circuit. When the light level is low the resistance of the LDR is high. This prevents current from flowing to the base of the transistors. Consequently the LED does not light. However, when light shines onto the LDR its resistance falls and current flows into the base of the first transistor and then the second transistor. The LED lights on. The preset resistor can be turned up or down to increase or decrease resistance, in this way it can make the circuit more or less sensitivity.

GPRS

GPRS (general packet radio service) is a packet based data bearer service for wireless communication services that is delivered as a network overlay for GSM, CDMA and TDMA (ANSI-I36) networks. GPRS applies a packet radio principle to transfer user data packets in an efficient way between GSM mobile stations and external packet data networks. Packet switching is where data is split into packets that are transmitted separately and then reassembled at the receiving end. GPRS supports the world's leading packet-based Internet communication protocols, Internet protocol (IP) and X.25, a protocol that is used mainly in Europe. GPRS enables any existing IP or X.25 application to operate over a GSM cellular connection. Cellular networks with GPRS capabilities are wireless extensions of the Internet and X.25 networks.

2.2.4 Result

It employs sensors measuring the ambient or the environment, which send messages to an IoT platform using UDP. The communication protocol and the design of the nodes help in achieving low power consumption, offering battery lifetimes of several years. The system eliminates bulky solutions, provides the possibility of logging data where Wi-Fi network coverage exists, and can be used in a wide range of

monitoring applications. Future work intends to enhance the reliability and security of the proposed system.

2.2.5 Drawback

Trade - off between the amount of transmitted data and energy consumption.

2.3 A Real-time Cyber-Physical System for Indoor Environment Monitoring

Weihong Mi, Nanshu Zhou and Yaohui Jin International Conference on Manufacturing Science and Information Engineering (ICMSIE 2016) ISBN: 978-1-60595-325-0

2.3.1 Introduction

The last two decades have brought the revolution of internet and embedded system many devices are connected into the Internet. Thus, it makes possible for people to interact with physical world in which we live. The advancement in information technology led the need for a new generation of intelligent solutions on Cyber-Physical Systems. Cyber-physical systems integrate computing, communication and storage capability with monitoring. And it poses a set of advantages with efficient and safe, as well as allowing individual entities to form complex systems with new capacities.

A WSN (Wireless Senor Network) is consists of multiple low-power small embedded system and sensor nodes. It has communication, sensing and data storage, and processing capabilities. Due to the work of Giulio Gam-bardella etc. in micro-electromechanical systems, integrated circuits and radio frequency, WSNs are used in a wide range of applications, with emphasis on environment monitoring. The proposed CPS architecture acquires temperature humidity, noise, PM2.5 via sensors. And it senses the indoor environment well. With the development the technology of sensors, low cost, tiny size sensors are produced, that promotes the area in which environment monitoring, health care, industry automation.

In our system, data sensed by the sensor are sent by the User Datagram Protocol (UDP) to a measurements database, where they are collected. An intelligent cloud-based decision system transforms these sensing data into knowledge, reported to the end-users via restful API. Data or resources from devices or orders specified action to them need to be informed to users if users want to know environment where they are interested in.

Three kinds of protocol that suit for data transmission between devices and cloud are analyzed in, including: Constrained Application Protocol (Co AP), Message Queue Telemetry Transport (MQTT) and Extensible Messaging and Presence Protocol (XMPP). Co AP is running on top of UDP and only support a subset of the HTTP methods and REST full services.

Message Queue Telemetry Transport (MQTT) developed by IBM is another lightweight protocol for data transmission. Different from Co AP, MQTT is running on top of the TCP. UDP based Co AP is responsive than MQTT, but Co AP can cause longer delay at noisy channel because upper-layer retransmission mechanism is not very reactive compared to the TCP. XMPP is scalable and extensible for applications providing near real-time communication and robust delivery using TCP connection, usually used in Internet chatting.

In our system, the data model are built in the data proxy which is the bridge between local server with the cloud to make sure the reliable transmission i for device management and data collection. Thus, we choose MQTT protocol to transmit data from the local server to the cloud. The rest of this paper is structured as follows. In the next section, we make an overview of the existing Cyber-Physical system. In section3 detail architecture will be introduced about sensor hub. While in section 4, the device management and data distribution via restful API are described. The final section gives the conclusion and directions for future work.

2.3.2 Techniques

There are two important features, including management and real-time performance requirement. In, different models are discussed to implement Cyber-Physical system on the basics of 3S design that is, stability, security and systematic. Although the paper emphasized the stability, security and systematics when design a CPS, it ignore the real-time performance requirement and device management. It defines CPS architecture with three tiers and they overcome the difficulties with dynamic composition, dynamic adaptation and high confidence CPS management.

In fact, device management is taken into consideration based on users' requirement. But this is not enough in environment monitoring, in the most case user need to know the environment far away from them to make a better plan with their journey on real time. A cloud-based Cyber-Physical system is designed for

environmental monitoring. The architecture for this system consist of three layer the bottom layer, physical one, collecting data from sensor, the middle layer which is consist of data and knowledge, the top layer, namely application layer, provide users with service. This architecture takes real-time performance requirement into consideration.

The transmitted data represented as hexadecimal values and no time including the data. However, in the poor network condition, such as the network is not so stable, some of data may dismiss. Thus, it has bad influence on providing real-time service. What's worse, some of history data can't be acquired. Another disadvantage for the architecture is that it is lack of device management, it is not feasible to configure device with manual operation. In this paper, we introduce a novel architecture with a better data model and device management in the cloud. The sensor hub transmit data to the data proxy only if it shakes hand with data proxy. In the meantime, the information from the cloud are send to sensor hub to control the device and tag timestamp with sensor data. The proposed CPS architecture is presented in Figure.

2.3.2.1Wireless sensor hub

Sensor hub, who is responsible for sensing, collects and transports sensor data in real-time, is the key component of Wireless Sensor Network (WSN). The sensor hub should be designed for following requirements: Low power consumption, low cost, easy to be extended for new sensor and configurable in runtime, such as sensor enable/disable. A general purpose microprocessor generally has higher power consumption than a microcontroller; therefore it is often not considered a suitable choice for a sensor node. Hence, a battery powered embedded system with microcontroller as core component is a good choice for sensor hub. In our architecture, as Sensor hub is the core part of physical sensing layer and collects sensor data. In case of network being cut off by accident, a SD card is installed on the physical layer.

Proposed architecture

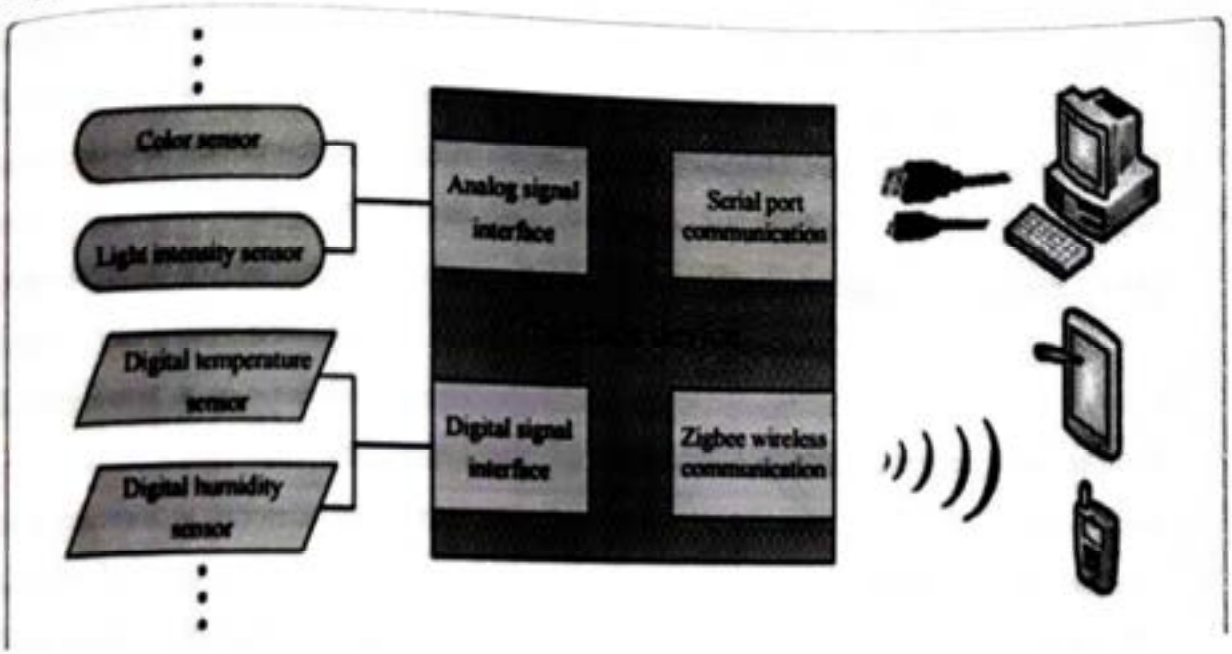

Fig 2.3 proposed CPS architecture

Even there is no network, the sensor hub continues working for a while and stores the data into SD card. When the network resume, the data saved in the SD card would be transmit to the cloud through WIFI. With integrated peripherals provide by sensor hub, many analog and digital sensor can be attached to sensor hub. In our proposed architecture, four sensors including temperature, humidity, noise and PM2.5 sensors compose the sensing part of sensor hub. Communication is performed by an RN-131C Wireless LAN model. We send data to the upper layer via UDP, since UDP is simplicity and less latency. it suitable for situation that has hard demand for real time requirement. However, there is no timestamp tagged with sensor data. Because, there is no timer on the sensor hub for the limit of power consumption.

Instead, the timestamp can be tagged when the data proxy communicating with sensor hub. When the sensor data transmit from sensor hub to data proxy, the processes are described as following and Figure3: Step1: sensor hub notifies the data proxy that data is going transmit from sensor hub to data proxy Step2: data proxy answer the sensor hub with time of local server. Step3: sensor hub checks the data frame from data proxy.

If there is no error, sensor hub will reconfigure the system with revised data including tagging timestamp with sensor data. Then sensor data will be transmitted to

data proxy via UDP. Or the sensor hub dismisses received data and keeps waiting for 3 seconds until it revives the correct data. If time goes out, sensor hub goes to step1. Step4: data proxy receives data and parses the frame ID of the data. Then frame ID is send to sensor hub to make sure that data has been received by data proxy. During the step2, not only timestamp can be sent, but also server IP, server port, SSID and password can be transport to sensor hub And sensor hub reconfigure system according data received from data proxy.

2.3.2.2 Data proxy and decision fusion based on the cloud

Data Proxy When the sensor hubs are in a subset of an organization, the need to be a gateway to forward data to the specific destination or the cloud. Two components consist the Data proxy: data model producer and MQTT client. When the data comes from sensor hub, the data model parses the information that user need and package the data with JSON format. Then, data is forwarded to the MQTT broker in cloud by MQTT broker.

2.3.2.3 Decision fusion the data management later meets the requirements

λ Provides device information and APIs to configure devices λ Data processing based on knowledge λ Provides analyses of environmental monitoring data for upper application According to section3, the data frame from sensor hub contain information about device, such as device mac, server IP, server Port, battery quantity etc. All the information is exposed to end-users. End-uses deduce the working condition of sensor hub to decide which sensor hub need to be replace with new or repaired by looking at the power of sensor hub in the cloud. In the meanwhile, some sensor data with low quality need to be cleared based on knowledge. the data distribution is implement with restful API.REST is an architectural model that can be efficiently implemented as a combination of the Hypertext Transfer Protocol (HTTP) and TCP/IP. Restful API has the advantage of cross-platform and it is friendly to developer.

2.3.4 Result

The paper proposed a real-time Cyber-Physical system for environmental monitoring based on WSNs and cloud computing. The architecture is designed according CPSs paradigm, and restful API are used to distribute sensor data for upper application. In this paper, we propose a method to tag time stamp with sensor data. Even under the poor network condition, the system senses environment without data missing.

2.3.5 Drawback

Expensive method

2.4 A Cyber–Physical System for Environmental Monitoring Through IOT Module

Pratik Padher, Dr. V.M.Rohokale IJEDR 2018 | Volume 6, Issue 3 | ISSN: 2321-9939

2.4.1 Introduction

A cyber physical system is being developed to monitor the environmental conditions or the ambient conditions in indoor spaces at remote locations. The communication between the system's components is performed using the existent wireless infrastructure. Some indoor places like poultry need continuous monitoring of few environmental parameters which cannot be identified by human. So there is a need for electronic equipment. We are using few sensors to detect and intimates to the controller which acts as heart of entire system.

2.4.2 Objective

In this project we are using moisture sensor, CO sensor, light sensor and Temperature sensor. Moisture sensor is arranged to check the moisture content, light/LDR sensor's output varies with the lighting at that place and informs the controller about this. Temperature sensor is given to identify about the abnormal change in temperature. Dangerous gas is sensed using CO sensor. All the parameters are being displayed on LCD and the same values are updated in the web server through IoT module interfaced to the controller. This is to make the information available about these parameters in the remote location also.

2.4.3 Techniques

This project uses sensors such as Humidity, Smoke Sensor, Temperature sensor (LM35).Whenever hazardous gas is detected then buzzer alert is given. The temperature sensor LM35 senses the temperature and converts it into an electrical (analog) signal. The analog signal is converted into digital format by the analog-to-digital converter (ADC). Then the fan will be ON. The status of every sensor will give updates through the IOT. Light gets on whenever LDR senses night mode. Motor will be on in case of dry condition detected by moisture sensor.

2.4.3.1 Wi-Fi module

ESP8266EX offers a complete and self-contained Wi-Fi networking solution; it can be used to host the application or to offload Wi-Fi networking functions from another application processor. When ESP8266EX hosts the application, it boots up directly from an external flash. In has integrated cache to improve the performance of the system in such applications. Alternately, serving as a Wi-Fi adapter, wireless internet access can be added to any micro controller-based design with simple connectivity (SPI/SDIO or I2C/UART interface).

2.4.3.2 LCD

LCD stands for Liquid Crystal Display. LCD is finding wide spread use replacing LEDs (seven segment LEDs or other multi segment LEDs) because of the following reasons: These components are "specialized" for being used with the microcontrollers, which means that they cannot be activated by standard IC circuits. They are used for writing different messages on a miniature LCD.

2.4.3.3 Temperature sensor

The LM35 series are precision integrated-circuit temperature sensors, whose output voltage is linearly proportional to the Celsius (Centigrade) temperature. The LM35 thus has an advantage over linear temperature sensors calibrated in ° Kelvin, as the user is not required to subtract a large constant voltage from its output to obtain convenient Centigrade scaling.

2.4.3.4 Light dependent resistor

LDR or Light Dependent Resistors are very useful especially in light dark sensor circuits. Normally the resistance of an LDR is very high, sometimes as high as 1000 000 ohms, but when they are illuminated with light resistance drops dramatically. The animation opposite shows that when the torch is turned on, the resistance of the LDR falls, allowing current to pass through it LDRs or Light Dependent Resistors are very useful especially in light/dark sensor circuits. Normally the resistance of an LDR is very high, sometimes as high as 1,000,000 ohms, but when they are illuminated with light, the resistance drops dramatically.

2.4.4 Result

The greenhouse vegetable production needs less labor, less capital, has faster returns than normal vegetable production. We have arranged few sensors to maintain environment automatically. The status of every sensor will given through the SMS. Here PIR, LDR sensors are also used and their respective relay are also activated accordingly.

2.4.5 Drawback

Low efficiency

2.5 A Real Time Cyber Physical System for Monitoring Environmental Status

International Journal of Electrical, Electronics and Data Communication, ISSN: 2320-2084

2.5.1 Introduction

The importance of environmental monitoring plays a vital role. This is the field where wireless sensor networks (WSNs) have been first used, their primary purpose consisting in the observation of the physical world and the recording of physical quantities characterizing it. CPSs composed of interconnected clusters of processing elements and large-scale wired and wireless networks.

The paper proposed a real-time Cyber-Physical system for environmental monitoring based on WSNs and cloud computing. The architecture is designed according CPSs paradigm, and restful API are used to distribute sensor data for upper application. In this paper, we propose a method to tag time stamp with sensor data. Even under the poor network condition, the system senses environment without data missing. We implemented and test the system and it works very well. But the control of the sensor hub is relatively centralized. That is not so good for device management when numbers of devices are connected into the system .A distributed strategy will be developed in the future work. The environment monitoring system (EMS) consists of three layers: physical sensing layer, data transport of sensors and actuators gathering data about and acting upon the environment.

These newly appeared systems have a lot of similarities with the Internet of Things (IoT), an enabler of ubiquitous sensing, that envisions a world in which many billions of Internet-connected objects or things, with sensing, communication,

computing, and potentially actuating capabilities, will coexist, allowing an uninterrupted connection between people and things. layer, data management layer. Generally, sensors and sensor hub which collects sensor data and transfer them to the upper layer make up of physical sensing layer. And the main function for data transport layer is to forward sensor data to the specified destination. The last layer is in the cloud, composed of a data processor and a knowledge base.

Data from physical sensing layer can be analyzed due to the strong computation ability of cloud computing. Also, there are abundant restful API (application programming interfaces) are provided by management layer based on users' demand. The proposed architecture provide convenient management with devices since all the information of devices are stored into database in the cloud. Even under the poor condition of network, data produced by sensors can be saved in local storage, making it enough time for user to settle the network problem with no affecting on the environment monitoring.

2.5.2 Objective

CYBER PHYSICAL SYSTEMS (CPS) represents a new generation of digital systems, where cyber entities and physical devices cooperate towards a set of common goals. This paper presents that the CPS monitors the environmental conditions in real time. The communication between the systems components is performed by using IEEE 802.11 b/g standards .It provides a possibility of logging into the system from anywhere in the world with the device connected to the internet.

2.5.3 Techniques

2.5.3.1 UDP port listener and message interpreter:

This component is in charge of listening the UDP port to which the sensors transmit the packets containing the measurement data. The data received are stored into a buffer and processed for being saved in a database. A benchmark program was written to compute the average processing time for each received message. This includes message interpretation and data saving into the database. An average period of 1.5 ms was observed for each data packet that was received and saved on the local memory.

2.5.3.2Database

The SQLite software library was chosen for storing the data received from the Wi-Fi sensors in a data- base.

2.5.3.3Web Server

An open source licensed small memory footprint Web server, namely, light pad was installed on the IoT platform for remote data visualization.

2.5.4 Result

The development of a CPS, which monitors environmental parameters based on the existent infrastructure, was presented. It employs sensors measuring the ambient or the environment, which send messages to an IoT platform using UDP. The system provides the possibility of logging data where Wi-Fi network coverage exists, can be used in a wide range of monitoring applications.

2.5.5 Drawback

Time consumption more

Speed is less

2.6 A Cyber-Physical System for Environmental Monitoring

George Mois, Member, IEEE, Teodora Sanislav, Member, IEEE, and Silviu C.Folea, Member, IEEE

2.6.1 Introduction

The importance of environmental monitoring is undoubted in our age. This is the field where wireless sensor networks (WSNs) have been first used, their primary purpose consisting in the observation of the physical world and the recording of physical quantities characterizing it. WSNs are large networks of resource-constrained sensors with processing and wireless communication capabilities, which implement different application objectives within a specific sensing field.

They can also be used for ambient monitoring, a topic of great interest now a days as well, indoor air quality representing an important factor affecting the comfort, health, and safety of building occupants. Finally, the use of wireless ambient sensors can lead to more energy-efficient buildings. The constant attempts of social and economic bodies for the development of technologies for improving energy efficiency and reducing pollution.

The Associate Editor coordinating the review process was Dr. Antonios Tsourdos. The authors are with the Department of Automation, Faculty of Automation and Computer Science. Color versions of one or more.

National infrastructure along with the needs of decreasing the cost of computation, networking, and sensing had lead to the emergence of a new generation of digital systems, called cyber-physical systems (CPSs), less than a decade ago. These include embedded systems, sensor networks, actuators, coordination and management processes, and services to capture physical data and to act on the physical environment, all integrated under an intelligent decision system. In this context, wireless sensors can be used to collect physical information that is further exploited by CPSs. This will lead to CPSs composed of interconnected clusters of processing elements and large-scale wired and wireless networks of sensors and actuators gathering data about and acting upon the environment.

The rest of this paper is structured as follows. The next section presents the context of the present work, while Section III talks about the current trends and also the motivation of using wireless sensors in the context of CPSs and of the IoT. Section IV gives a description of the developed CPS, with its two main components, the Wi-Fi sensors and the data-center. The general structure of the system and the main characteristics of the two types of devices are presented here. Section V presents the experimental results of the proposed system, highlighting the performances characteristics in terms of reliability influenced by package losses. Finally, Section VI gives the concluding remarks and the directions for future work.

2.6.2 Objective

The resulted solution provides the possibility of logging measurements from locations all over the world and of visualizing and analyzing the gathered data from any device connected to the Internet. This work encompasses the complete solution, a cyber-physical system, starting from the physical level, consisting of sensors and the communication protocol, and reaching data management and storage at the cyber level. The experimental results show that the proposed system represents viable and straightforward solution for environmental and ambient monitoring applications.

2.6.3 Techniques

Scopus is arguably the largest citation database and indexes approximately 15,000 peer-reviewed journals from more than publishers. This study chooses Cyber Physical System", as the keywords to search published papers from January 2012 to March 2017 collected by Scopus databases. Initially, articles are selected. After

removing irrelevant topics, articles in total are chosen and hence used as samples for this study. shows the statistics and trend of publications on CPS applications. shows the type of these publications.

2.6.4 Result

A number of experiments were performed for providing data related to the reliability and performance of the proposed system. The first two sets of experiments consisted in the testing of the server's capabilities of processing large numbers of messages received from sensors in a short period of time (named from here on also as time window). First, a desktop PC was used for sending UDP messages formatted as the ones sent by the two types of sensors to the server platform, and then four notebook PCs using wireless communication were used to send the same messages through UDP.

2.6.5 Conclusion

The development of a CPS, which monitors environmental parameters based on the existent IEEE 802.11 infrastructure, was presented. It employs sensors measuring the ambient or the environment, which send messages to an IoT platform using UDP. The communication protocol and the design of the nodes help in achieving low power consumption, offering battery lifetimes of several years. The system eliminates bulky solutions, provides the possibility of logging data where Wi-Fi network coverage exists, and can be used in a wide range of monitoring applications. Future work intends to enhance the reliability and security of the proposed system.

2.7 A Cyber - Physical System for Environmental Monitoring

International Journal of Electronics and Communication Engineering and Technology (IJECET) Volume 8, Issue 2, March - April 2017

2.7.1 Introduction

This is the field where wireless sensor networks (WSNs) have been first used, their primary purpose consisting in the observation of the physical world and the recording of physical quantities characterizing it. WSNs are large networks of resource-constrained sensors with processing and wireless communication capabilities, which implement different application objectives within a specific sensing field.

They can also be used for ambient monitoring, a topic of great interest nowadays as well, indoor air quality representing an important factor affecting the comfort, health, and safety of building occupants. Finally, the use of wireless ambient sensors can lead to more energy efficient buildings. The constant attempts of social and economic bodies for the development of technologies for improving energy efficiency and reducing pollution and for the more efficient use of national infrastructure along with the needs of decreasing the cost of computation, networking, and sensing had lead to the emergence of a new generation of digital systems, called cyber-physical systems (CPSs), less than a decade ago.

These include embedded systems, sensor networks, actuators, coordination and management processes, and services to capture physical data and to act on the physical environment, all integrated under an intelligent decision system . In this context, wireless sensors can be used to collect physical information that is further exploited by CPSs. allowing an uninterrupted connection between people and things. This paper presents a system for environmental and ambient parameter monitoring using low-power wireless sensors connected to the Internet, Finally, data from all over the world, stored on the base station, can be remotely visualized from every device connected to the Internet.

Until recently, Wi-Fi technology has not been considered for implementing wireless sensing solutions because of its inability to meet the challenges in these types of systems, with the major drawback consisting in the unsatisfactory energy consumption. However, this has changed, since new power-efficient Wi-Fi devices have been developed and new solutions can benefit from several advantages offered by this technology, namely, the reduction of infrastructure costs while improving total ownership costs, native IP-network compatibility, and the existence of familiar protocols and management tools., Furthermore, high transmission rates, which are required in industrial applications, are achievable and the access to the network in this case is easy and no special wireless.

2.7.2 Objective

The resulted solution provides the possibility of logging measurements from locations all over the world and of visualizing and analyzing the gathered data from any device connected to the Internet. This work encompasses the complete solution, a cyber-

physical system, starting from the physical level, consisting of sensors and the communication protocol, and reaching data management and storage at the cyber level. The experimental results show that the proposed system represents a viable and straightforward solution for environmental and ambient monitoring applications.

2.7.3 Techniques

2.7.3.1 Wi-Fi module

ESP8266EX offers a complete and self-contained Wi-Fi networking solution; it can be used to host the application or to offload Wi-Fi networking functions from another application processor. When ESP8266EX hosts the application, it boots up directly from an external flash. In has integrated cache to improve the performance of the system in such applications. Alternately, serving as a Wi-Fi adapter, wireless internet access can be added to any micro controller-based design with simple connectivity (SPI/SDIO or I2C/UART interface).

2.7.3.2 LCD

LCD stands for Liquid Crystal Display. LCD is finding wide spread use replacing LEDs (seven segment LEDs or other multi segment LEDs) because of the following reasons: These components are "specialized" for being used with the microcontrollers, which means that they cannot be activated by standard IC circuits. They are used for writing different messages on a miniature LCD.

2.7.3.3 Web Server

An open source licensed small memory footprint Web server, namely, light pad was installed on the IoT platform for remote data visualization.

2.7.4 Result

It employs sensors measuring the ambient or the environment, which send messages to an IoT platform using UDP. The system provides the possibility of logging data where Wi-Fi network coverage exists, can be used in a wide range of monitoring applications.

2.7.5 Drawback

Energy consumption is high.

2.8 A Cyber - Physical System for Environmental Monitoring

ISSN 2348 – 7968 IJISET - International Journal of Innovative Science, Engineering & Technology, Vol. 2 Issue 6, June 2015

2.8.1 Introduction

Cyber-physical system (CPS) is currently of interest in academia, industry, and government due to their potentially signicant impact on society, environment, and economy. Since, the National Science Foundation (NSF) has awarded large amount of funds to research on CPS. Many universities and institutes, such as UC Berkeley, Vanderbilt University, University of Memphis, University of Michigan, University of Notre Dame, University of Maryland, and General Motors Research and Development Center, join this research area the U.S. government has treated CPSs as a new development strategy. At the same time researchers from other countries have started to be aware of signicance for CPS research. In addition, many conferences and workshops on CPS have been organized, such as the CPS Week and the ACM/IEEE International Conference on Cyber-Physical Systems (ICCPS), respectively.

2.8.2 Technique

Scopus is arguably the largest citation database and indexes approximately peer-reviewed journals from more than publishers. This study chooses Cyber Physical System "CPS", and Application" as the keywords to search published papers from January to March collected by Scopus databases. Initially, are selected. After removing irrelevant topics, articles in total are chosen and hence used as samples for this study. shows the statistics and trend of publications on CPS applications. shows the type of these publications.

The number of conference papers is more than the number of journal articles. This indicates that there are many novel ideas in CPS research area. Among these publications, the journal papers are from journals during the study period. lists the journals. Three papers come from Proceedings of the IEEE, which has the highest number of publications. Most of these journals are in the fields of IEEE, computer science, and engineering.

2.8.3 Result

This paper conducts an extensive review of publications about CPS applications from collected in Elsevier's Scopus database, aiming to provide scholars and practitioners with a comprehensive overview on CPS applications. These publications are grouped into research categories. The contents of the papers in each research category are summarized. Challenges and trends in each research category are illustrated as well. Scholars can stay up to date with the latest studies on CPS and gain research ideas from this study. Practitioners can also learn new approaches and their effects from this study. As a very active research field, a variety of questions regarding CPS need to be solved, at different layers of the architecture and from different aspects of systems design, to trigger and to ease the integration of the physical and cyber worlds.

2.8.4 Conclusion

The major limitation of this study is that only the Scopus database was selected. Several other important CPS research fields are not covered in this paper, such as critical infrastructure control, distributed robotics, defense systems, and aerospace systems. Future research should review research on CPS based on other databases, such as SCI/SSCI, IEEE explore, and Google Scholar, to validate the findings in this study. In addition, this study only focuses on CPS applications, and research regarding CPS theoretical foundations is not covered. Future research needs to explore the development of CPS theories and technologies.

2.8.5 Drawbacks

There is no remote alert using IOT.

2.7 Summary of Literature Review

The summary of the literature review is given by **Table 2.1** contains title of the paper, techniques and its drawbacks.

Table 2.1 Summary of Literature Review

SNO	Title	Technique	Drawback
1	A Cyber - Physical System For Environmental Monitoring	This project uses sensors such as Humidity, Smoke Sensor, Temperature sensor (LM35). Whenever hazardous gas is detected then buzzer alert is given. The temperature sensor LM35 senses the temperature and converts it into an electrical (analog) signal. The analog signal is converted into digital format by the analog-to-digital converter (ADC).	Here and CO sensor and Air Moisture sensor are not there to identify human and dangerous gas. There is no remote alert using IOT.
2	Digitalized Cyber Physical System for Environmental Monitoring	These proposed solutions are based on ZigBee applications and under relay on gateways when the data has to be sent to the internet.	Time consumption more Speed is less
3	Review On - IoT Based Environment Monitoring System	This system consists of a microcontroller as a main processing unit for the entire system and all the sensor and devices can be connected with the microcontroller.	As network signals are not available, then locker may not be opened
4	A Cyber-Physical System for Environmental Monitoring	Real time air quality monitoring using WLAN, WSN, Embedded Systems. Wireless Sensors In Cyber-physical Systems	Energy consumption issue Large size Algorithms

5	Review on A cyber physical system for monitoring and controlling of industrial pollution using Raspberry Pi	Wireless Sensors In Cyber Physical System Interfacing	It is time consuming at initial stage
6	A Real-time Cyber-Physical System for Indoor Environment Monitoring	Data Proxy And Decision Fusion Based On The Cloud Data fusion and aggregations based on self organised map (SOM) algorithms.	Trade-off between the amount of transmitted data and energy consumption
7	Cyber-Physical Systems: A Literature Review	Transmission is achieved using local area networks, the Internet or communication technologies such as Wi-Fi, Bluetooth, ZigBee, and infrared. The application layer processes information from transmission layer and issues commands to be executed by the sensors and actuators. The main objective of the layer is to create a smart environment.	Expensive hardware, number of sent packages increases, the losses also increase
8	A Cyber - Physical System For Environmental Monitoring	A Beagle bone black embedded processor with programmable system on chip (PSOC3). Average Slope Multiplication (ASM) to classify odors using dynamic response of sensors.	Low efficiency

CHAPTER 3

THEORETICAL BACKGROUND

3.1 Introduction

A sensor is able to convert physical or chemical readings gathered from the environment into signals that can be calculated by a system. A multi sensor node is able to sense several magnitudes in the same device. In a multi sensor, the input variables might be temperature (it is also able to capture nippy changes of temperature), fire, infrared radiation, humidity, smoke and CO_2. A wireless sensor network could be an useful architecture for the deployment of the sensors used for fire detection and verification. The most vital factors for the quality and productivity of plant growth are temperature, humidity, light and the level of the carbon dioxide. Constant monitoring of these environmental variables gives information to the farmer to better understand, how each factor affects growth and how to manage maximal crop productiveness.

The optimal greenhouse climate adjustment can facilitate us to advance productivity and to achieve remarkable energy saving, particularly during the winter in northern countries. In the past generation greenhouses it was enough to have one cabled measurement point in the middle to offer the information to the greenhouse automation system. The system itself was typically simple without opportunities to manage locally heating, lights, ventilation or some other activity, which was affecting the greenhouse interior climate.

The typical size of the greenhouse itself is much larger than it was before, and the greenhouse facilities provide several options to make local adjustments to the light, ventilation and other greenhouse support systems. However, additional measurement data is also needed to construct this kind of automation system to work properly. Increased number of measurement points must not dramatically augment the automation system cost. It should also be possible to easily alter the location of the measurement points according to the particular needs, which depend on the specific plant, on the possible changes in the external weather or greenhouse structure and on the plant placement in the greenhouse.

Wireless sensor network can form a useful part of the automation system architecture in modern greenhouses constructively. Wireless communication can be used to collect the measurements and to communicate between the centralized control and the actuators located to the different parts of the greenhouse. In advanced WSN solutions, some parts of the control system itself can also be implemented in a distributed manner to the network such that local control loops can be formed. Compared to the cabled systems, the installation of WSN is fast, cheap and easy. Moreover, it is easy to relocate the measurement points when needed by just moving sensor nodes from one location to another within a communication range of the coordinator device. If the greenhouse vegetation is high and dense, the small and light weight nodes can even be hanged up to the plants' branches.

WSN maintenance is also relatively cheap and easy. The only additional costs occur when the sensor nodes run out of batteries and the batteries need to be charged or replaced, but the lifespan of the battery can be several years if an efficient power saving algorithm is applied. In this work, the very first steps towards the wireless greenhouse automation system by building a wireless measuring system for that purpose is taken and by testing its feasibility and reliability with a simple experimental setup. Clustering may be centralized or distributed, based on the arrangement of CH. In centralized clustering, the CH is preset but in distributed clustering CH has no fixed architecture. Distributed clustering mechanism is used for some private reasons like sensor nodes prone to failure, better collection of data and minimizing redundant information. Hence these distributed clustering mechanisms encompass highly self-organizing capability.

3.2 Block diagram

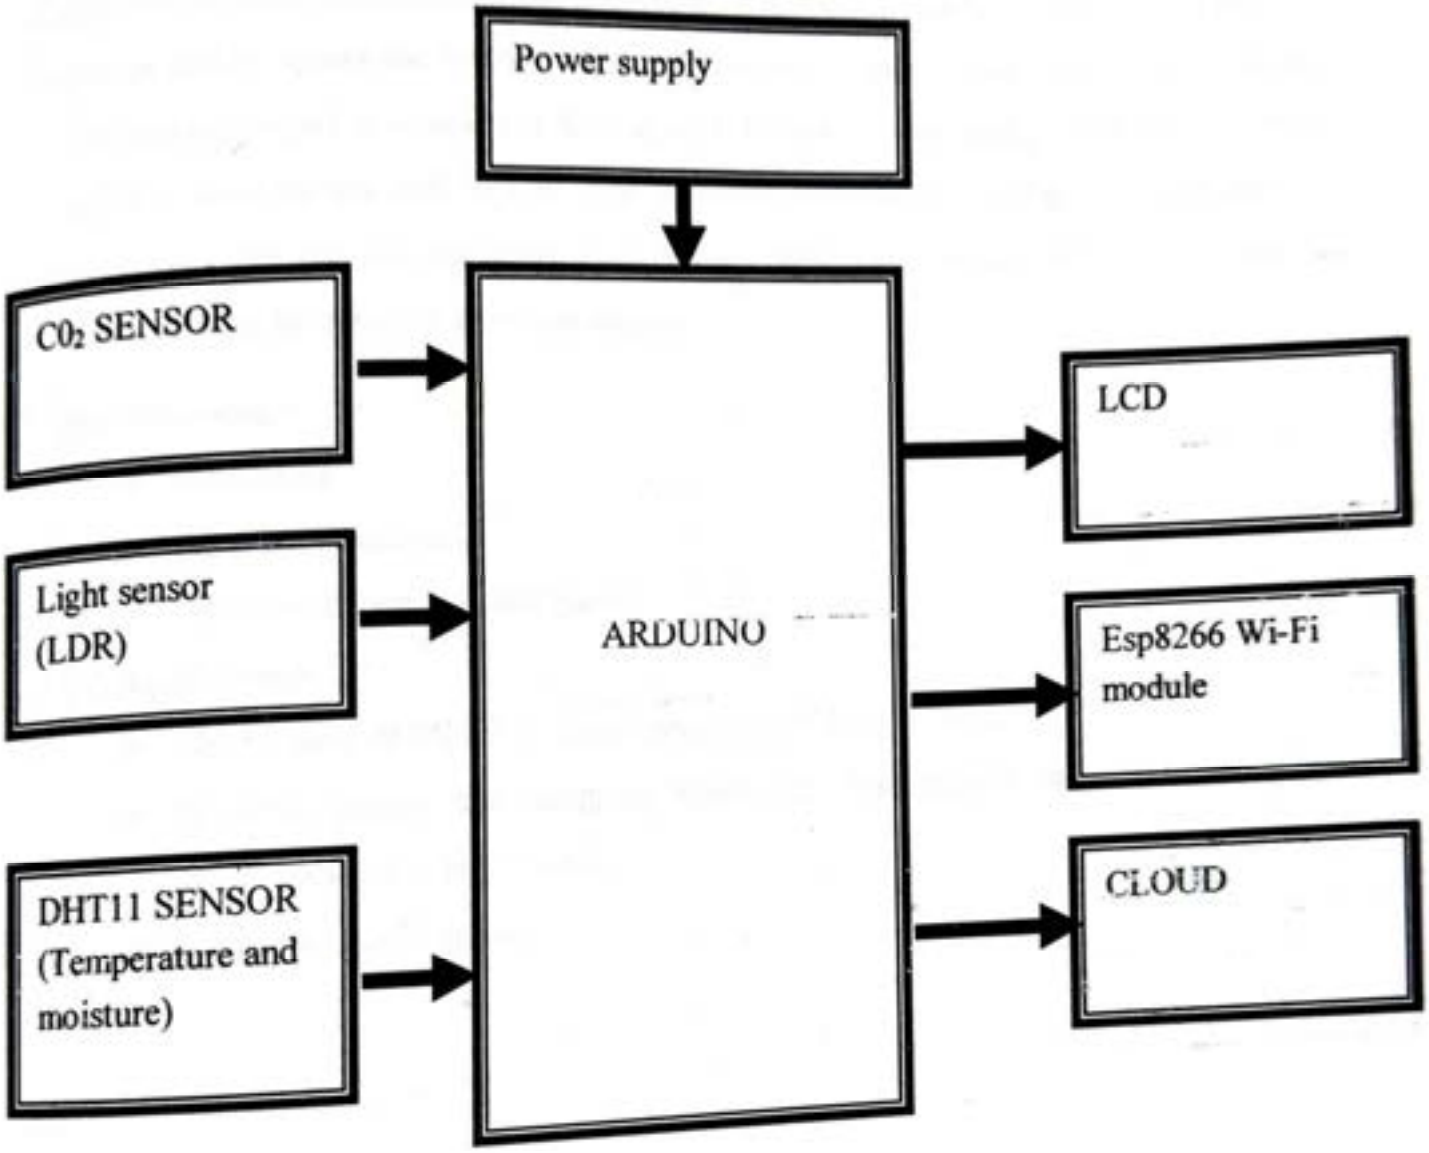

FIG 3.1 PROPOSED BLOCK DIAGRAM

3.3 Methodology

This project uses sensors such as Humidity, Smoke Sensor, Temperature sensor (LM35). Whenever hazardous gas is detected then buzzer alert is given. The temperature sensor LM35 senses the temperature and converts it into an electrical (analog) signal. The analog signal is converted into digital format by the analog-to-digital converter (ADC). Then the fan will be ON. The status of every sensor will give updates through the IOT. Light gets on whenever LDR senses night mode. Motor will be on in case of dry condition detected by moisture sensor.

3.4 Advantages

- Reliability
- Ease of Operation
- Useful to detect harmful gases

3.5 Applications

- Can be used in Mines to detect presence of dreadful gases.
- In public places like shopping malls, etc, this project can be applied where public safety is a major task.
- In Marine Applications.

CHAPTER 4

SYSTEM SPECIFICATION

4.1 Software Requirements

Simulator Tool : Arduino IDE

PHP

4.1.1 Hardware Requirements:

- C02 sensor
- DHT11 sensor
- Light sensor (LDR)
- ARDUINO
- LCD
- Esp8266 Wi-Fi module

4.2 Introduction to Arduino IDE

- Arduino IDE is open source software that is mainly used for writing and compiling the code into the Arduino Module.
- It is official Arduino software, making code compilation too easy that even a common person with no prior technical knowledge can get their feet wet with the learning process.
- It is easily available for operating systems like MAC, Windows, and Linux and runs on the Java Platform that comes with inbuilt functions and commands that play a vital role for debugging, editing and compiling the code in the environment.
- A range of Arduino modules available including Arduino Uno, Arduino Mega, Arduino Leonardo, Arduino Micro and many more.
- Each of them contains a microcontroller on the board that is actually programmed and accepts the information in the form of code.

- The main code, also known as a sketch, created on the IDE platform will ultimately generate a Hex File which is then transferred and uploaded in the controller on the board.
- The IDE environment mainly contains two basic parts: Editor and Compiler where former is used for writing the required code and later is used for compiling and uploading the code into the given Arduino Module.
- This environment supports both C and C++ languages.

4.3 The Arduino IDE system

The IDE environment is mainly distributed into three sections

- Menu Bar
- Text Editor
- Output Pane

4.3.1 Menu Bar

The bar appearing on the top is called **Menu Bar** that comes with five different options as follow

- **File** – You can open a new window for writing the code or open an existing one. Following table shows the number of further subdivisions the file option is categorized into.

As you go to the preference section and check the compilation section, the Output Pane will show the code compilation as you click the upload button.

And at the end of compilation, it will show you the hex file it has generated for the recent sketch that will send to the Arduino Board for the specific task you aim to achieve.

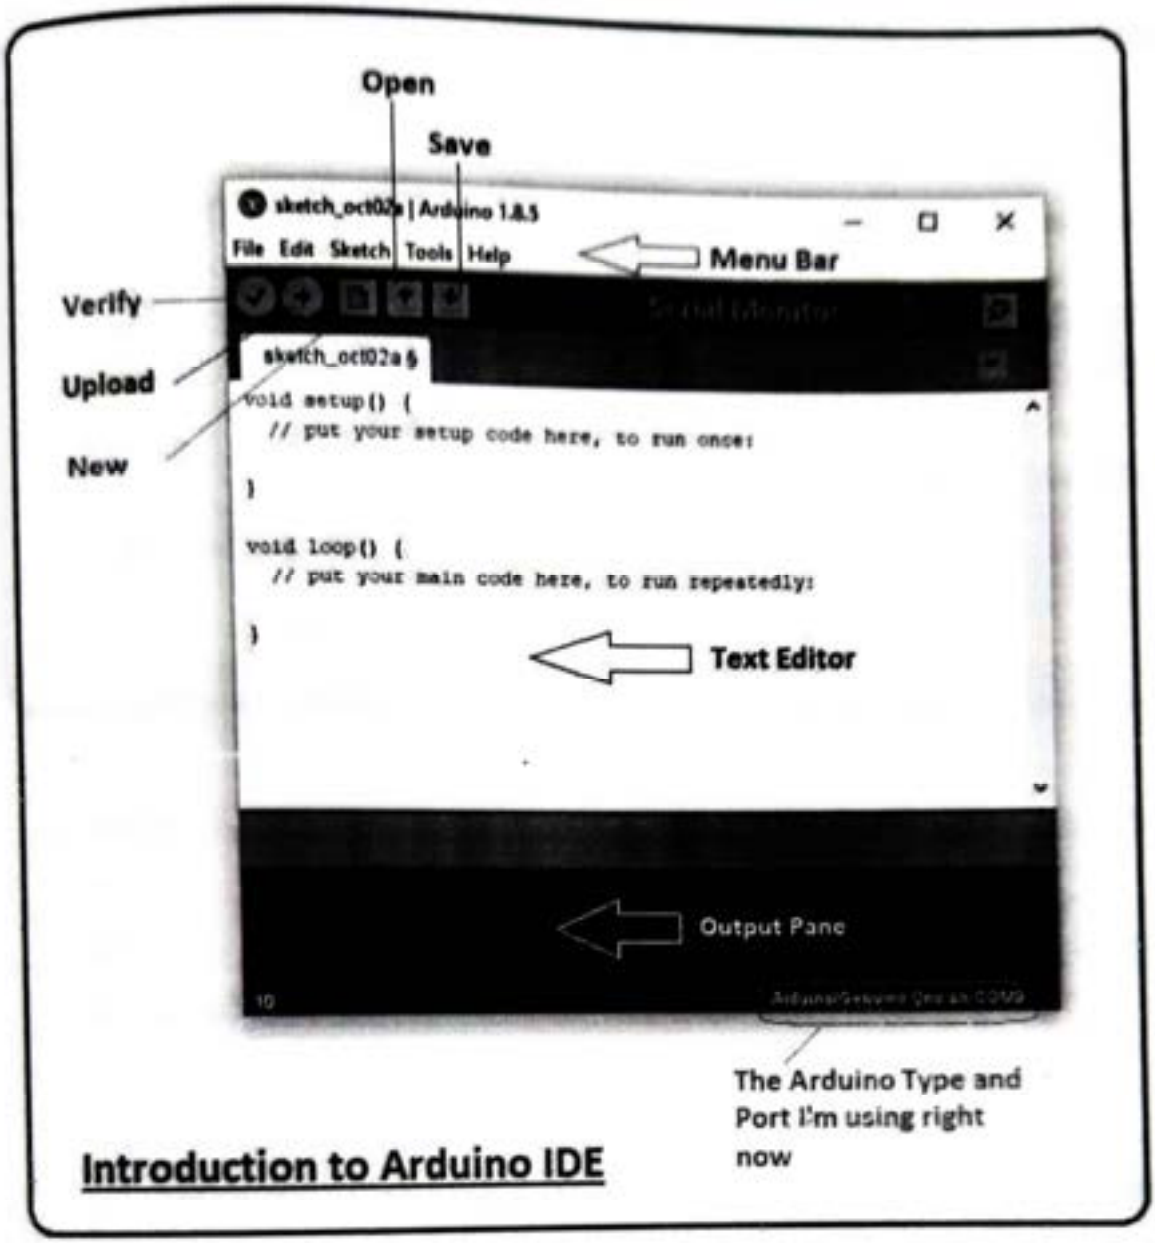

Fig 4.1 Introduction to Ardino IDE

4.3.2 Text Editor

- Edit – Used for copying and pasting the code with further modification for font
- Sketch – For compiling and programming
- Tools – Mainly used for testing projects. The Programmer section in this panel is used for burning a bootloader to the new microcontroller.
- Help – In case you are feeling skeptical about software, complete help is available from getting started to troubleshooting.

The Six Buttons appearing under the Menu tab are connected with the running program as follow.

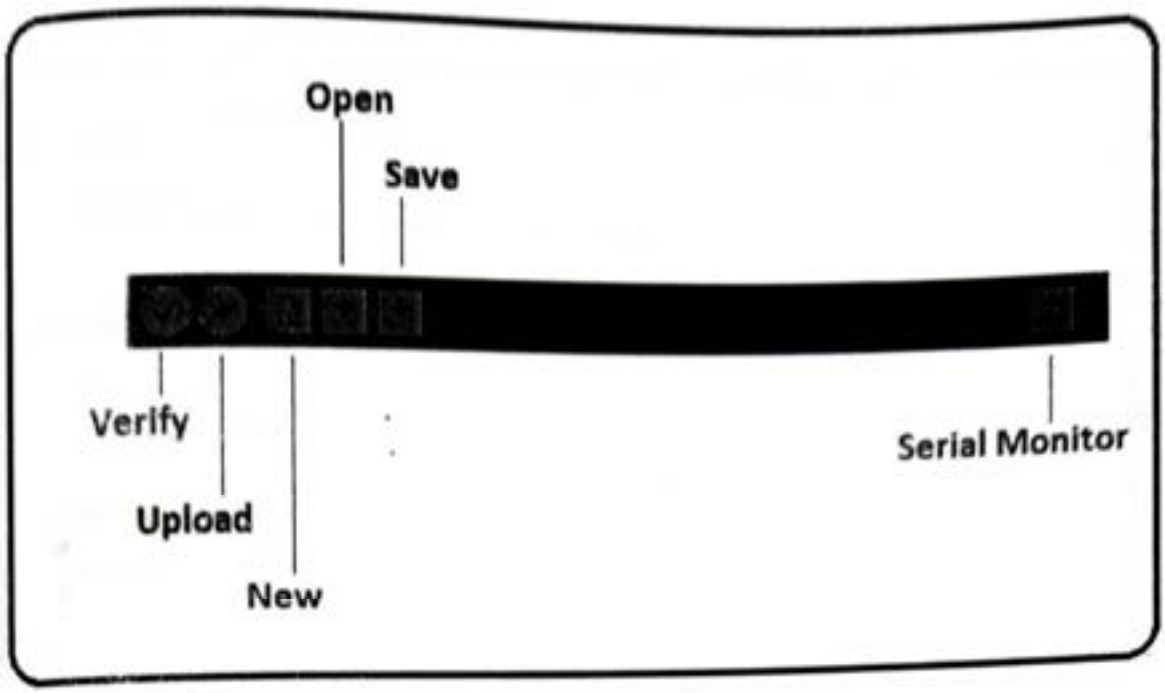

Fig 4.2 Editor Tool

- The check mark appearing in the circular button is used to verify the code. Click this once you have written your code.
- The arrow key will upload and transfer the required code to the Arduino board.
- The dotted paper is used for creating a new file.
- The upward arrow is reserved for opening an existing Arduino project.
- The downward arrow is used to save the current running code.
- The button appearing on the top right corner is a Serial Monitor – A separate pop-up window that acts as an independent terminal and plays a vital role for sending and receiving the Serial Data. You can also go to the Tools panel and select Serial Monitor, or pressing Ctrl+Shift+M all at once will open it instantly. The Serial Monitor will actually help to debug the written Sketches where you can get a hold of how your program is operating. Your Arduino Module should be connected to your computer by USB cable in order to activate the Serial Monitor.
- You need to select the baud rate of the Arduino Board you are using right now. For my Arduino Uno Baud Rate is 9600, as you write the following code and click the Serial Monitor, the output will show as the image below.

The main screen below the Menu bard is known as a simple text editor used for writing the required code.

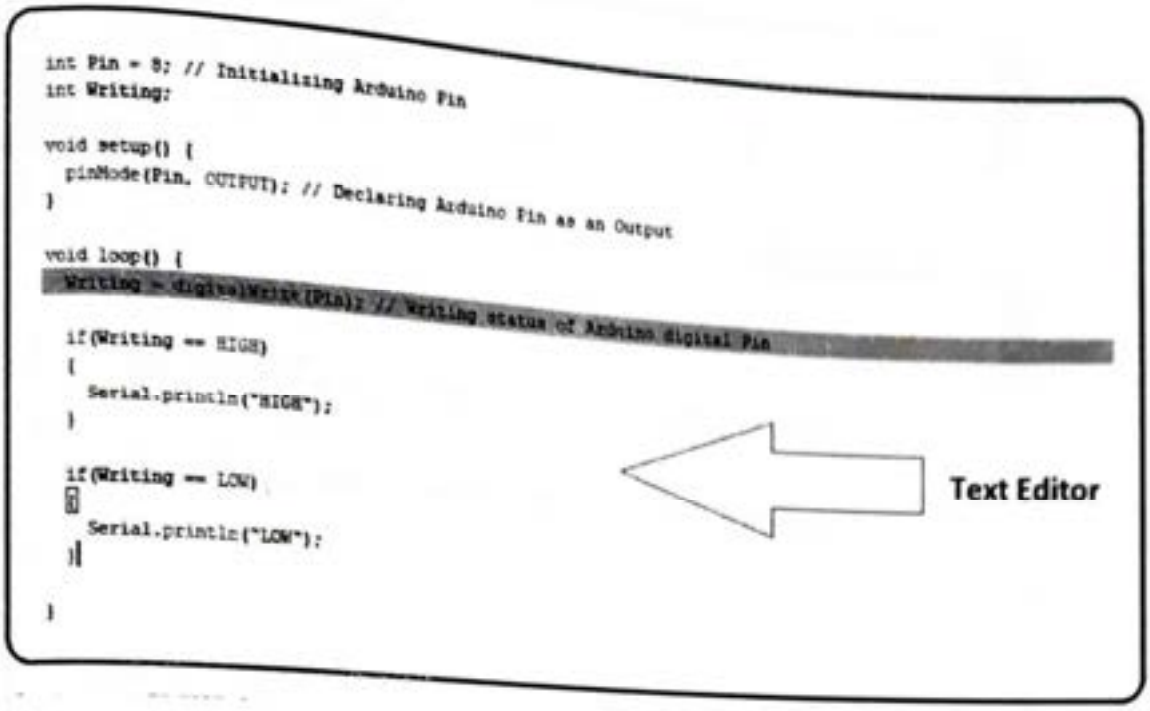

Fig 4.3 Text Editor Window

The bottom of the main screen is described as an Output Pane that mainly highlights the compilation status of the running code: the memory used by the code, and errors occurred in the program. You need to fix those errors before you intend to upload the hex file into your Arduino Module.

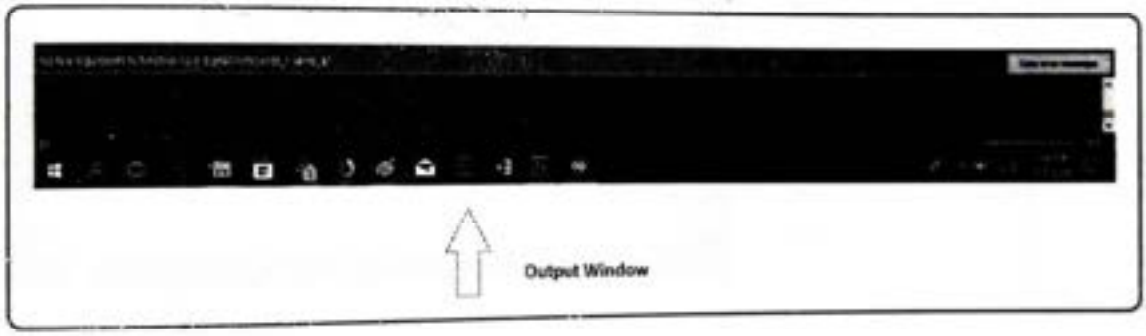

Fig 4.4 Output Window

More or less, Arduino C language works similar to the regular C language used for any embedded system microcontroller, however, there are some dedicated libraries used for calling and executing specific functions on the board.

4.4 Libraries

Libraries are very useful for adding the extra functionality into the Arduino Module. There is a list of libraries you can add by clicking the Sketch button in the menu bar and going to Include Library.

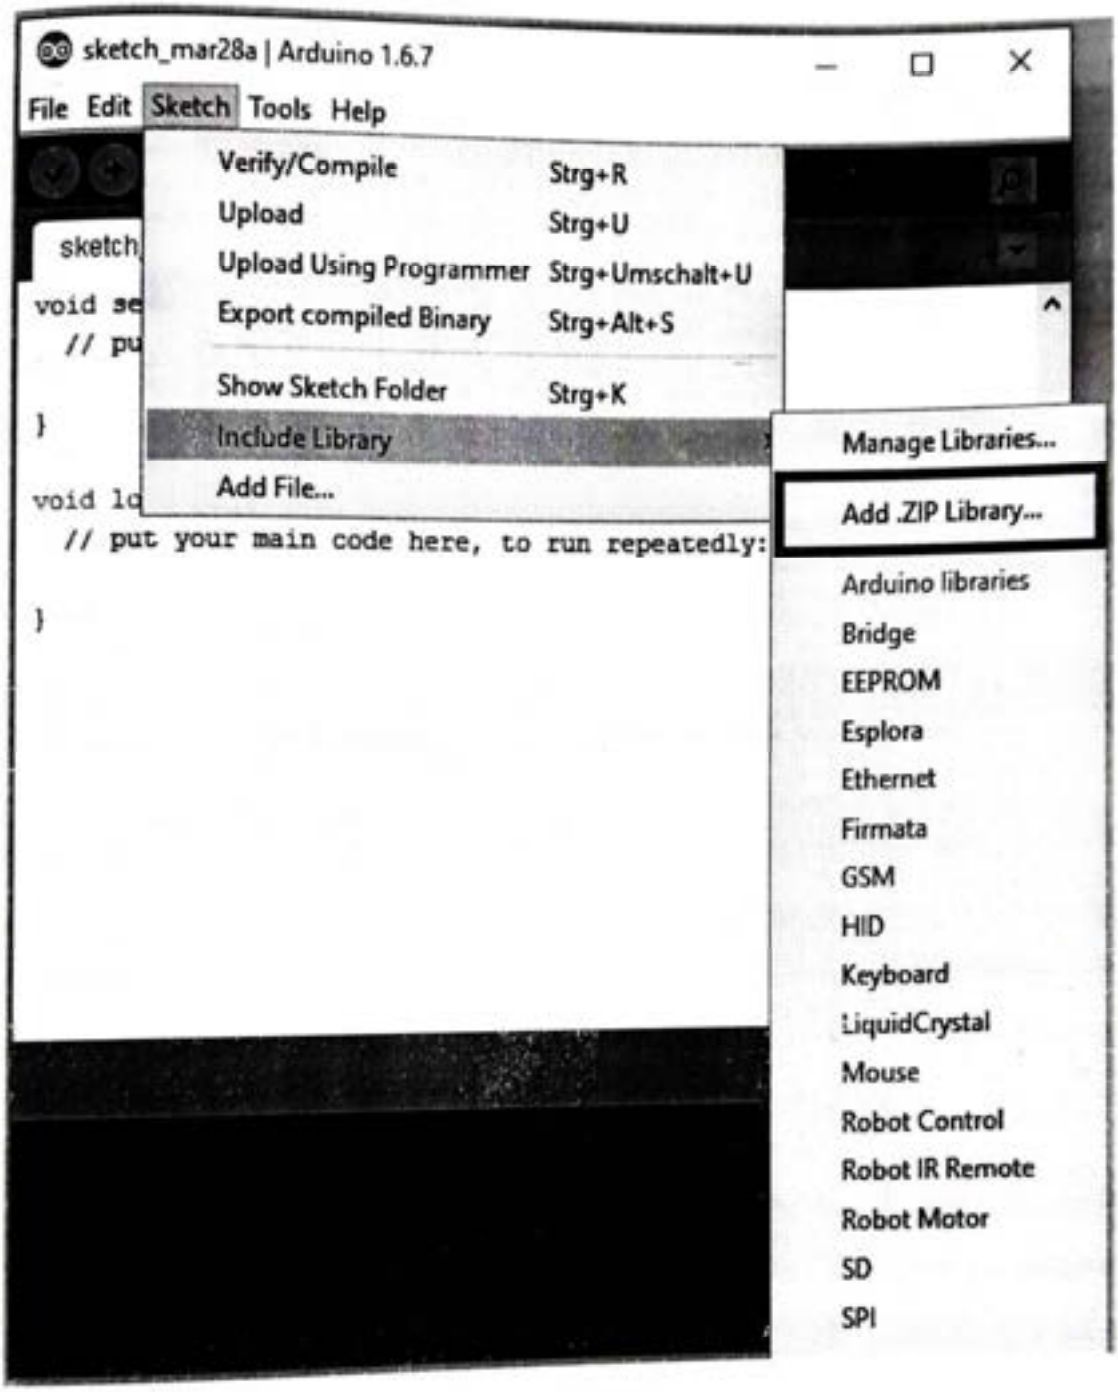

Fig 4.5 Library Window

4.5 Making Pins Input or Output

The digital Read and digital write commands are used for addressing and making the Arduino pins as an input and output respectively.

4.6 Selection of Boards

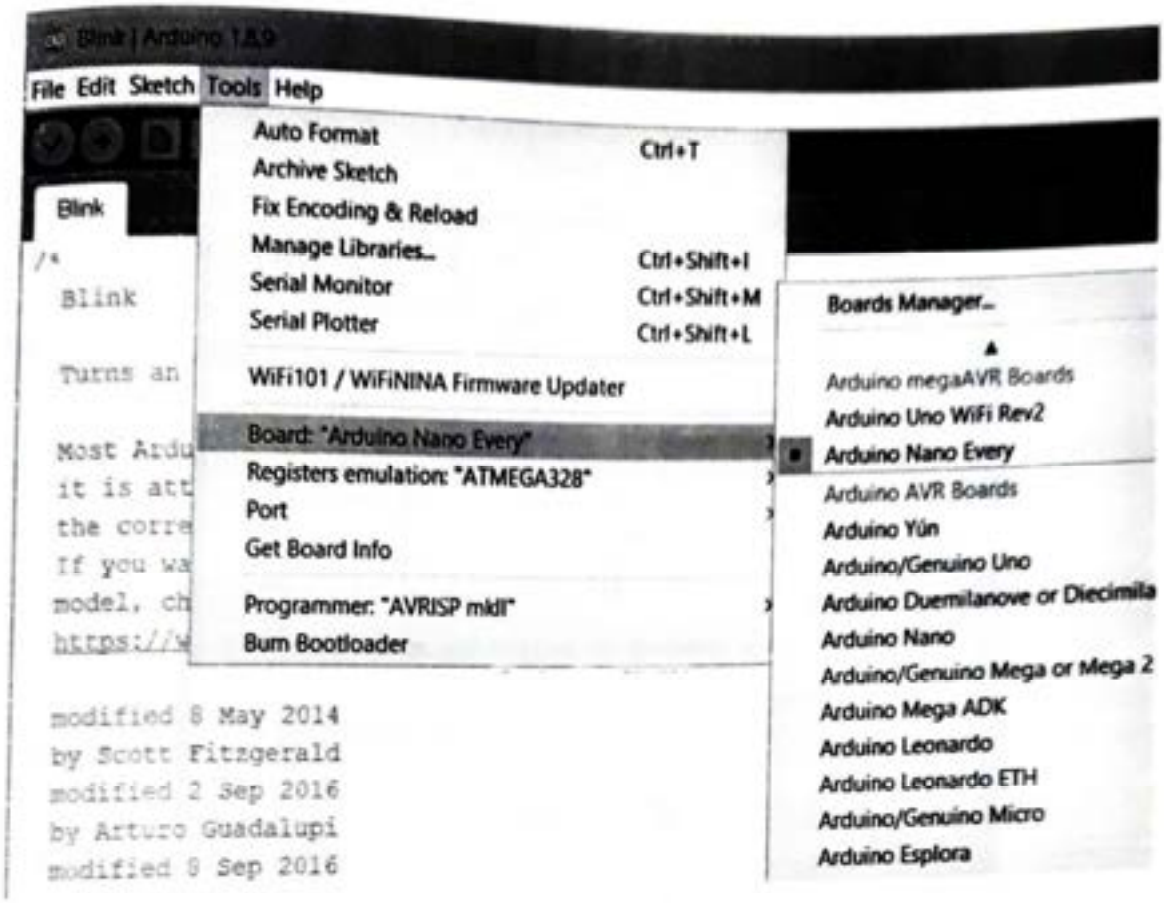

Fig 4.6 Selection of Board Window

- Just go to the "Board" section and select the board you aim to work on. Similarly, COM1, COM2, COM4, COM5, COM7 or higher are reserved for the serial and USB board. You can look for the USB serial device in the ports section of the Windows Device Manager.

Following figure shows the COM4 that I have used for my project, indicating the Arduino Uno with COM4 port at the right bottom corner of the screen.

- After correct selection of both Board and Serial Port, click the verify and then upload button appearing in the upper left corner of the six button section or you can go to the Sketch section and press verify/compile and then upload.
- The sketch is written in the text editor and is then saved with the file extension.ino.

4.7 Bootloader

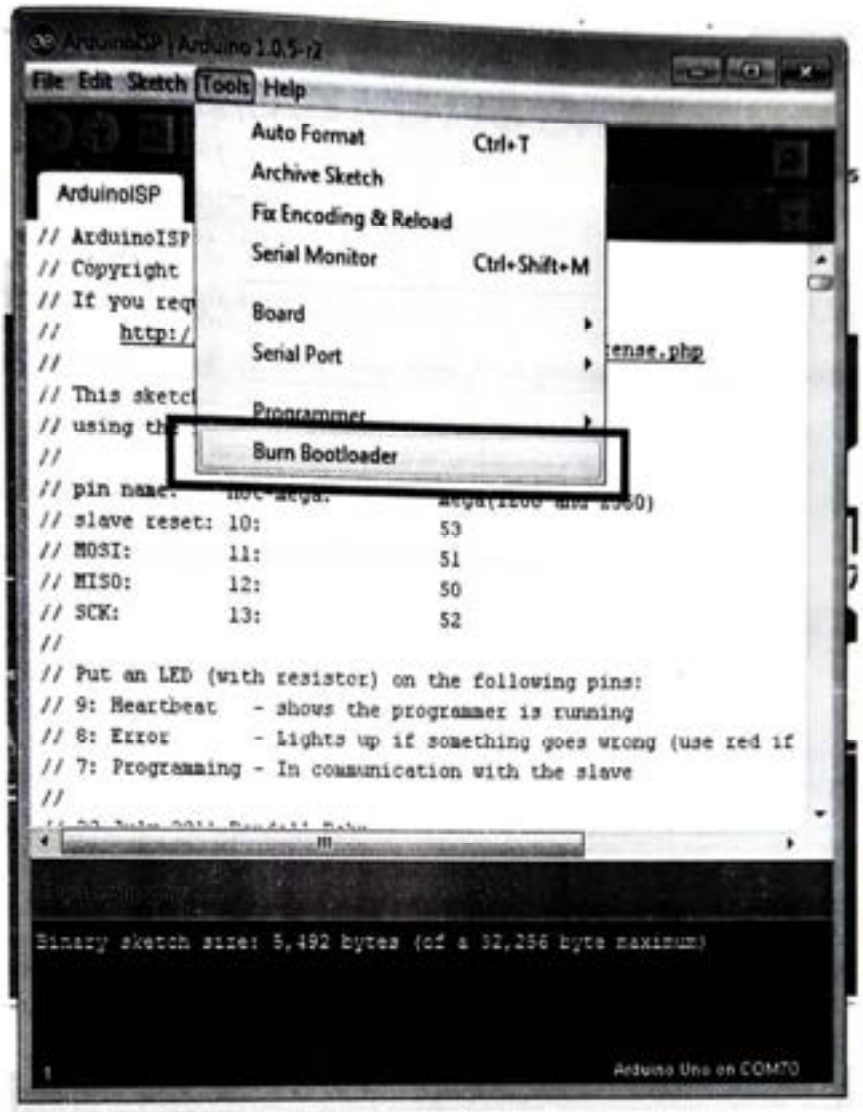

Fig 4.7 Bootloader Window

As you go to the Tools section, you will find a bootloader at the end. It is very helpful to burn the code directly into the controller, setting you free from buying the external burner to burn the required code.

When you buy the new Arduino Module, the bootloader is already installed inside the controller. However, if you intend to buy a controller and put in the Arduino module, you need to burn the bootloader again inside the controller by going to the Tools section and selecting the burn bootloader.

CHAPTER 5

RESULTS AND DISCUSSION

The design and implementation of large-scale and long-term CO2 monitoring sensor network is discussed. A low-cost sensor deployment strategy with guaranteed performance which addresses the sensor deployment problems in the existing models has been proposed. Hardware implementation of this model has been done and the parameters are periodically monitored with few sensors.

CHAPTER 6

WORK HAS TO BE DONE IN PHASE II

For this project in phase II, we are going to implement cyber-physical system that controls environmental circumstances or environmental conditions in distant places in indoor areas. Software tools like Arduino IDE, PHP used for cyber system design. In phase II hardware kit is placed for model.

ABSTRACT

In our project Arduino based automatic vehicle engine locking with location tracking system. We hear lot of accidents due to drunken driving. Drunken drivers will not be in stable condition and so rash driving causes inconvenience for other road users. In this project we are developing an Automatic engine lock system.We are introducing a system that will detect drunken driver through alcoholic sensor through fitted on the steering .The controller keeps looking for the output from these sensors. If there are any traces of alcohol above the set limit, then the system will lock the engine. GPS and GSM are used to track the location and the system sends an alert to the owner on his mobile phone or mail as a short message (SMS). By implementing this system in vehicle, a safe journey is possible which would decrease the injuries during accident also reduce the accident rate. Additional features such as mobile call detector and vibration sensor are also included. Mobile call detector is used to detect the incoming and outgoing calls, SMS and video, etc.., and vibration sensor is used for the indication of accident to the police/ambulance.

CHAPTER 1

INTRODUCTION

Now-a-days, many accidents are happening because of the alcohol consumption of the driver or the person who is driving the vehicle. Thus drunk driving is a major reason of accidents in almost all countries all over the world. In this system consists of hardware components are Arduino Uno board, MQ6 Alcohol sensor, Vibrating sensor, Mobile phone detector. GSM and GPS module. The MQ-6alcoholsensor is used to sense the liquor detection and the system detects the presence of alcohol in the vehicle and immediately locks the engine of the vehicle. At the same time an SMS along with the location of the vehicle is send to the owner of the four wheelers. Additional features such as mobile call detector and vibration sensor are also included. Mobile call detector is used to detect the incoming and outgoing calls, SMS and video, etc.., and vibration sensor is used for the indication of accident to the police/ambulance. Government must enforce laws to install such circuit in every four wheelers and must regulate all four wheelers companies to pre install such mechanisms while manufacturing the four wheelers itself. If this is achieved the deaths due to drunken drivers can be brought to minimum level.

CHAPTER 2

LITERATURE SURVEY

.1 Alcohol Detection and Motor Locking System

International journal of advanced research in electrical, electronics and nstrumentation engineering- vol. 6, issue 2, February 2017

:.1.1 Introduction

Every hour, 40 people which beneath the age of 25 die in highway accidents. And as according to the world fitness organization, road traffic accidents caused an about 1.24 million deaths international within the yr. 2010, slightly down from 1.26 million in 2000. That is one person is died for every 25 seconds. Only 28 international locations, representing 449 million people (7% of the world's population), have well enough legal guidelines that cope with all five danger elements (pace, drink–using, helmets, seat-belts and toddler restraints). Over a third part of street site visitors dying are in low- and middle-earnings countries are among pedestrians and cyclists. However, less than 35% of low and center earnings nations have regulations in area to guard those road users .The important aim of this device is to keep away from the fee accidents which can be usually occurred due to drunkenness of driving force. This device stumble on the drunkenness of driving force and save you them from riding, so this attempt to provide one form of security or protection mechanism to driving force and save stay. There also are lot of coincidence purpose together with excessive pace of automobile, drunken, drowsiness of driver, seat belt adjustment, and keep away from the use helmet that's all cause twist of fate.

2.1.2 Microcontroller AT89C51

Now let us talk about this popular 8051 chip. It has on chip ROM in the form of flash memory. This is ideal for fast development since flash memory can be erased in seconds compared to the twenty minutes or more needed for the 8751. For this reason the AT89C51 is

used in place of the 8751 to eliminate the waiting time needed to erase the chip and thereby speed up the development time. To use the AT89C51 to develop a microcontroller-based system requires a ROM burner that supports flash memory; however, a ROM eraser is not needed. Notice that in flash memory you must erase the entire contents of ROM in order to program it again. This erasing of flash is done by the PROM burner itself.

2.1.3 Result

Our system efficiently checks the accidents occurs or not and drunken driving. By implementing this system in vehicle, a safe journey is possible which would decrease the injuries during accidents and also reduce the accident rate due to drunken driving.

2.1.4 Drawback

The drawback is that it cannot detect the location of vehicle.

2.2 Automatic Engine Locking System through Alcohol Detection in Arduino Using IOT

International Research Journal of Engineering and Technology (IRJET)
www.irjet.net p-ISSN: 2395-0072

2.2.1 Introduction

We hear lot of accidents due to drunk driving and it will not be in stable condition. So it rash driving is the in convenience for other road death for the drunk driver and not for others. In this system uses a compact Arduino Uno board. Programs are developed in embedded C. The main purpose for this project is "Automatic Engine Locking System through Alcohol Detection using Arduino". Most of these days many accidents are happening became of the alcohol detection of the driver or the person who is in the vehicle. Almost all the countries in the world are facing major accidents because of Drunk & Drive. In this project is designed for safety of the people seating the vehicle.

2.2.2 MQ-3 Alcohol sensor

This alcohol sensor is appropriate for distinguishing liquor fixation on your breath, much the same as your normal Breathalyzer. It has a high affectability and quick reaction time. Sensor gives a simple resistive yield in view of liquor fixation. The drive circuit is extremely straight forward; all it needs is one resistor. A basic interface could be a 0-3.3V ADC.

2.2.3 Result

An effective solution is provided to develop the intelligent system for vehicles which will monitor various parameters of vehicle in between constant time period and will sent data to the concerned persons. This is done by using platforms like Arduino, Sensor, DC motor, LCD display.

2.2.4 Drawback

The location of the vehicle cannot be found.

2.3Arduino Based Automatic Engine Locking System for Drunken Drivers.

International journal of innovative research in science, engineering and technology, www.irjet.net p-ISSN: 2395-0072

2.3.1 Introduction

Now-a-days, many accidents are happening because of the alcohol consumption of the driver or the person who is driving the vehicle. Drunk driving is a major reason of accidents in almost all countries all over the world. Alcohol Detector in Car project is designed for the safety of the people seating inside the car. This project should be fitted / installed inside the vehicle. By implementing this design a safe car journey is possible and also drunken drivers can be controlled. Government must enforce laws to install such circuit in every car and must regulate all car companies to preinstall such mechanisms while manufacturing the car itself. If this is achieved the deaths due to drunken drivers can be brought to minimum level. In this

type of system, future scope can be safely landing of car aside without disturbing other vehicles. India had earned the dubious distinction of having more number of fatalities due to road accidents in the world. Road safety is emerging as a major social concern around the world especially in India. Drinking and driving is already a serious public health problem, which is likely to emerge as one of the most significant problems in the near future. The system implemented by us aims at reducing the road accidents in the near future due to drunken driving. The system detects the presence of alcohol in the vehicle and immediately locks the engine of the vehicle. At the same time an SMS along with the location of the vehicle is send to three pre-selected contacts. Future scope of this system is to control the accidents and providing useful details about the accidental vehicle, thereby reducing the rate of accidents taking place due to drunken driving.

2.3.2 Arduino Uno Board

Arduino UNO R3 is a open source micro controller board based on the ATmega 328 chip. This board has 14 digital input/output pins,6analog input pins, Onboard 16 MHZ ceramic resonator, Port for USB connection, Onboard DC power jack, An ICSP header and a micro controller reset button.

2.3.3 Result

In this project we have developed a real time model that can automatically lock the engine when a drunken driver tries to drive a car. By fitting this alcohol sensor into the car, we can save guard the life of the driver and also the remaining passengers.

2.3.4 Drawback

The drawback is, it cannot track the position clearly.

2.4 Automatic Vehicle Accident Detection and Messaging System Using GSM and GPS Modem

International Journal of Advanced Research in Electrical, Electronics and Instrumentation Engineering-Vol. 3, Issue 7, July 2014.

2.4.1 Introduction

The high demand of automobiles has also increased the traffic hazards and the road accidents. Life of the people is under high risk. This is because of the lack of best emergency facilities available in our country. An automatic alarm device for vehicle accidents is introduced in this paper. This design is a system which can detect accidents in significantly less time and sends the basic information to first aid centerwithin a few seconds covering geographical coordinates, the time and angle in which a vehicle accident had occurred. This alert message is sent to the rescue team in a short time, which will help in saving the valuable lives. A Switch is also provided in order to terminate the sending of a message in rare case where there is no casualty, this can save the precious time of the medical rescue team. When the accident occurs the alert message is sent automatically to the rescue team and to the police station. The message is sent through the GSM module and the location of the accident is detected with the help of the GPS module. The accident can be detected precisely with the help of both Micro electro mechanical system (MEMS) sensor and vibration sensor. The Angle of the rolls over of the car can also be known by the message through the MEMS sensor. This application provides the optimum solution to poor emergency facilities provided to the roads accidents in the most feasible way.

2.4.2 GSM & GPS Module

GSM is used as a media which is used to control and monitor the transformer load from anywhere by sending a message. It has its own deterministic character. It is also highly economic and less expensive; hence GSM is preferred most for this mode of controlling.GPS is used in vehicles for both tracking and navigation. Tracking systems enable a base station to keep track of the vehicles without the intervention of the driver where, as navigation system

helps the driver to reach the destination. When an accident occurred in any place then GPS system tracks the position of the vehicle.

2.4.3 Result

The proposed Vehicle accident detection system can track geographical information automatically and sends an alert SMS regarding accident. Experimental work has been carried out carefully. The result shows that higher sensitivity and accuracy is indeed achieved using this project.

2.4.4 Drawback

It does not work without network.

2.5 Alcohol Sensing Alert - Engine Locking System by Using Internet of Things (IOT) Technology

International Journal of Technical Innovation in Modern Engineering& Science (IJTIMES)

2.5.1Introduction

Now a day's every system is automated in order to face new challenges. In the present days Automated systems have less manual operations, flexibility, reliability and accurate. Due to this demand every field prefers automated control systems. Especially in the field of electronics automated systems are giving good performance. We usually come across drink and driving cases where drunk drivers crash their cars under the influence of alcohol causing damage to property and life. So here we propose an innovative system to eliminate such cases. Our proposed system would be constantly monitoring the driver breath by placing it on the driver wheel or somewhere the driver's breath can be constantly monitored by it. So if a driver is drunk and tries to drive the system detects alcohol presence in his/her breathe and locks the

engine so that the vehicle fails to start. In another case if the driver is not drunk while he starts the vehicle and engine is started but he/she drinks while driving the sensor still detects alcohol in his breath and stops the engine so that the car would not accelerate any further and driver can steer it to roadside. In this system we use an AVR family microcontroller interfaced with an alcohol sensor along with an LCD screen and a dc motor to demonstrate the concept. So here the alcohol sensor is used to monitor uses breath and constantly sends signals to the microcontroller.

2.5.2 IoT

Internet of Things (IoT) is an eco-community of associated physical items that are available through the web. The 'thing' in IoT could be a man with a heart screen or a vehicle with worked in-sensors, i.e. objects that have been appointed an IP address and can gather and exchange information over a system without manual help or mediation.

2.5.3 Result

The "Ignition Interlock by Alcohol Breath Analyzer using IOT Technology" was designed such that the driver alcohol content is transmitted to the owner on his mobile phone as a short message (SMS) at his request. The microcontroller gets the information regarding the alcohol through the alcohol sensor.

2.5.4 Drawback

The main drawback is that the exact location cannot be detected and they may not work properly at sometimes.

2.6 Automatic Accident Detection and Alerting System Based on IOT

(International Journal of Innovative Research in Computer and Communication Engineering- An ISO 3297: 2007 Certified Organization)

2.6.1 Introduction

Transportation has great importance in our daily life and its development has made many of our chores much easy. But it can cause disaster to us and even can kill us through accidents. During 2008, Road Traffic Injuries ranked fourth among the leading causes of death in the world. Nearly 1.3 million people die every year on the world's roads and 20 to 50 million people suffer non-fatal injuries, with many sustaining a disability as a result of their injury. Road traffic injuries are the leading cause of death among young people aged 15-29 years and cost countries 1-3% of the gross domestic product (GDP). If no action is taken, road traffic crashes are predicted to result in the deaths of around 1.9 million People annually by 2020.The purpose of project is to find the vehicle where it is and locate the vehicle by means of sending location using a system which is placed inside of vehicle system. Most of the times we may not be able to find accident location because we don't know where accident will happen. In order to give treatment for injured people, first we need to know where the accident happened through location tracking and sending a message to your related one or to the emergency services.

2.6.2 Arduino Uno

The Arduino Uno is a microcontroller board based on the ATmega328. It has 14 digital input/output pins (of which 6 can be used as PWM outputs), 6 analog inputs, a 16 MHz ceramic resonator, a USB connection, a power jack, an ICSP header, and a reset button. It contains everything needed to support the microcontroller. Simply connect it to a computer with a USB cable or power it with an AC-to-DC adapter or battery to get started.

2.6.3 Result

The system provides the design which has the advantages of low cost, portability and small size. The platform of the system is IDE along with accelerometer sensor, GPS and GSM,

interfacing which reduces the alarm time to a large extent and locates the site of accident accurately.

2.6.4 Drawback

The great maintenance is requires at the track location.

2.7 Programmed Engine Locking System by Automatically Detecting Drunken Drivers.

International Journal of Innovative Research in Science, Engineering and Technology Vol. 4, Issue 11, November 2011

2.7.1 Introduction

The employments of installed frameworks are basically boundless, in light of the fact that consistently new items are acquainted with the business sector that uses inserted PCs in novel ways. As of late, equipment, for example, microprocessors, micro controllers, and FPGA chips have turned out to be much less expensive. So while actualizing another type of control, it's savvier to simply purchase the nonexclusive chip and compose your own custom programming for it. Creating a uniquely crafted chip to handle a specific errand or set of assignments expenses much additional time and cash. Numerous inserted PCs even accompany broad libraries, so that "written work your own particular programming" turns into an exceptionally insignificant undertaking to be sure. From a usage perspective, there is a noteworthy contrast between a PC and an inserted framework. Implanted frameworks are frequently required to give Real-Time reaction. The primary components that make implanted frameworks exceptional are its unwavering quality and straightforwardness in troubleshooting.

2.7.2 AT89S52 Microcontroller

The Intel 8052 is Harvard architecture, single chip microcontroller (µC) which was developed by Intel in 1987 for use in embedded systems. 8052 is an 8-bit processor, meaning that the CPU can work on only 8 bits of data at a time. Data larger than 8 bits has to be broken

into 8-bit pieces to be processed by the CPU. 8052 is available in different memory types such as UV-EPROM, Flash and NV-RAM.

2.7.3 Result

Coordinating elements of all the equipment parts utilized have been created as a part of it. Vicinity of each module has been contemplated out and set deliberately, in this manner adding to the best working of the unit.

2.7.4 Drawback

The drawback is that, it cannot detect the location of the vehicle.

2.8 Liquor Detection through Automatic Motor Locking System

2.8.1 Introduction

Now-a-days we hear about lot of accidents due to drunken driving. Drunken drivers will not be in stable condition and so the rash driving is the inconvenience for other road users and also question of life and death for the drunken drivers, also for others. In this project, we are developing an Auto Lock System. The input for the system is from Detection Sensors either from Alcohol Breath or any other mechanism. The controller keeps looking for the output from these sensors. If there are any traces of Alcohol above the set limit, then the system will lock the Engine. Here a simulating process is activated using a DC motor through the relay and the complete process is under the supervision of an intelligent AT89c51 microcontroller. Even though efficient set up of requirements have been adopted for the traditional methods it may not be sufficient and that much protective for such a complex method, whereas here in this process this could be a better idea of inserting the complete state of art design into the system.

2.8.2 MQ3 Alcohol Sensor

The alcohol sensor (MQ3) is efficient among all the other sensors with fast response, high sensitivity, stable life and also a simple drive circuit. In brief the sensitivity is always improved by the variable load resistor i.e the sensitivity is proportional to the resistor load.

2.8.3 Result

Finally after the design of system the input is identified by the sensor through the breathe of a human. In the next scenario the levels of alcohol is measured by the sensor and compared with the set-in limits. If the set limit of consumption in alcohol is less than the alcohol consumed by the person the system of activating relay is initiated which in turn activities the automatic lock on the vehicle i.e., stops the motor if it is in running state or it is unable to start.

2.8.4 Drawback

The location tracking is not possible.

2.9 Alcohol Detection System in Vehicle Using Arduino

International Research Journal of Engineering and Technology (IRJET)

Volume: 04 Issue: 06 | June -2017

2.9.1 Introduction

Drinking and driving is already a serious public health problem ,which is likely to merge as one of the most significant problems in near future .the system implemented by us ims at reducing the road accident in the near future due to drunken and drive . This paper resent the progress in using the alcohol detector ,a device that senses a change in the coholic gas content of the surrounding air these device is more commonly referred to as a

breath analysis, as it analysis the alcohol content from person's breath. The system detects the presence of alcohol in the vehicle and immediately locks the engine of the vehicle.

2.9.2 Arduino Board

The Arduino board is the central unit of the system. The Arduino Uno is the microcontroller board based on the ATmega 328. It is a programmable microcontroller for prototyping electromechanical devices. It has 14 digital inputs/output pins (of which 6 can be used as PWM output), 6 analog inputs, a 16 MHz ceramic resonators the arduino differs from all preceding board is that it does not use the FTDI USB to serial driver chip.

2.9.3 Result

We have provided a very effective solution to develop an intelligent system for vehicles for alcohol detection whose core is Arduino. Future scope of this system is to control the accidents causes due to alcohol consumption. This system improves the safety of human being. And hence providing the effective development in the automobile industry regarding to reduce the accidents.

2.9.4 Drawback

This system is not suitable for location tracking and it's only used for engine locking system.

2.10 Alcohol Detection and Vehicle Controlling

International Journal of Engineering Trends and Applications (IJETA)

– Volume 2 Issue 2, Mar-Apr 2015

2.10.1 Introduction

India had earned the dubious distinction of having more number of fatalities due to road accidents in the world. Road safety is emerging as a major social concern around the world especially in India. Drinking and driving is already a serious public health problem, which is likely to emerge as one of the most significant problems in the near future. The system implemented by us aims at reducing the road accidents in the near future due to drunken driving. The system detects the presence of alcohol in the vehicle and immediately locks the engine of the vehicle. At the same time an SMS along with the location of the vehicle is send to three pre-selected contacts. Hence the system reduces the quantum of road accidents and fatalities due to drunk driving in future.

2.10.2 Arduino Microcontroller Board

The Arduino board is the central unit of the system. The Arduino Uno is a microcontroller board based on the ATmega328. It is a programmable micro controller for prototyping electromechanical devices.

2.10.3 Result

An effective solution is provided to develop the intelligent system for vehicles which will monitor various parameters of vehicle in-between constant time period .The designed system would finish the function of communicating GPS, GSM and control of various parameters. Future scope of this system is to control the accidents and providing useful details about the accidental vehicle, thereby reducing the rate of accidents taking place due to drunken driving.

2.10.4 Drawback

It need more cost and more maintenances.

2.11 Summary of Literature Review

Table 2.1 Summary of literature review

S.NO.	Technique	Principle	Drawbacks
1	**Alcohol Detection and Motor Locking System**	They had use PIC 16876A controller, Alcohol sensor, LCD Display And Alarm system to notify driver only, Ignition system was immediately off when detected alcohol.	It does not work without network.
2	**Automatic Engine locking System Through Alcohol Detection in Arduino using IOT**	This system uses MQ3 alcohol sensor with arduino along with GSM module to send message notification for users numbers and LCD Display to identify the alcohol is detected or not and DC motor to sense by the alcohol and it automatically stop the motor.	The drawback is that it cannot detect the location of vehicle.
3	**Arduino Based Automatic Engine Locking System for Drunken Drivers**	The input for the system is from Detection Sensors either from Alcohol Breath or any other mechanism. The controller keeps looking for the output from these sensors. If there are any traces of Alcohol above the set limit, then the system will lock the Engine	The location of the vehicle cannot be found.

4	**Automatic Vehicle Accident Detection and Messaging System Using GSM and GPS Modem**	The vehicle accident detection system can track geographical information automatically and sends an alert SMS regarding accident	The drawback is, it cannot track the position clearly.
5	**Alcohol sensing alert-engine locking system by using internet of things (IOT) technology.**	The microcontroller on encountering high alcohol signal from the alcohol sensor displays alcohol detection note on LCD screen and also stops the dc motor to demonstrate as engine locking.	The main drawback is that the exact location cannot be detected and they may not work properly at sometimes.
6	**Automatic Accident Detection and Alerting System Based on IOT**	The purpose of the project is to find the vehicle where it is and locate the vehicle by means of sending a message using a system which is placed inside of vehicle system	The great maintenance is requires at the track location.

7	**Programmed Engine Locking System by Automatically Detecting Drunken Drivers**	The purpose of the project is to find the vehicle where it is and locate the vehicle by means of sending a message using a system which is placed inside of vehicle system using AT89S52 microcontroller programming.	The drawback is that, it cannot detect the location of the vehicle.
8	**Liquor Detection through Automatic Motor Locking System**	The microcontroller keeps looking for the output from these sensors. If there are any traces of Alcohol above the set limit, then the system will lock the Engine. Here a simulating process is activated using a DC motor through the relay and the complete process is under the supervision of an intelligent AT89c51 microcontroller.	The location tracking is not possible
9	**Alcohol Detection System in Vehicle Using Arduino**	This project using the alcohol detector ,a device that senses a change in the alcoholic gas content of the surrounding air these device is more commonly referred to as a breath analysis, as it analysis the alcohol content from person's breath. The system detects the presence of alcohol in the vehicle and immediately locks the engine of the vehicle.	This system is not suitable for location tracking and it's only used for engine locking.
10	**Alcohol Detection and Vehicle Controlling**	We propose the detection of alcohol using alcohol detector connected to Arduino such that when the level of alcohol crosses a permissible limit, the vehicle ignition system will turn off the present location.	It need more cost and more maintenances.

CHAPTER 3

THEORETICAL BACKGROUND

3.1 Introduction

These years, the cases of traffic accident caused by drunk driving have increased rapidly. More and more people have realized that the drunk driving does great harm to public security. It's time to develop a kind of system which can stop the drunk driving effectively. We try to develop this system which is available on every car.

This project should be fitted / installed inside the vehicle. By implementing this design a safe car journey is possible and also drunken drivers can be controlled. Government must enforce laws to install such circuit in every car and must regulate all car companies to preinstall such mechanisms while manufacturing the car itself. If this is achieved the deaths due to drunken drivers can be brought to minimum level. In this type of system, future scope can be safely landing of car aside without disturbing other vehicles. India had earned the dubious distinction of having more number of fatalities due to road accidents in the world. Road safety is emerging as a major social concern around the world especially in India.

Drinking and driving is already a serious public health problem, which is likely to emerge as one of the most significant problems in the near future. The system implemented by us aims at reducing the road accidents in the near future due to drunken driving. The system detects the presence of alcohol in the vehicle and immediately locks the engine of the vehicle. At the same time an SMS along with the location of the vehicle is send to three pre-selected contact.

3.2 Proposed System

Alcohol detection in vehicle system is continuously growing over years which could resolve drunken driving accidents worldwide. The Project Consists Arduino UNO board, MQ3-Alcohol Sensor, Buzzer, Rectifier Regulator, LCD Display, DC Motors, GSM Module &GPS Module. This project is used to sense the liquor detection using MQ3 Sensor and stop the running of dc motor using arduino programmer. Vehicle location will be traced using GPS and GSM module and send the location & message to the end user.

In this proposed system uses MQ3 alcohol sensor with arduino along with GSM module to send message notification for users numbers and LCD Display to identify the alcohol is detected or not and DC motor to sense by the alcohol and it automatically stop the motor. And the system check the permissible limit then the sensor will be triggered the processor about the respective voltage. Thus the system will automatically stop the motor and it send message to the users. Additional features such as mobile call detector and vibration sensor are also included. Mobile call detector is used to detect the incoming and outgoing calls, SMS and video, etc.., and vibration sensor is used for the indication of accident to the police/ambulance.

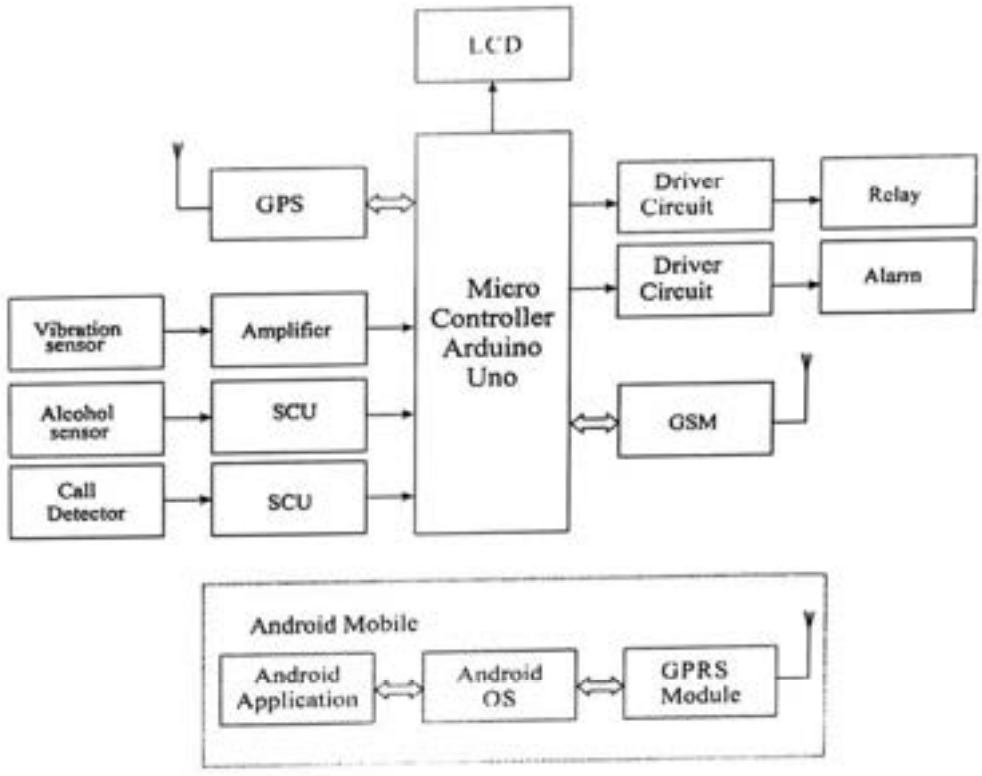

Figure 3.1 Block diagram of Liquor detection& Automatic Engine locking System

3.2.1 Arduino UNO board

The Arduino Uno is a microcontroller board based on the ATmega328. It has 14 digital input/output pins (of which 6 can be used as PWM outputs), 6 analog inputs, a 16 MHz ceramic resonator, a USB connection, a power jack, an ICSP header, and a reset button. It contains everything needed to support the microcontroller. Simply connect it to a computer with a USB cable or power it with an AC-to-DC adapter or battery to get started.

3.2.2 MQ-6 Alcohol Sensor

Sensitive material of MQ-6gas sensor is SnO2, which with lower conductivity in clean air. When the target flammable gas exist, the sensor's conductivity gets higher along with the gas concentration rising. MQ-6gas sensor can detect kinds of flammable gases, especially has high sensitivity to LPG (propane). It is a kind of low-cost sensor for many applications.

3.2.3 GSM Module

Global System for Mobile Communication is used as a media which is used to control and monitor the transformer load from anywhere by sending a message. It has its own deterministic character. Thereby, here GSM is used to monitor and control the DC motor, Vibrating sensor, Alcohol sensor and Mobile call detector by sending a message through GSM modem.

3.2.4 GPS Module

Global Positioning System is used in vehicles for both tracking and navigation. When an accident occurred in any place then GPS system tracks the position of the vehicle and sends the information to the particular person through GSM by alerting the person through SMS or by a call.

3.2.5 DC Motors

A motor is an electrical machine which converts electrical energy into mechanical energy. The principle of working of a DC motor is that "whenever a current carrying conductor is placed in a uniform magnetic field, it experiences a mechanical force ".

3.2.6 Motor Driver

A driver is an electrical circuit or other electronic component used to control another circuit or other component, such as a high-power transistor.

3.2.7 LCD Display

LCD (Liquid Crystal Display) screen is an electronic display module and find a wide range of applications. A 16x2 LCD display is very basic module and is very commonly used in various devices and circuits. A 16x2 LCD means it can display 16 characters per line and there are 2 such line.

3.2.8 Regulator

A voltage regulator is used to produce a constant linear output voltage. It's generally used with AC to DC power supply. And also it can be used as well as a DC to DC voltage convertor.

3.2.9 Rectifier

Rectifier is converted into Ac into pulsating Dc. A rectifier is an electrical device that converts alternating current (AC), which periodically reverses direction, to direct current (DC), which flows in only one direction.

3.2.10 Buzzer

A Buzzer or beeper is an audio signaling device. It may be A mechanical, electro mechanical, magnetic, electromagnetic, electro–acoustic or piezoelectric audio signaling device. A click, beep or ring can indicate that a button has been pressed.

3.2.11 Power supply

Rechargeable battery, storage battery, secondary cell or accumulator is a type of electrical battery which can be charged, discharged into load and recharged many times.

3.2.12 Vibration Sensor

A piezoelectric sensor is a device that uses the piezoelectric effect to measure pressure, acceleration, strain or force by converting them to an electrical signal.

3.2.13 Mobile Call Detector

It is also useful for detecting the use of mobile phone for spying and un-authorized video transmission. This must detect the incoming and outgoing calls, SMS and video transmission even if the mobile phone is kept in the silent mode.

3.2.14 Water Valve

A solenoid valve is an electro mechanical valve for use with liquid or gas controlled by running or stopping an electrical current through a solenoid, which is a coil of wire, thus changing the state of the valve.

CHAPTER 4

SYSTEM SPECIFICATION

4.1 Hardware Requirements

- Arduino UNO board
- MQ6-Alcohol Sensor
- Buzzer
- Rectifier
- Regulator
- LCD Display
- DC Motors
- GSM Module
- GPS Module
- Water valve
- Driver circuit
- Vibrating Sensor
- Mobile call detector
- Power Supply

4.1 Hardware Requirements

4.1.1 Arduino UNO board

The Arduino board is the central unit of the system.

Introduction:

The Arduino Uno is a microcontroller board based on the ATmega328. It is a programmable micro controller for prototyping electromechanical devices. You can connect Digital and Analog electronic signals:

- Sensors (Gyroscopes, GPS Locators, accelerometers)
- Actuators (LEDS or electrical motors)

It has 14 digital Input / output pins (of which 6 can be used as PWM outputs), 6 analog inputs, a 16 MHz ceramic Resonator, a USB connection, a power jack, an ICSP header and a reset button as shown in figure 2. It contains everything needed to support the microcontroller; simply connect it to a computer with a USB cable or power it with an AC-to-DC adapter or battery to get started.

The Uno differs from all preceding boards in that it does not use the FTDI USB-to-serial driver chip. Instead, it features the Atmega16U2 (Atmega8U2 up to version R2) programmed.

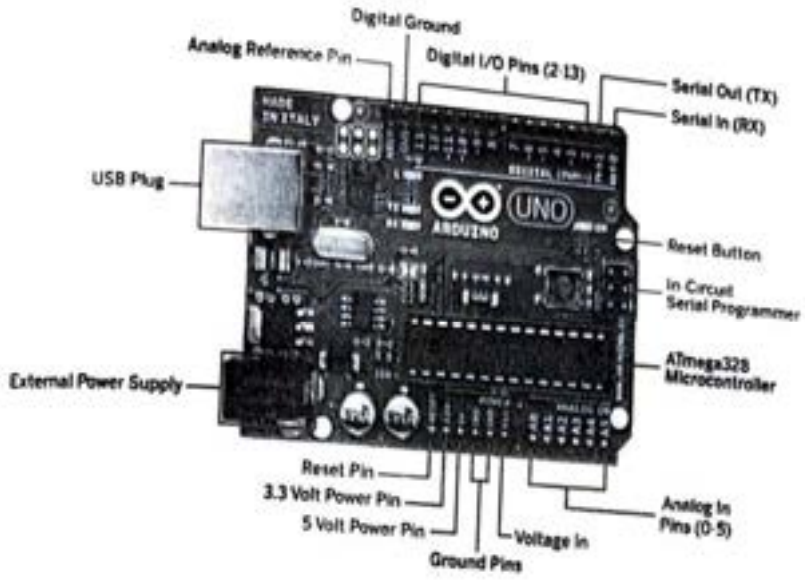

Figure4.1 Arduino Board Description

Arduino Uno is a microcontroller board based on the ATmega328P. It has 14 digital input/output pins (of which 6 can be used as PWM outputs), 6 analog inputs, a 16 MHz quartz crystal, a USB connection, a power jack, an ICSP header and a reset button. It contains everything needed to support the microcontroller; simply connect it to a computer with a USB cable or power it with an AC-to-DC adapter or battery to get started. You can tinker with your UNO without worrying too much about doing something wrong, worst case scenario you can replace the chip for a few dollars and start over again.

"Uno" means one in Italian and was chosen to mark the release of Arduino Software (IDE) 1.0. The Uno board and version 1.0 of Arduino Software (IDE) were the reference versions of Arduino, now evolved to newer releases. The Uno board is the first in a series of USB Arduino boards, and the reference model for the Arduino platform; for an extensive list of current, past or outdated boards see the Arduino index of boards.

Figure4.2 Arduino Board

Getting Started

You can find in the Getting Started section all the information you need to configure your board, use the Arduino Software (IDE), and start tinker with coding and electronics.

Technical specs

TABLE 4.1 Arduino Board Features

Microcontroller	ATmega328P
Operating Voltage	5V
Input Voltage (recommended)	7-12V
Input Voltage (limit)	6-20V
Digital I/O Pins	14 (of which 6 provide PWM output)
PWM Digital I/O Pins	6
Analog Input Pins	6
DC Current per I/O Pin	20 mA
DC Current for 3.3V Pin	50 mA
Flash Memory	32 KB (ATmega328P)

SRAM	of which 0.5 KB used by bootloader
EEPROM	2 KB (ATmega328P)
Clock Speed	1 KB (ATmega328P)
Length	16 MHz

4.1.2 Alcohol Sensor MQ-6

Sensitive material of MQ-6gas sensor is SnO2, which with lower conductivity in clean air. When the target flammable gas exist, the sensor's conductivity gets higher along with the gas concentration rising. Users can convert the change of conductivityto correspond output signal of gas concentrationthrough a simple circuit.MQ-6gas sensor can detect kinds of flammable gases, especially has high sensitivitytoLPG (propane). It is a kind of low-cost sensor for many applications.

Features

- High sensitivity to LPG, iso-butane, propane
- Small sensitivity to alcohol, smoke.
- Fast response.
- Stable and long life
- Simple drive circuit

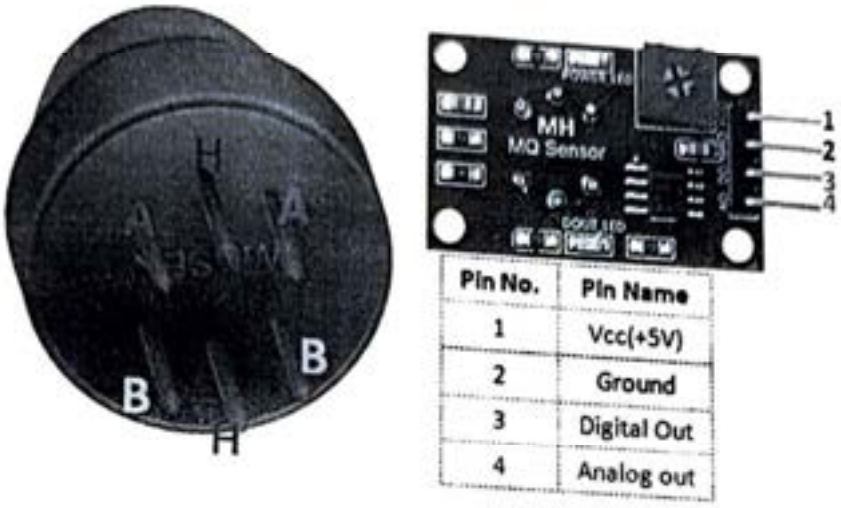
Sensitivity Adjustment

Resistance value of MQ-6 is difference to various kinds and various concentration gases. So, when using this components, sensitivity adjustment is very necessary. we recommend that you calibrate the detector for1000ppm of LPG concentration in air and use value of Load resistance (RL) about 20KΩ(10KΩ to 47KΩ).When accurately measuring. the proper alarm point for the gas detector should be determined after considering the temperature and humidity influence.

TABLE 4.2 Alcohol Sensor MQ-6 Features

Model No.		MQ-6
Sensor Type		Semiconductor
Standard Encapsulation		Bakelite, Metal cap
Detection Gas		LPG
Concentration		300-10000ppm (propane)
circuit	Loop voltage	≤ 24V DC
	Heater voltage	5.0V ±0.1V AC or DC
	Load resistance	Adjustable
character	Heater resistance	26 Ω± 3Ω (Room Temp)
	Heater consumption	≤ 950 Mw
	Sensitivity	RS (in air)/RS (in 2000ppm C3H8) ≥5
	Output Voltage	2.5V-4.0V(in 2000ppm C3H8)
	Slope	≤ 0.6 (R3000ppm/R1000ppm C3H8)
condition	Temp. humidity	20°C±2°C; 55%± 5%RH
	Standard test circuit	VC:5.0V ±0.1V; VH:5.0V ±0.1V
	Pre heat time	over 48hours
	Fast response Time	<10s

Figure 4.3 MQ-6 Sensor



Pin No.	Pin Name
1	Vcc(+5V)
2	Ground
3	Digital Out
4	Analog out

Figure 4.4 MQ6-Gas Sensor Pin out

Application

They are used in gas leakage detecting equipment in family and industry, are suitable for detecting of LPG, iso-butane, propane, LPG, avoid the noise of alcohol and cooking fumes and cigarette smoke.

4.1.3 GSM Module

The GSM net used by cell phones provides a low cost, long range, wireless communication channel for applications that need connectivity rather than high data rates.

chinery such as industrial refrigerators and freezers, HVAC, vending machines, vehicle vice etc. could benefit from being connected to a GSM system.

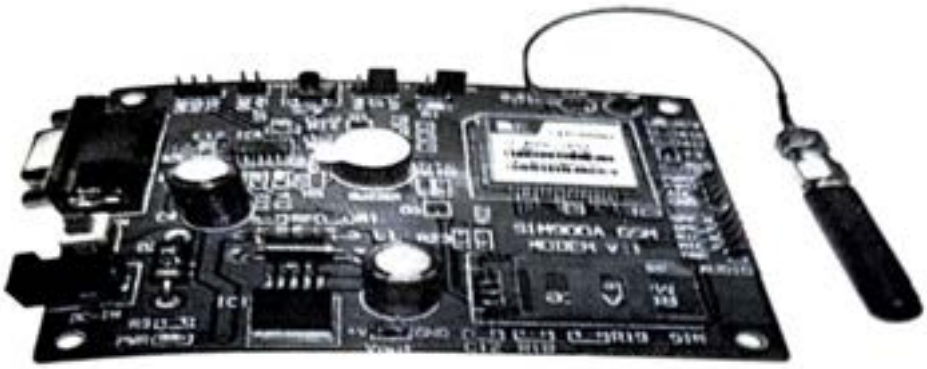


Figure 4.5 GSM Module

Take a given example. A garage offers a very special package to their customers. ased on the mechanics knowledge and the given vehicle, tailored service intervals can be ecified. A part of the service agreement is installation of a GSM modem in the vehicle. n on board service application can then notify the garage when the vehicle approaches s service interval. The garage will schedule an appointment and inform the customer.

The customer will benefit from a reliable and well-serviced vehicle at a minimum ost. The garage on the other hand can provide excellent customer support, vehicle atistics, efficient work scheduling, and minimum stocks.

This application note describes how to use an AVR to control a GSM modem in a ellular phone. The interface between modem and host is a textual protocol called Hayes T-Commands. These commands enable phone setup, dialing, text messaging and many uch features.

4.1.4 GPS Module

The Global Positioning System (GPS) is a space based satellite navigation system that provides location and time information in all weather conditions, anywhere on or near the Earth where there is an unobstructed line of sight to four or more GPS satellites. The system provides critical capabilities to military, civil and commercial users around the world. It is maintained by the United States government and is freely accessible to anyone with a GPS receiver.

Figure 4.6 GPS Module

TABLE 4.4 GPS module features

Chipset	SiRF Star III
Frequency	L1, 1575.42 MHz
C/A code	1.023 MHz chip rate
Channels	20 channel
Sensitivity	-159 dBm
Position	10 meters
Velocity	0.1 m/s

Time	1μs synchronized to GPS time
Default	WGS-84
Electrical level	0V ~ 2.85V RS-232
Baud rate	4,800 bps
Dimension	30mm*30mm*10.5mm ± 0.2mm
Operating temperature	-40°C to +85°C
Acceleration	Less than 4g
Main power input	4.5V ~ 6.5V DC
Power consumption	44mA
Reacquisition average	0.1 sec.,
Hot start average	1 sec.,

GPS devices may have capabilities such as:

- Maps, including streets maps, displayed in human readable format via text or in a graphical format turn-by turn navigation directions to a human in charge of a vehicle or vessel via text or speech.
- Directions fed directly to an autonomous vehicle such as a robotic probe.
- Traffic congestion maps (depicting either historical or real time data) and suggested alternative directions.
- Information on nearby amenities such as restaurants, fueling stations, and tourist attractions.

Figure 4.7 GPS Location tracking system

Other GPS devices need to be connected to a computer in order to work. This computer can be a home computer, laptop, PDA, digital camera, or smart phones. Depending on the type of computer and available connectors, connections can be made through a serial or USB cable, as well as Bluetooth, Compact Flash, SD, PCMCIA and the newer Express Card. Some PCMCIA/Express Card GPS units also include a wireless modem.

4.1.5 Liquid Crystal Display

Introduction

LCD (Liquid Crystal Display) screen is an electronic display module and find a wide range of applications. A 16x2 LCD display is very basic module and is very commonly used in various devices and circuits. These modules are preferred over seven segments and other multi segment LEDs. The reasons being: LCDs are economical; easily programmable; have no limitation of displaying special & even custom characters (unlike in seven segments), animations and so on. A 16x2 LCD means it can display 16 characters per line and there are 2 such lines. In this LCD each character is displayed in 5x7 pixel matrix. This LCD has two registers, namely, Command and Data.

Figure4.8 LCD Display

The command register stores the command instructions given to the LCD. A command is an instruction given to LCD to do a predefined task like initializing it, clearing its screen, setting the cursor position, controlling display etc. The data register stores the data to be displayed on the LCD. The data is the ASCII value of the character to be displayed on the LCD.

Features

- 5 x 8 dots with cursor
- + 5V power supply (Also available for + 3V)
- 1/16 duty cycle
- B/L to be driven by pin 1, pin 2 or pin 15, pin 16 or A.K (LED)
- N.V. optional for + 3V power supply

4.1.6 DC Motor

This DC or direct current motor works on the principal, when a current carrying conductor is placed in a magnetic field, it experiences a torque and has a tendency to move. This is known as motoring action. If the direction of current in the wire is reversed, the direction of rotation also reverses. When magnetic field and electric field interact they produce a mechanical force, and based on that the working principle of dc motor established. The direction of rotation of a this motor is given by Fleming's left hand rule,

which states that if the index finger, middle finger and thumb of your left hand are extended mutually perpendicular to each other and if the index finger represents the direction of magnetic field, middle finger indicates the direction of current, then the thumb represents the direction in which force is experienced by the shaft of the dc motor.

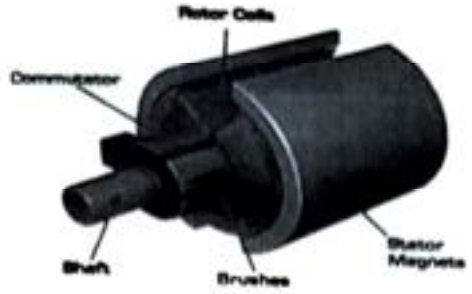

Figure 4.9 DC motor principle and construction

Structurally and construction wise a direct current motor is exactly similar to a DC generator, but electrically it is just the opposite. Here we unlike a generator we supply electrical energy to the input port and derive mechanical energy from the output port. We can represent it by the block diagram shown below.

Here in a DC motor, the supply voltage E and current I is given to the electrical port or the input port and we derive the mechanical output i.e. torque T and speed ω from the mechanical port or output port. The input and output port variables of the direct current motor are related by the parameter K.

$$T=KI \text{ and } E=Kw \quad \ldots\ldots\ldots 4.1$$

Figure4.10 Dc moto

4.1.7 Dc Motor Driver

In electronics, a driver is an electrical circuit or other electronic component used to control another circuit or other component, such as a high-power transistor. The term is used, for example, for a specialized computer chip that controls the high-power transistors in AC-to-DC voltage converters. An amplifier can also be considered the driver for loudspeakers, or a constant voltage circuit that keeps an attached component operating within a broad range of input voltages.

The following circuit will allow you to drive a 12V relay using logic voltage (an input of 4V or greater will trip the relay). The circuit has its own 12V power supply making itself contained but the power supply portion can be left out if an external supply will be used. The circuit shows an output from the power supply that can be used to power other devices but it should be noted that the supply is unregulated and not particularly powerful with the parts stated. The 12V DC output is suitable for powering a few LEDs or low voltage lights but should not be used to power other electronic boards or motors.

Using Transistor

Single direction control

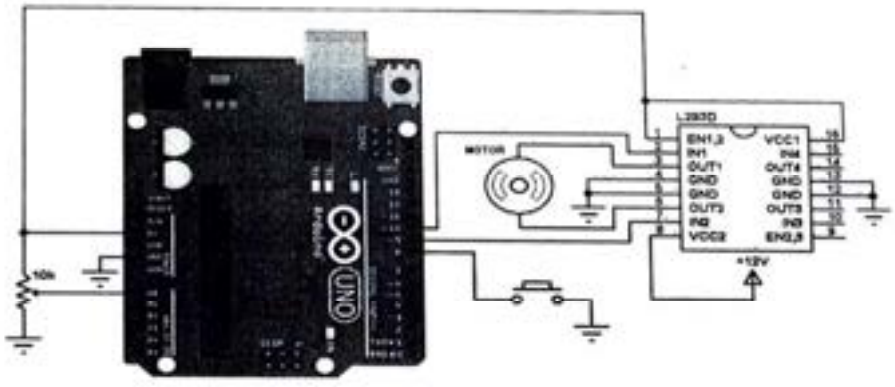

Figure 4.11 Arduino DC Motor control

Using L293D/L298

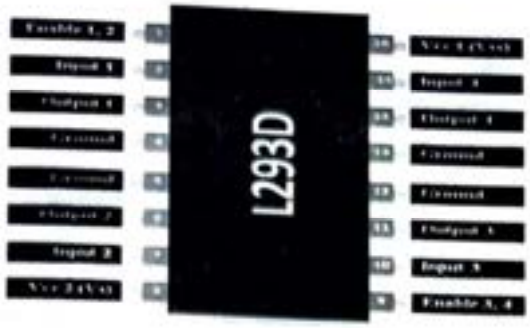

Figure 4.12L293D pin configuration

4.2.8 Power supply

Power supply unit (or PSU) converts mains AC to low-voltage regulated DC power for the internal components of a computer. Modern personal computers universally use switched-mode power supplies. Some power supplies have a manual switch for selecting input voltage, while others automatically adapt to the mains voltage

Rechargeable battery, storage battery, secondary cell or accumulator is a type of electrical battery which can be char Rechargeable battery, storage battery, secondary cell or accumulator is a type of electrical battery which can be charged, discharged into load and recharged many times.

Block diagram

The ac voltage, typically 220V rms, is connected to a transformer, which steps that ac voltage down to the level of the desired dc output. A diode rectifier then provides a full-wave rectified voltage that is initially filtered by a simple capacitor filter to produce a dc voltage. This resulting dc voltage usually has some ripple or ac voltage variation. A regulator circuit removes the ripples and also remains the same dc value even if the input dc voltage varies, or the load connected to the output dc voltage changes. This voltage regulation is usually obtained using one of the popular voltage regulator IC units.

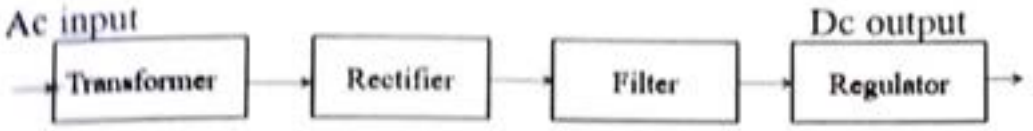

Figure4.13 Block diagram (Power supply)

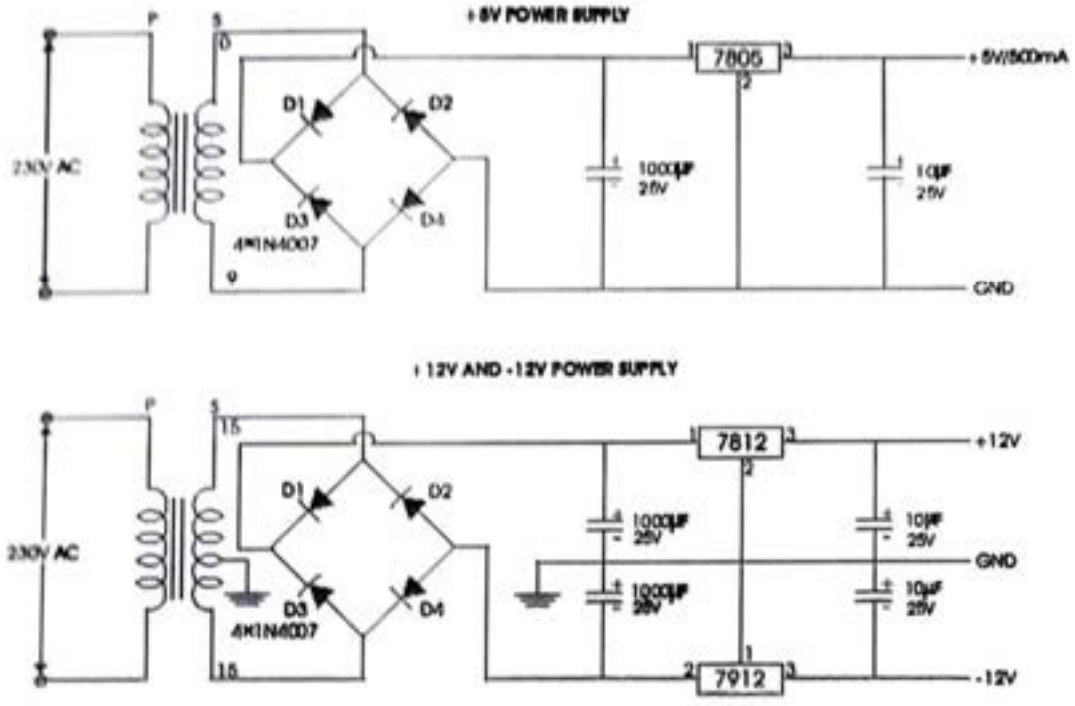

Figure 4.14 Circuit diagram (Power supply)

4.1.9 Regulator

A voltage regulator is used to produce a constant linear output voltage. It's generally used with AC to DC power supply. And also it can be used as well as a DC to DC voltage convertor.

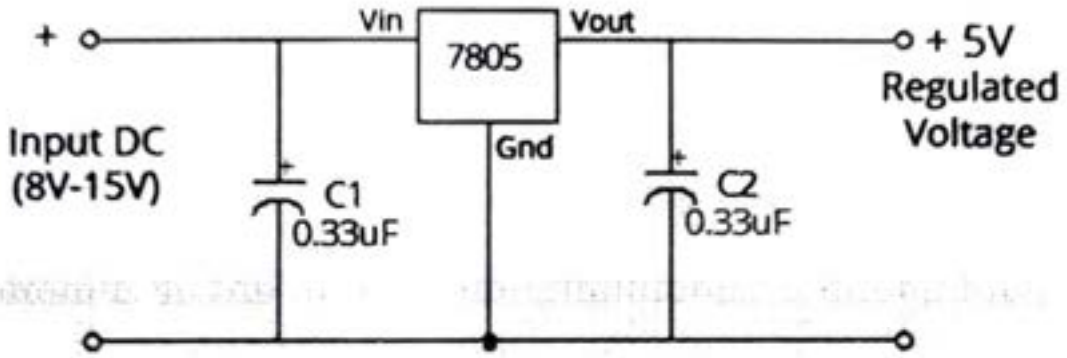

Figure4.16 voltage regulator circuit

To regulating low voltage, most used device is one single IC. 7805, 7812, 7905 etc. 78xx series are design for positive and 79xx series are for Negative voltage regulator. 7805 is a three terminal +5v voltage regulator IC from 78XX chips family. See 7805 pin out below. LM78XX series are from National Semiconductor. They are linear positive voltage regulator IC; used to produce a fixed linear stable output voltage.

4.1.10 Rectifier

Rectifier is converted into Ac into pulsating DC. A rectifier is an electrical device that converts alternating current (AC), which periodically reverses direction, to direct current (DC), which flows in only one direction.

Before the development of silicon semiconductor rectifiers, vacuum tube thermionic diodes and copper oxide or selenium-based metal rectifier stacks were used. With the introduction of semiconductor electronics, vacuum tube rectifiers became obsolete, except for some enthusiasts of vacuum tube audio equipment. For power rectification from very low to very high current, semiconductor diodes of various types (junction diodes, Schottky diodes, etc.) are widely used. Other devices that have control electrodes as well as acting as unidirectional current valves are used where more than simple rectification is required e.g., where variable output voltage is needed. High-power rectifiers, such as those used in high-voltage direct current power transmission, employ silicon semiconductor devices of various types. These are thyristors or other controlled switching solid-state switches, which effectively function as diodes to pass current in only one direction.

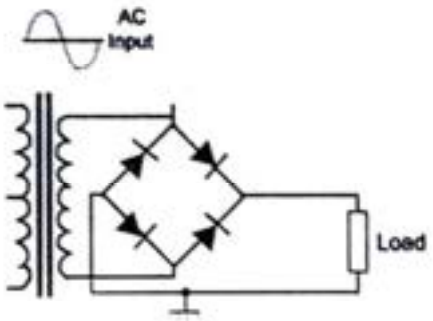

Figure4.17 Rectifier

4.1.11 Buzzer

Buzzer is the convenient sound generator utilized as a part of electronic circuits to give sound sign. It is broadly utilized as caution generator in electronic gadgets. It is accessible in different sorts and size to suit the prerequisites. A Piezo bell has a Piezo circle and an oscillator inside. At the point when the ringer is controlled, the oscillator

creates a recurrence around 2-4 kHz and the Piezo component vibrates as needs be to deliver the sound. A conventional Piezo bell works between 3 – 12 volts DC.

Features

- The PS series are high performance buzzers that employ uni-morph piezoelectric elements and are designed for easy incorporation into various circuits.
- They feature extremely low power consumption in comparison to electromagnetic units.
- Because these buzzers are designed for external excitation, the same part can serve as both a musical tone oscillator and a buzzer.
- They can be used with automated inserters, moistureresistant models are also available.

Figure 4.18 Buzzer

4.1.12 VIBRATION SENSOR

A piezoelectric sensor is a device that uses the piezoelectric effect to measure pressure, acceleration, strain or force by converting them to an electrical signal.

Vibration sensor is used originally as vibration switch because of its high sensitivity; it is sensitive to environment vibration, and generally used to detect the ambient vibration strength.

Figure 4.19 vibration sensor

Table 4.5 Vibration sensor features

Model name	SW -18010P
Type	Vibration sensor switch
Material	Metal ,PVC
Supply voltage	3.3V to 5V
Current	< 50 mA
PCB board size	3.2 cm× 1.4 cm
Closed resistance	< 30 ohm
open resistance	> 10M ohm
Output form	Digital switch output(0&1)
Temperature range	Storage:-40˚C-85˚CC, Operating:-25˚CC to 85˚C
Conductive time	2ms
Humidity	95%RH,40˚C for 96 hours

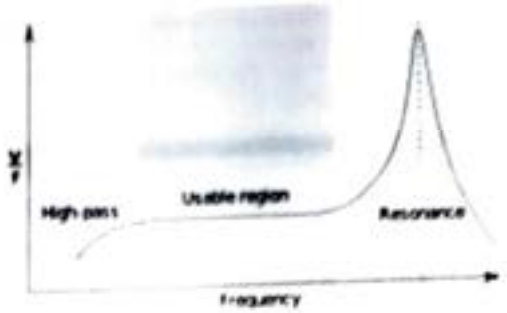

Figure 4.20 Frequency response of a piezoelectric sensor: Output voltage vsapplied force.

Sensing materials

Two main groups of materials are used for piezoelectric sensors: piezoelectric ceramics and single crystal materials. The ceramic materials (such as PZT ceramic) have a piezoelectric constant / sensitivity that is roughly two orders of magnitude higher than those of single crystal materials and can be produced by inexpensive sintering processes. The less sensitive crystal materials (gallium phosphate, quartz, and tourmaline) have a much higher – when carefully handled, almost infinite – long term stability.

4.1.13 MOBILE CALL DETECTOR

A digital telecommunication, pulse shaping is the process of changing the waveform of transmitted pulses. Its purpose is to make the transmitted signal better suited to the communication channel by limiting the effective bandwidth of the transmission. By filtering the transmitted pulses this way, the intersymbol interference caused by the channel can be kept in control. In optics, femtosecond pulse shaping is a technique that modifies the temporal profile of an ultra-short pulse from a laser. Pulse shaping can be used to shorten/elongate the duration of optical pulse, or to generate more complex pulses.

Use of Cell Phone Detector

It is also useful for detecting the use of mobile phone for spying and un-authorized video transmission. Certain places where use of mobile phones are not allowed like exam hall, temple, offices and theaters. in those places to detect and restrict the use of mobile phones this proposed system is very helpful. This must detect the incoming and outgoing calls, SMS and video transmission even if the mobile phone is kept in the silent mode. The illegal use of cell phones is a growing and dangerous problem in correctional institutions worldwide. These devices are a significant threat to prison security and circumvent the monitoring processes in prisons, while helping inmates commit new crimes both inside and outside the facility.

TABLE 4.6 Mobile Call Detector Features

Technology Used	RF Technology
Frequency range	0.9 to 3 GHz
Wavelength	3.3 to 10 cm
Transmitter power	20 -100 watts
Transistors output	10mV
Bandwidth Resolution	2MHz
Bandwidth	824 - 894 MHz band
Sensitivity	-60 dBm
Coverage	40 to 50 foot radius

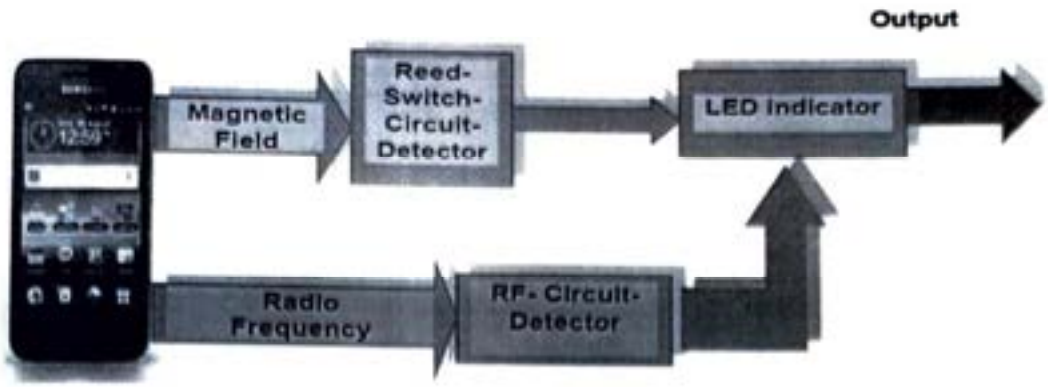

Figure 4.21 Block Diagram for RF Technology

4.1.14 WATER VALVE

A Water valve is an electro mechanical valve for use with liquid or gas controlled by running or stopping an electrical current through a solenoid, which is a coil of wire, thus changing the state of the valve. The operation of a solenoid valve is similar to that of a light switch, but typically controls the flow of air or water, whereas a light switch typically controls the flow of electricity. Solenoid valves may have two or more ports: in the case of a two-port valve the flow is switched on or off; in the case of a three-port valve, the outflow is switched between the two outlet ports. Multiple solenoid valves can be placed together on a manifold.

Solenoid valves are the most frequently used control elements in fluidics. Their tasks are to shut off, release, dose, distribute or mix fluids. They are found in many application areas. Solenoids offer fast and safe switching, high reliability, long service life, good medium compatibility of the materials used, low control power and compact design.

Solenoid valves may use metal seals or rubber seals, and may also have electrical interfaces to allow for easy control. A spring may be used to hold the valve opened or closed while the valve is not activated.

- Arduino IDE

CHAPTER 5

RESULT AND DISCUSSIONS

In this project we have developed a real time model in embedded system. By fitting the alcohol sensor in the steering of the four wheeler that can automatically lock the engine when a drunken driver tries to drive a car. With the help of GPS and GSM, we can track the location and send the message to the user. We can save the life of driver and also the passengers. The proposed method is verified to be a highly beneficial for the automotive industry. The kit shown in figure.5.1

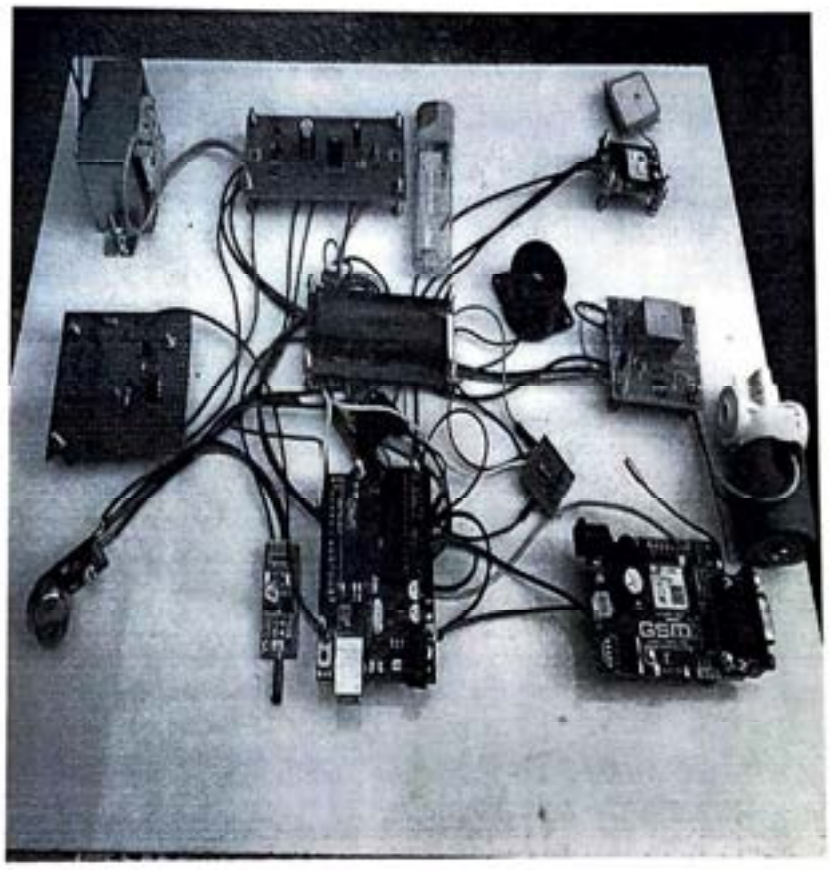

Figure 5.1 Hardware Kit

CHAPTER 6

WORK TO BE DONE IN PHASE II

CONCLUSION

By implementing this system in vehicle, a safe journey is possible which would reduce the accident rate due to drunken driving. This system has the accident prevention technology which would sense the alcohol breath. If there any trace of alcohol set limit, then the system will stop the engine and track the location with sent the message to the pre-defined number. Additional features such as mobile call detector and vibration sensor are also included. Whenever accident occurs, Vibration sensor is used for the indication of accident to the user and Mobile call detector is used to detect the incoming and outgoing calls, and SMS etc.,

ABSTRACT

Several parameters contribute to the growth of plants in a commercial greenhouse, namely soil moisture, soil temperature, atmospheric temperature and humidity, carbon dioxide (CO_2) and light intensity. Maintaining optimal levels of these environmental parameters is essential for healthy growth of the plants and to maximise yields in terms of fruits and flowers. Monitoring only a few parameters, such as temperature and humidity, while neglecting others, leads to inaccurate observations and sub-optimal yields. At the same time, increases in greenhouse sizes have forced the growers to increase measurement points (sensor stations) to accurately track changes in the environment. However, increases in measurement points mean increases in installation and maintenance cost of the sensor stations. In this paper, an automated wireless greenhouse climate monitoring system has been detailed with special emphasis on the programming aspects and testing of a temperature and humidity sensor. The proposed system consists of three units- Sensor Station (SS), Coordinator Station (CS) and Central Control Station (CCS). The backbone of the wireless network is based on ZigBee modules for communication between the SS and CS whereas the communication between the CS and CCS uses a XStream proprietary RF modem. Field trials conducted have established the functionality and reliability of the designed wireless sensor network. The overall system architecture shows advantages in cost, size, power, flexibility and distributed sensing.

CHAPTER 1

INTRODUCTION

1.1 Introduction

We live in the world where everything can be controlled and operated automatically, but there are still a few important sectors in our country where automation has not been adopted or not been put to a full-fledged use, perhaps because of several reasons one such reason is cost. One such field is agriculture. Agriculture has been one of the primary occupations of man since early civilizations and even today manual interventions in farming are inevitable .Greenhouses form an important part of the agriculture and horticulture sectors in our country as they can be used to grow plants under controlled climate conditions for optimum produce. Automating a greenhouse envisages monitoring and controlling of the climatic parameters which directly or indirectly govern the plant growth and hence their produce. Automation is process control of industrial machinery and processes, thereby replacing human operations.

We live in a world where each and everything can be controlled and operated automatically, but still there are still a few important sectors in our country where even now automation has not been adopted some cases has not been put to a full-fledged use, perhaps because of certain reasons. Among all one such reason is cost. And the one such field is agriculture. Agriculture is one of the primary occupations of man since early civilizations. Manual interventions in farming even today are inevitable. The greenhouse industry is one of the fastest growing sectors across the globe. The work of the greenhouse is to separate the crop from the environment and to provide shelter from the direct influence of the weather conditions prevailing externally. This in turn enables the production of crops which otherwise can't be produced at that specific location. Greenhouses are those that form an important part of the agriculture and horticulture sectors in our country as they can be used to grow plants under controlled climatic conditions for optimum production. The greenhouse environment enables the manipulation of the crop environment. This asset allows the farmer in several ways mainly is to improve the cultivation in a way that the plants need. This leads certain advantages like higher crop yield, prolonged production period, better quality, and lesser use of protective chemicals.

The added value per unit area in greenhouse crops is very much higher than that is prevailing in the open-field cultivation. In moderate climatic zones, some energy is needed, whereas in arid zones, the cooling and availability of water is a major concern. The usage of materials, energy, crop yield and quality can be influenced by operation of greenhouse by adjusting its components, such as heating and cooling inputs, window opening, drip irrigation, screening and CO2 dosage. Thus, hopefully we can expect that, by the way these controls are operated; it influences the final economic result. In order to fully exploit the enhanced possibilities for crop and resource management in the greenhouse, it is indispensable to know the control variables with a remote sensing system installed to it. Finally, automation in a greenhouse helps in monitoring and controlling of the climatic parameters which directly or sometimes indirectly governs the plant growth hence that results in a profitable production. Greenhouses in India are being employees in the high-altitude regions where the sub- zero temperature up to -40° C makes any kind of plantation which is almost impossible and in arid regions where in the conditions for plant growth are hostile. In the present people are moving around the world, hence there is an increased demand for connectivity with our properties wherever in we are on the planet. So here comes the role of connecting every device to the internet so that it is accessible wherever we have an internet access across the globe. This interesting fact has thrown upon us the need for the implementation like a solution of integrating our present resources. This is how internet of things comes into the picture. This project extensively focuses on implementation of a smart greenhouse that can monitor using IOT technology.

The increase in living standards and higher consumer demands have increased pollution of the air with CO2 and other greenhouse gases; particulate matter of water along with a variety of chemicals, nutrients, and oil spills; and of the soil owing to the disposal of hazardous wastes, application of herbicides and pesticides, and disposal of non-biodegradable materials, etc. Man-made chemicals like pesticides, cosmetics, personal and household care products, and pharmaceuticals, which are in use worldwide and are indispensable for modern society, are adding pollutants to the atmosphere . Furthermore, human activities have resulted in contamination of water resources with biological micropollutants, such as viruses and bacteria. Such agents have generated renewed awareness due to their potential pathogenicity and are referred to as emerging or reemerging pathogens. Biological micropollutants, such as enteric

bacteria, mycoplasmas, viruses, and protozoa, are the source of many waterborne diseases and remain a major cause of death worldwide . For the overall safety and security of living systems, there should be a comprehensive analysis of toxicants, as well as their detection and continuous monitoring in environmental samples of soil, water, and air. Two different approaches have been considered for monitoring pollutants in environmental samples. The traditional approach provides accurate analysis of chemical or physical properties of environmental samples but requires costly analytical instruments with specialized laboratories for analysis of pollutants present in the samples.

However, these systems of analysis fail to provide information on the bioavailability of pollutants and related effects on biological systems. To overcome shortcomings of the traditional approach, a complementary approach is being evaluated where living systems are used for environmental sample bioassays. Unicellular microorganisms, particularly bacterial systems, are used for such purposes. It is because of their rapid growth rate, large population size, and minimum requirement for growth and maintenance (low cost). The Korean Society for Microbiology and Biotechnology Environmental security is one of the major concerns for the safety of living organisms from a number of harmful pollutants in the atmosphere. Different initiatives, legislative actions, as well as scientific and social concerns have been discussed and adopted to control and regulate the threats of environmental pollution, but it still remains a worldwide challenge. Therefore, there is a need for developing certain sensitive, rapid, and selective techniques that can detect and screen the pollutants for effective bioremediation processes. In this perspective, isolated enzymes or biological systems producing enzymes, as whole cells or in immobilized state, can be used as a source for detection, quantification, and degradation or transformation of pollutants to non-polluting compounds to restore the ecological balance. Biosensors are ideal for the detection and measurement of environmental pollution in a reliable, specific, and sensitive way. In this review, the current status of different types of microbial biosensors and mechanisms of detection of various environmental toxicants are discussed systems can be genetically engineered to analyze the pollutants in their environmental conditions. Furthermore, proteins that are present in cells can also be applied for the detection of a specific analyse.

CHAPTER 2

LITERATURE SURVEY

2.1. Iot Based Intelligent Greenhouse Monitoring and Control System

International Journal,value 7 Issue No.2.May 2014.

2.1.1 Introduction

IoT Technology has been used to reduce the distance between the staff in the article "Things" and its digital impersonation in data frameworks. It's seen as the next generation network (NGN) of the internet . The IoT is driven by an extension of the Internet through the incorporation of physical articles joined with a capacity to provide more quick-witted administrations to the earth as more information ends up noticeably accessible. Several application areas going from Green-IT and vitality effectiveness to coordination's are now beginning to profit by Internet of Things ideas . A Greenhouse provides basic methods for employment to its proprietor and must be financially pragmatic for the specific atmosphere in which it stands. Also, Greenhouse could be defined as advanced Innovation for Protected Horticulture addresses the major natural elements of light, temperature, and irrigation . This paper investigates the usefulness of using the IoT based on the greenhouse to utilize low-cost tools and decrease the effort of the Pleasants. This could be implemented by including the automation in irrigation process, conserving temperature, and the degree of brightness inside the greenhouse structure. More recent attention has been focused on the provision of improvement on the Internet of things (IoT) and how to utilize it with the various applications. The IoT is interesting subject that recently whiteness very large number of papers that aimed to develop this technology.

2.1.2 Proposed Technique

2.1.2.1 IoT Structure

The function of IoT in this work gives the pleasant the ability to monitor and control their greenhouses remotely. To make the work of IoT easy to understand, provide an imagination about how the IoT work in upload and download data and deliver it to the control systems.

2.1.2.2 Design a web application

The First step was designing a web page to display the information for the user. The web page should be easy to use, attractive, and has a simple HTML code in order to speed up the execution of functions of the web page. The designed web application is important to be secured with Username and password for each user. Also, the permissions of each member are different, a part of members are authorized to access, monitor, and control the systems.

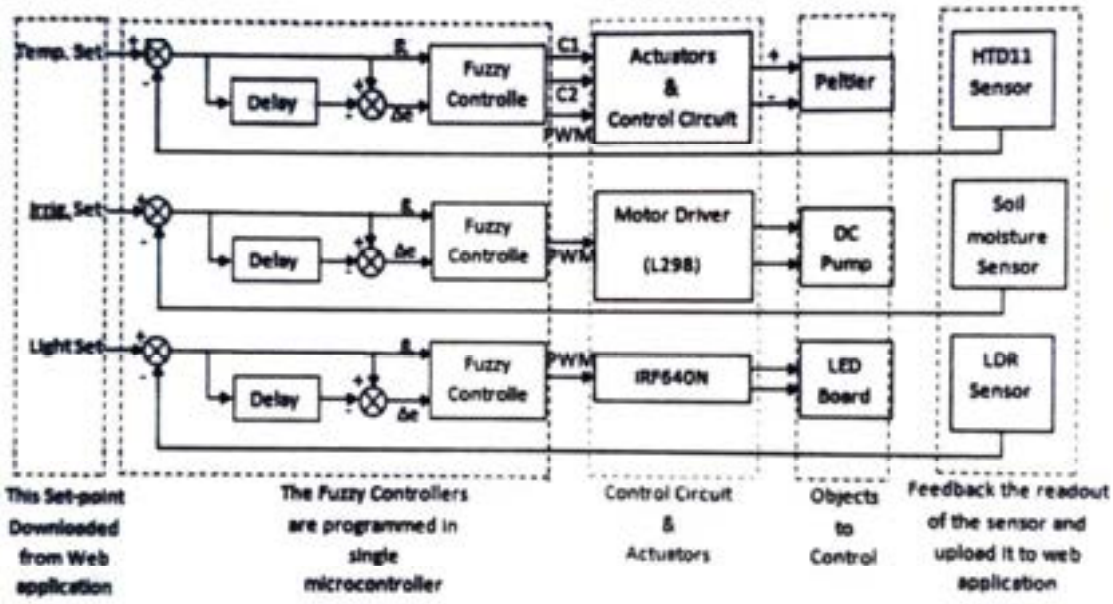

Figure 2.1 Block diagram of the greenhouse system

Table 1.1 The IOT time calculation

No.	Time of Action	Time to Downloading Set-points	Time To Uploading the System Status
1	10:32 PM	220 msec.	1178 msec.
2	12:06 AM	357 msec.	1572 msec.
3	08:31 PM	188 msec.	1152 msec.

Figure 2.2 The web application control and monitor

2.1.2.3 Local communications of nodes

In order to make several nodes capable to connect to internet and download the set-points and upload their system status, the master-slave technique could be used. The master would be defined as node that has the ability to connect to the public internet by the Ethernet to download/upload the nodes data. Also, the master node communicate locally with others node by using the RF Transmitter. While, the slave node is only communicate with slave node to send their status and receive the set-point that specified for its control system.

2.1.2.4 Remotely Management and Monitor the system's status:

In this article, attempt to construct a prototype IoT, using simple, cheap, and available tools. To apply the IoT in a practical application, there are many tools should be employed like Ethernet Arduino Shield and Arduino microcontroller. The Ethernet plays as the main tool which makes a connection between the greenhouse and the router that acts as a gateway.

2.1.3 Conclusion

The intelligent greenhouse, the resulting prototype has numerous advantages like employing three intelligent control systems (Cooling/Heating System, Irrigation Control System, Light Control System). These control systems are managed by Fuzzy controllers which designed and programmed inside the microcontroller (standalone) without requiring any external

processing, this provides the ability to describe the system as practical system. Also, the IoT provide features that may make the works of the peasant much easier by enable them to monitor their plants and make a suitable decision by adjusting the set-points to accommodate any changes may effect on growing the plants.

2.1.4 Result

The operation of the cooling/heating system, the irrigation system, and the lighting system depending on the set-points. Finally, upload the readout of the sensor to the web application. In order to calculate the system sampling time, each system should be determined individually. The temperature control system, irrigation control system, and light intensity control system are take 308, 259, and 115 milli sec respectively.

2.1.5 Draw Back

The IoT depend on the public internet to deliver its data, so that it could be effected directly by the internet problems such congestion. Also, the LDR has been used as light intensity sensor. This tool may produce unprecise result and that may effect on the overall system performance such as the overshot that appear.

2.2 Remote Control System for Greenhouse Environment using Mobile Devices

International Journal Research & Technology ISSN:2278-0181.

2.2.1 Introduction

Production of competitive crop and greater income, farmers need efficient cultivation and management techniques. Remote control of the environment for protected production facilities using wireless sensing and control technologies may increase crop yield and quality, and also reduce labor requirement. A greenhouse control system consisted of 4 sub-levels: 1st level to manage and operate sensors and equipment, 2nd level to integrate the 1st level units, 3rd level for communication, and 4th level to operate the entire system by users. A modular measuring equipment using Micro Controller Unit (MCU) for cultivated land. It used eight-channel multiplexing card to measured temperature and humidity, and solar radiation and rainfall sensors were connected directly to the MCU, and then transferred to a server computer through RS-232 communication port. The amount of used water in sensor-based and timer-based irrigation systems, and reported that 11% of the water could be saved in the sensor-based system. A sensor network using MCU, Zigbee protocol to measure temperature and humidity for greenhouse, and applied the sensor network for heater operation.

2.2.2 Proposed Technique

WCN part installed at multiple locations in a greenhouse, user part to monitor the environment and send control commands, and central management part to receive and process commands, and connect WCN and users. Each WCN node included MCU-based relay node and Zigbee communication module. User part utilizes mobile devices to send control commands using CDMA, 3G, or Wi-Fi communication. Central management program was coded in Visual Basic ver. 6.0 to process control commands and activate the WCN relay nodes.

Wireless communication, a Zigbee-base module was used. The communication module featured low power consumption, micro sized and low cost module. It could transfer data in a 250-kbps speed among up to 65,000 nodels within 10~20 with the IEEE802.15.4 communication protocol.

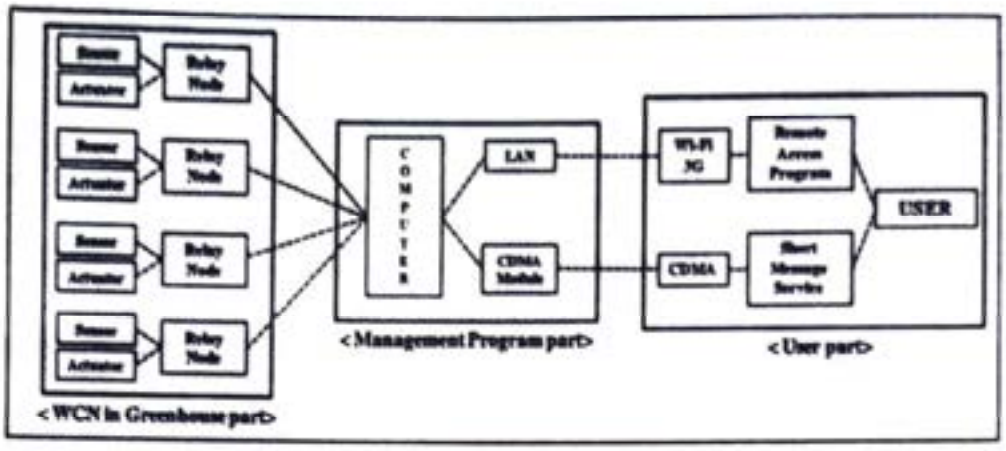

Figure 2.3 Concept of remote control system using WCN and mobile device

Performance of the remote control system was evaluated in terms of communication success ratio, response time, power consumption. Time required to activate relay node was measured by number of node. Response time to control environment was also measured. Irrigated water was monitored for 15 minutes on 1-minute intervals. Response time of the window motor was evaluated for different partial opening and closing levels. For heating and ventilation, temperature and humidity sensors were installed at 1-m distance from the heater and fan. Illumination intensity was measured under the light source. For each WCN component, power consumption was also evaluated.

2.2.3 Result

Temperature values were both 16°C and humidity values were 60 and 66%, respectively. With heater operation, inside temperature increased logarithmically and was maintained at 24±0.5°C after 2 hours. Air relative humidity was decreased to 50% after 20 minutes, and maintained at 43±0.5% after 2 hours.

Irrigation and window operation showed linear patterns, irrigated rate was 2.76 mL/min, and required time to control window opening by 10% of the full range was about 11.14 s.

Communication and remote control was successful for all cases. Depending on location, response times were less than 14 seconds for Wi-Fi communication conditions. For 3G

communication, response times were 10.55 and 15.71 seconds for stationary (0 km/h) and high speed (100 km/h) conditions, respectively. They were less than 12.35 seconds for sending remote control command using CDMA SMS service.

2.2.4 Conclusion

Performance of remote access under Wi-Fi condition High Signal Intensity Low Signal Intensity Home Office Hotspot Home Office Hotspot No. of success 30 30 30 30 30 30 Response time (s) 4.82 7.26 12.86 14.22 14.29 14.82 .

Performance of remote access under 3G condition 0 km/h 100 km/h No. of success 30 30 Response time (s) 10.55 15.71 .

Performance of remote access under CDMA condition -95 ~ -80 (dBm) -79 ~ -60 (dBm) No. of success 30 30 Response time (s) 12.35 9.84 .

Generally, actual power consumption levels were lower than the rated levels. For solenoid value, power level was about 2.11 W, which was greater than the rated level, but decreased and stably maintained at about 1.61 W. Initial operation of the irrigation pump required about 193.25 W, and the level increased up to 236.97 W with full amount of water flow, but they were lower than the rated power consumption level. The heater-cooler consumed the greatest power with average of 1753.43 W and the maximum of 2957 W at the initial operation period. Ventilation fan and lighting bulb required about 26.23 W and 18.93 W, respectively. Window more required 54.86 W, while a relay node required about 0.41 W. Estimation of power consumption during crop production should consider duration and interval of operation.

2.2.5 Draw Back

Due to the use of Wi-Fi for the remote control it can cover very minimum distance. so that the Wi-Fi technique is not possible for large area of greenhouse.

2.3 ARDUINO Based Automatic Plant Watering System

International Journal Of Computer Science And Mobile Computing, Vol.5 Issue.8, Auguest-2016.

2.3.1 Introduction

Irrigation is the artificial application of water to the land or soil. It is used to assist in the growing of agricultural crops, maintenance of landscapes, and re vegetation of disturbed soils in dry areas and during periods of inadequate rainfall. When a zone comes on, the water flows through the lateral lines and ultimately ends up at the irrigation emitter (drip) or sprinkler heads. Many sprinklers have pipe thread inlets on the bottom of them which allows a fitting and the pipe to be attached to them. The sprinklers are usually installed with the top of the head flush with the ground surface. When the water is pressurized, the head will pop up out of the ground and water the desired area until the valve closes and shuts off that zone. Once there is no more water pressure in the lateral line, the sprinkler head will retract back into the ground. Emitters are generally laid on the soil surface or buried a few inches to reduce evaporation losses. Healthy plants can transpire a lot of water, resulting in an increase in the humidity of the greenhouse air. A high relative humidity (above 80-85%) should be avoided because it can increase the incidence of disease and reduce plant transpiration. Sufficient venting or successive heating and venting can prevent condensation on plants surfaces and the greenhouse structure. The use of cooling systems during the warmer summer months increases the greenhouse air humidity. During periods with warm and humid outdoor conditions, humidity control inside the greenhouse can be a challenge. Greenhouses located in dry, dessert environments benefit greatly from evaporative cooling systems because large amounts of water can be evaporated into the incoming air, resulting in significant temperature drops. Since the relative humidity alone does not tell us anything about the absolute water holding capacity of air, a different measurement is sometime used to describe the absolute moisture status of the soil.

The vapor pressure deficit is a measure of the difference between the amount of moisture the air contains at a given moment and the amount of moisture it can hold at that temperature when the air would be saturated. Pressure deficit measurement can tell us how easy it is for

plants to transpire: higher values stimulate transpiration (but too high can cause wilting), and lower values inhibit transpiration and can lead to condensation on leaf and greenhouse surfaces. In the mid 20th century, the advent of diesel and electric motors led to systems that could pump groundwater out of major aquifers faster than drainage basins could refill them. This can lead to permanent loss of aquifer capacity, decreased water quality, ground subsidence, and other problems. Apart from all these problems and failures, there has been a considerable evolution in the methods to perform irrigation with the help of technology. The application of technology in the areas of irrigation has proven to be of great help as they deliver efficiency and accuracy.

2.3.2 Proposed Technique

The ATmega328 on the Arduino Uno comes preburned with a boot loader that allows you to upload new code to it without the use of an external hardware programmer. It communicates using the original STK500 protocol (reference, C header files).We can also bypass the boot loader and programs the microcontroller through the ICSP (In-Circuit Serial Programming) header; see these instructions for details.

Figure 2.4 Automatic plant watering block diagram

The ATmega16U2 (or 8U2 in the rev1 and rev2 boards) firmware source code is available. The ATmega16U2/8U2 is loaded with a DFU boot loader, which can be activated by: On Rev1 boards: connecting the solder jumper on the back of the board (near the map of Italy) and then resetting the 8U2. On Rev2 or later boards: there is a resistor that pulling the 8U2/16U2 HWB line to ground, making it easier to put into DFU mode.

The Arduino Uno has a number of facilities for communicating with a computer, another Arduino, or other microcontrollers. The ATmega328 provides UART TTL (5V) serial communication, which is available on digital pins 0 (RX) and 1 (TX). An ATmega16U2 on the board channels this serial communication over USB and appears as a virtual com port to software on the computer. The '16U2 firmware uses the standard USB COM drivers, and no external driver is needed. However, on Windows, a .inf file is required. The Arduino software includes a serial monitor which allows simple textual data to be sent to and from the Arduino board. The RX and TX LEDs on the board will flash when data is being transmitted via the USB-to-serial chip and USB connection to the computer (but not for serial communication on pins 0 and 1). A Software Serial library allows for serial communication on any of the Uno's digital pins. The ATmega328 also supports I2C (TWI) and SPI communication. The Arduino software includes a Wire library to simplify use of the I2C bus.

Table 2.1 Arduino specifications

FEATURE	SPECIFICATION
Microcontroller	ATmega328
Operating Voltage	5V
Input Voltage (recommended)	7-12V
Input Voltage (limits)	6-20V
Digital I/O Pins	14 (of which 6 provide PWM output)
Analog Input Pins	6
DC Current per I/O Pin	40 mA
DC Current for 3.3V Pin	50 mA
Flash Memory	32 KB (ATmega328) of which 0.5 KB used by boot loader
SRAM	2 KB (ATmega328)
EEPROM	1 KB (ATmega328)
Clock Speed	16 MHz

2.3.3 Result

The water pump is used to artificially supply water for a particular task. It can be electronically controlled by interfacing it to a microcontroller. It can be triggered ON/OFF by

sending signals as required. The process of artificially supplying water is known as pumping. There are many varieties of water pumps used. This project employs the use of a small water pump which is connected to a H-Bridge.

2.3.4 Conclusion

It has been developed by integrated features of all the hardware components used. Presence of every module has been reasoned out and placed carefully, thus contributing to the best working of the unit. Thus, the Arduino Based Automatic Plant Watering System has been designed and tested successfully. The system has been tested to function automatically. The moisture sensors measure the moisture level (water content) of the different plants. If the moisture level is found to be below the desired level , the moisture sensor sends the signal to the Arduino board which triggers the Water Pump to turn ON and supply the water to respective plant using the Rotating Platform/Sprinkler. When the desired moisture level is reached , the system halts on its own and the Water Pump is turned OFF.

2.3.5 Draw Back

Expensive technique. It requires probe to be inserted in the soil it requires labor to collect the data and maintain the measurement processes. The watermark sensors provide less accuracy in sandy soils due to large particles

2.4 Greenhouse Monitoring and Automation using GSM Module

Journal Of Information, Knowledge And Research In Electronics And Communication Engineering ,September-2000.

2.4.1 Introduction

The concern with a lot of consumer needs and demand for the agriculture products has stimulated awareness among the farmer that increases their products in the market by implementing advance technologies in this industry. The products that are important that may come to the farmers' interest that controls the use of natural sources and natural environment which controls agriculture with various aspects. Therefore, this problem makes farmers interest to implement agro-conditions sending alert notification messages to farmers using GSM and SMS technology. The proposed system is aimed to be a reliable and cost environment with remote monitoring method in their agriculture field.

For some crucial plants such as vegetarian and flowers plants, which need 24 hours attention from human so that the plant quantities and qualities are controlled with proper management by the collected data and information from the fields. This will provide enormous foundation for future growth and future development of their plants in the green house. However, with the increasing size in farming areas, this type of manual practice is increases time consuming and cost of the labour. However, with the growth of management in agriculture techniques and with modern telecommunication technologies which provides great assistance with the implementation in the agriculture industry. With the rapid development in telecommunication and wireless technologies, it is proved that wireless communication has good practice for remote sensing in the agriculture industries. In this paper uses wireless sensor network, Global System for Mobile Communication (GSM) and short message service (SMS) to carry out data from the green house with sensors directly alert the farmers to their mobile phone. This type of practice can eliminate the use in the farming areas. This technology has seen to be suitable for these modern days. Moreover, this paper focuses on the monitoring and automation system in greenhouse which has capability of controlling.

2.4.2 Proposed Technique

2.4.2.1 GSM Module

A GSM modem is a wireless modem that works with a GSM wireless network. A wireless modem behaves like a dial-up modem. The main difference between them is that a dial-up modem sends and receives data through a fixed telephone line while a wireless modem sends and receives data through radio waves. Like a GSM mobile phone, a GSM modem requires a SIM card from a wireless carrier in order to operate.

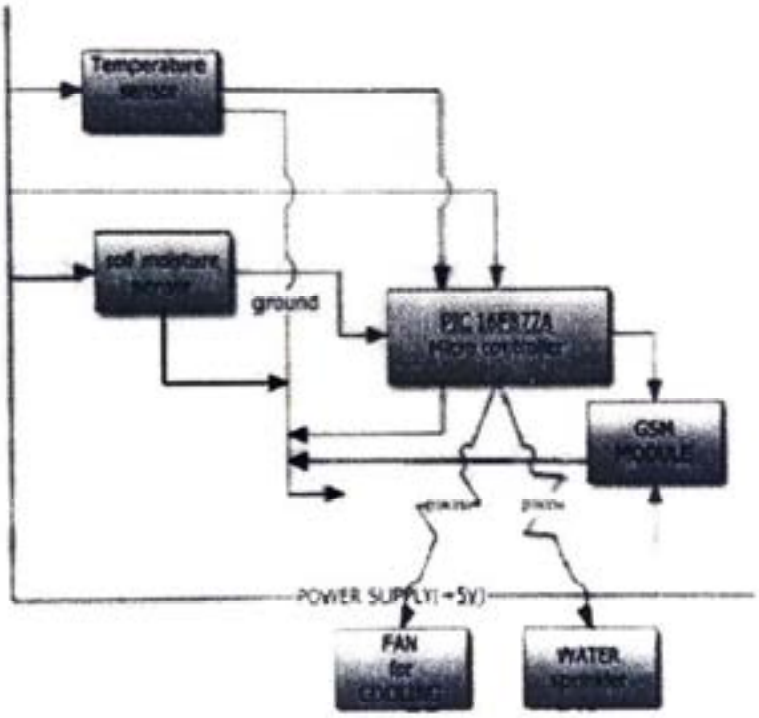

Figure 2.5 Block diagram of the system

2.4.3 Result

The system consist of two subsystems temperature monitor and soil moisture and control system. The system operates according to the flow chart show. The temperature monitor and control system consist of a LM35 temperature sensor a user mode switch the fan for cooling. The user mode switch is connected to RB7 pin in the microcontroller and tested whether the switch

is ON, if it is ON (RB7read as high) the microcontroller saves the value to the EEPROM set by the user by means of the potentiometer connected to the RA1 pin. The analogue input value is converted to a digital value inside the microcontroller and the value is saved in the variable. Then it will be written to an address location of the EEPROM which in this case is 0x10. The program then checks again whether the user mode switch is pressed and if it is ON once again the program convert the analogue input value to digital and saves it in the value set by the user. In this mode the temperature sensor detects the current temperature value and inputs it to RA0 pin of the microcontroller. The input is an analogue input and it is converted to a digital input and calibrated as follows. The resulting value after A/D conversion is reduced by a constant 1 and divided by 2. Then it is displayed and checked with the user defined temperature value saved in the EEPROM. If the result is negative it means that the current temperature value is greater than the user defined temperature value so the microcontroller makes the RB7 pin high to ON the cooler fan to bring down the temperature to the user defined value and sends SMS alerts to the user. If both the values are equal the result is zero then both RB7 pin is set to low hence fan is switched off and sends SMS alert to user mobile.

2.4.4 Conclusion

With the wide improvement of wireless and GSM technology. The system may be cost with wireless sensors may little cost but it works with more effectively. The system may be implemented with the help of many technologies but these technologies more reliable, easy to implement, works effectively and easy to operate.

2.4.5 Draw Back

This paper uses a GSM module technology. This can be improved by the new technology of wireless communication. Because the GSM module cover short distance.

2.5 Greenhouse Monitoring and Conclusion using ARM

Basrah Journal For Engineering Sciences, Vol. 17, No. 1, 2017.

2.5.1 Introduction

The greenhouse industry is the fastest growing sector worldwide. The greenhouse separates the crop from the environment, This enables the production of crops that otherwise could not be produced at that specific location. The greenhouse enclosure permits the manipulation of the crop environment. This asset allows the farmer to steer the cultivation in a desirable direction. It leads to higher crop yield, prolonged production period, better quality, and less use of protective chemicals. The crop yield and quality can be influenced by operating the adjustable components of greenhouse. To fully exploit the enhanced possibilities For crop and resource management in greenhouse, it is indispensable to adjust and control variables with a remote controlling system via SMS by using the GSM - SMS. This is because it is almost difficult for human being to manipulate and be present every day near the system.

2.5.2 Proposed Technique

2.5.2.1 GSM Modem

A GSM modem is a specialized type of modem, which accepts a SIM card, and operates over a subscription to a mobile operator, just like a mobile phone. From the mobile operator perspective, a GSM modem looks just like a mobile phone. A GSM modem can be a dedicated modem device with a serial, or it may be a mobile phone that provides GSM modem capabilities. Here SIM 300 Modem is used.

2.5.2.2 Hardware Implementation and Description

Various Parameters are taken such as Temperature, Humidity, Light will sense gives a voltage output corresponding to values. This signal is taken into LPC2148 processor through the analog input channel for comparison. This signal is digitized using the inbuilt 10-bit ADC of the LPC2148 processor and compare the data with Predefined data for any status changes or value crossing the limit. Then System will send the message to concerned authority(s) by sending an

SMS through GSM MODEM to his/her Mobile phone and Then authorized person sends message to the system then microcontroller switches the ON/OFF.

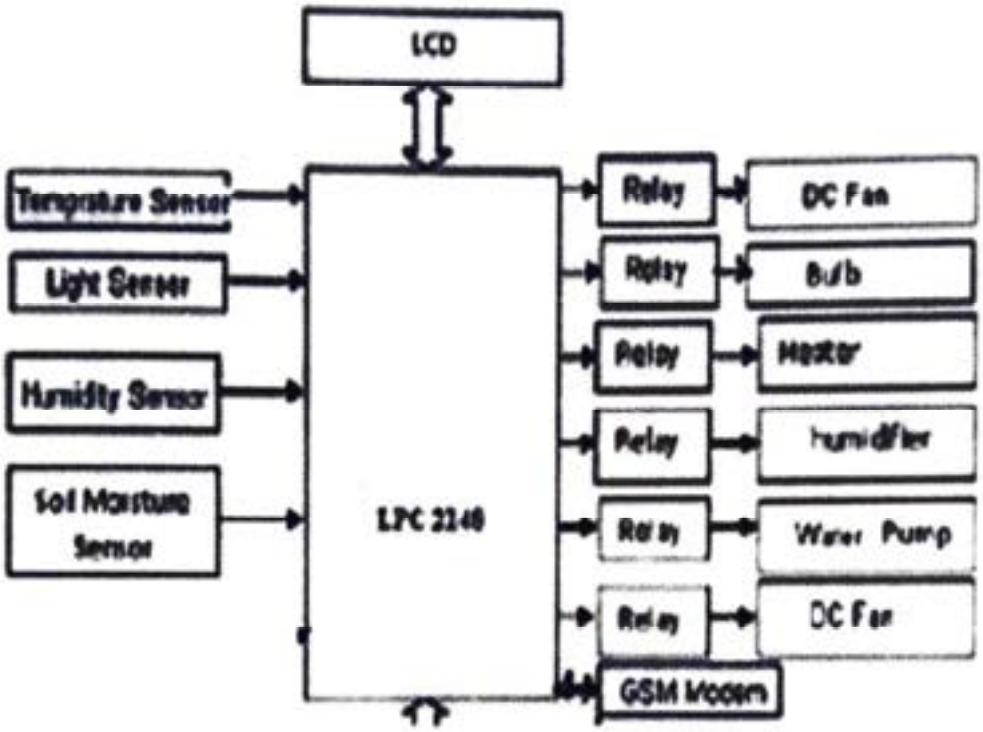

Figure 2.6 Functional block diagram

2.5.2.3 Software Development

The software for the system is developed in Embedded C and Visual Basic.

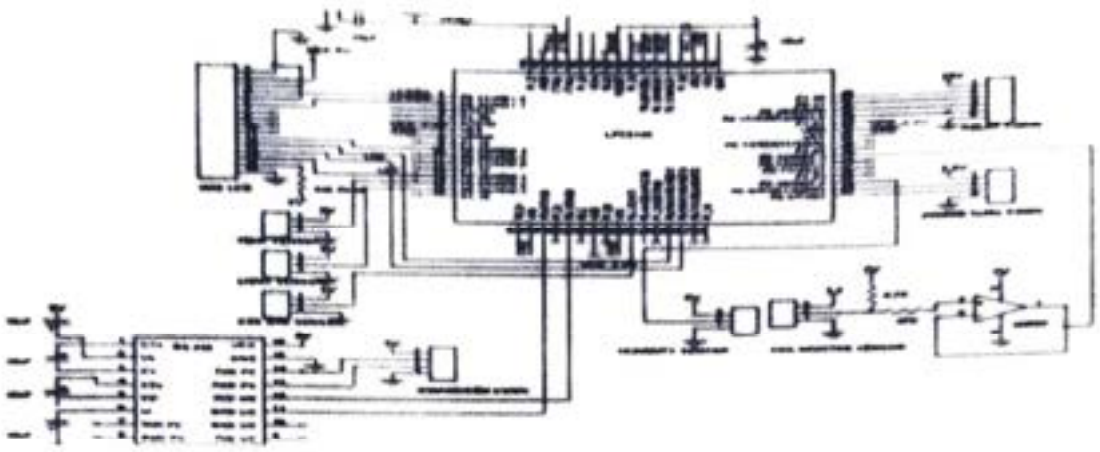

Figure 2.7 The circuit diagram of the entire system

2.5.3 Result

2.5.3.1 Temperature Sensor

The LM35 thus has an advantage over linear temperature sensors , as the user is not required to subtract a large constant voltage from its output to obtain convenient centigrade scaling. Features are as follows 1. Calibrated directly in ° Celsius (Centigrade) 2. Linear + 10.0 mV/°C scale factor 3. 0.5°C accuracy guaranteable (at +25°C) 4. Rated for full −55° to +150°C range 5. Suitable for remote applications 6. Low cost due to wafer-level trimming 7. Operates from 4 to 30 volts .

2.5.3.2 Humidity Sensor

These modules convert relative humidity to the output voltage. Humidity Sensor is designed to operate on DC 5 V, 0-60° c, 30-90° c RH , output voltage is DC 1.980 mv ± at 25 °c 60% RH.

2.5.4 Conclusion

The system has provided a low cost, remotely monitored and controlled solution for Greenhouse introduced. The use of a ARM Processor, GSM module, Sensors and different Controlling devices provide exciting possibilities. However as far as the Greenhouse applications are concerned this can be viewed as a low cost, customized Remote Measurement and Control system .The approach discussed in the paper is novel and has achieved the target to control Greenhouse remotely using the GSM SMS-based system satisfying user needs and requirements. GSM technology capable solution has proved to be controlled remotely. Hence we can conclude that the required goals and objectives of the system have been achieved.

2.5.5 Draw Back

Some arm processor clock frequencies and their speeds and memory are limited in such cases. The approach discussed in the paper is novel and has achieved the target to control Greenhouse remotely using the GSM SMS-based system satisfying user needs and requirements. GSM technology capable solution has proved to be controlled remotely. Hence we can conclude that the required goals and objectives of the system have been achieved.

2.6 Smart Greenhouse Monitoring using Internet of Things

Basrah Journal For Engineering Sciences, Vol. 17, No. 1, 2017.

2.6.1 Introduction

Before coming to the main topic let us discuss a little bit about green house and greenhouse effect. Green house is something related to a building or a place where small plants and vegetables are grown. And the area under green house is covered with glass or translucent plastic roofs. And this plays an important role for the vegetation in colder regions, because it is still very cold to take them to an outside environment. And now moving forward to discuss about the greenhouse effect. Greenhouse effect is simply a process in which various greenhouse gases entraps the infrared rays from the sunlight thus leading to increase of level of carbon dioxide which further helps in increasing the amount of chlorophyll and thus leading to impressive plant growth and yield. As we know that the green house contains the environmental parameters such as humidity, temperature, moisture, light etc. And sometimes what happen, due to the lack of knowledge among farmers, they are not able to perform their activities with accuracy.

They usually perform such activities on the basis of their own observation from the past and with their gut feeling which may lead to unexpected results most of the times. So in an order to cover it up and get more proper and accurate results for what activities a farmer should perform in different environmental condition this system is used. And the green house system helps in boosting the efficiency. And thus our system are based to perform such activities that are to monitor and control the sytem from a particular place which would take care of weather inside the green house It contains Aurdino UNO microcontroller, various sensors such as temperature sensors, humidity sensors, LDR sensors, smoke sensors etc and windows application for controlling green house and its parameters. When sensors reaches a certain threshold or critical value it will send the signal to microcontroller and required action will be taken automatically e.g fan will automatically start working when temperature inside the green house crosses the critical value.

2.6.2 Proposed Technique

2.6.2.1 Internet of Things

Internet of things is one of the most important technologies of the 21st century. It is trending everywhere. It is basically an environment in which simple physical objects are made capable enough to get accessed through internet. Internet of things could also be considered as collection of physical objects, controller, sensors, actuators and internet in appropriate and required manner. The Internet of Things permits articles to be detected and controlled remotely crosswise over existing system framework, making open doors for a more straight forward combination between the physical world and PC based frameworks and bringing about enhanced effectiveness, exactness and monetary advantage. It contributes to improved customer engagement, enhancing data collection, technology optimization and reducing waste.

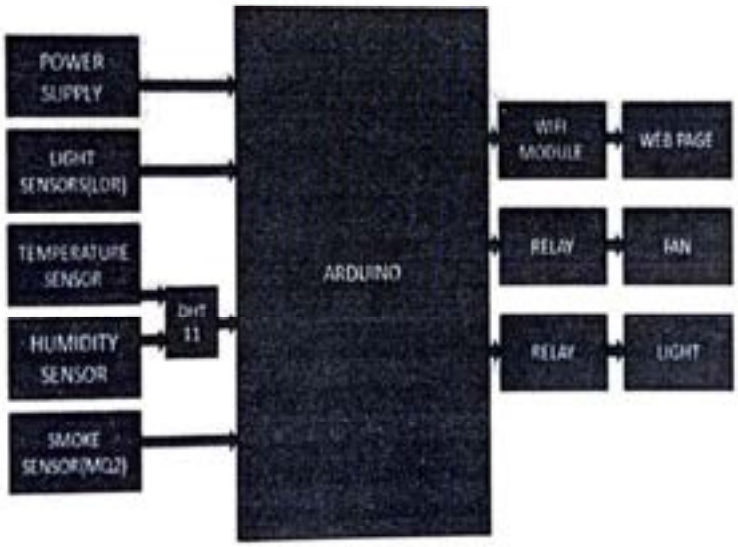

Figure 2.8 Block diagram

And we are making use of this technology in our proposed project. "Most physical parameters which are required in a nursery could be measured via programmed sensors. This includes temperature, light, soil dampness, and relative mugginess. Precipitation can likewise be distinguished, in spite of the fact that it is to some degree less normal. All the said physical

factors are inspected and put away electronically at general interims when something is evolving. In general, the estimations give a significant decent information yield photo of the physical part of the nursery edit framework. This proposed a commitment to the advancement of nursery observation.

2.6.3 Result

2.6.3.1 Light Sensors

LDR(Light Dependent Resistor) is the light sensor which is usually used for the purpose. Its main function is to monitor the intensity of light. It turns off the light when it need to save the power and turns on the light when light is required in the greenhouse.

2.6.3.2 Temperature Sensors

As the name suggests, these are used for monitoring the temperature and used to check whether the temperature is high or low inside the green house. And a critical value of temperature is fixed. And when sometimes the temperature inside the greenhouse reaches above the critical temperature level, the coolant is provided to cool down the temperature and bring it down to the favourable required temperature inside the green house.

2.6.3.3 Humidity Sensors

Humidity Sensors are basically used for measuring the relative humidity, which is the measure of vapour air to the total amount of vapour that could be held in the air for a given temperature.

2.6.3.4 DHT11 Sensors

We have used DHT11 sensors in our project. It is basically a humidity and temperature sensors which helps in getting digital output. It is quite reliable and has good stability and at the same time is cost effective. It comprises of three main elements- a resistive type humidity sensor, an NTC thermistor (for temperature measurement) and an eight-bit microcontroller which helps in converting analog signals from both sensors and helps in sending out digital signal.

2.6.3.5 Smoke Sensors

MQ2 smoke sensor has been used in this project which helps in detecting if there is some sort of leakage of any gases in the crop field or may be fire. It works on inverted logic. MQ2 smoke sensors has great sensitivity and has quick response time and at the same time is stable and has long life time.

2.6.4 Conclusion

Farming activities, even in urban zones are on an ascent as of late, in remarkable structures. Innovative advance makes the agrarian area develop high, which here is made by the IoT. The IoT will be playing a great role in changing the day to day life experience. And right now we are using limited number of parameters in our project but with the further advancement more number of parameters could be added for boosting the production. In future by building up a versatile application for IoT framework makes more adaptable to the people groups.

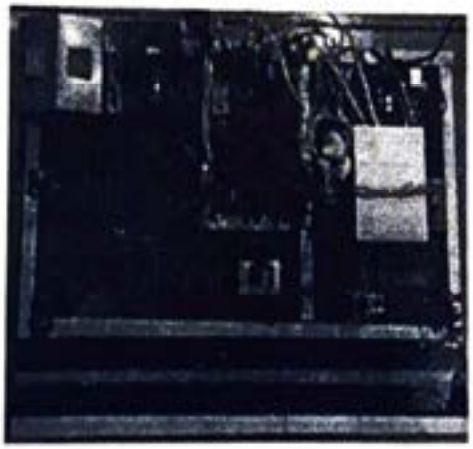

Figure 2.9 Greenhouse model

2.6.5 Draw Back

In this proposal they are used less number of parameters for the cultivation. This will be reducing the crop production.

2.7 Greenhouse Automation System using PSOC 3

International Journal Of Advanced Research In Electronics And Communication Engineering May-2011.

2.7.1 Introduction

Greenhouse Automation System is the technical approach in which the farmers in the rural areas will be benefitted by automatic monitoring and control of greenhouse environment. It replaces the direct supervision of the human. In this paper the different papers have been reviewsed and developed the proposed system based on the limitation in the present monitoring system. It also focuses on the Generic Architecture which can be applied for many other Automation Application.

Greenhouse is a building where plants are grown in a controlled manner. Nowadays due to urbanization and lack of land availability there is a great need to construct the Greenhouses which will be reserved mainly for growing crops.

Table 2.3 Components Specifications

References	Technology	Processor	Monitoring Station

2.7.2 Proposed Technique

The proposed architecture consists of the sensors, Psoc 3, relay circuit and the actuators which is as shown in fig. 1. The system consists of hardware and software requirements. The sensors used in this system are Temperature Lm 35DZ and for humidity SY- HS-220 sensor which is suitable for the greenhouse Environment.

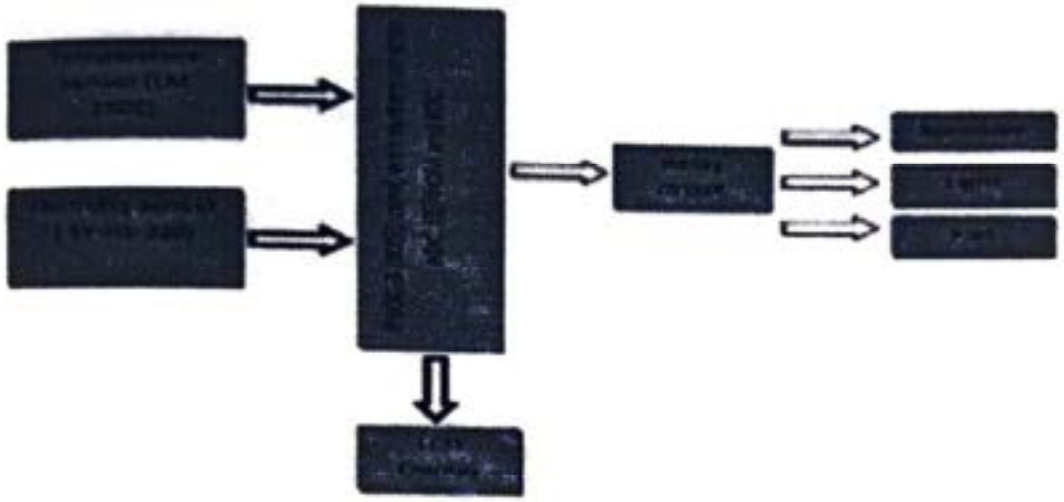

Figure 2.10 Block diagram of proposed architecture

2.7.2.1 Hardware Requiremnt

The hardware required for the Greenhouse control are:

Transducers: The transducer are the sensors which converts the physical quantity into electrical quantity. Two sensors used in the system are:

Temperature sensor(LM 35DZ) - It calibrates directly in degree celcius.

2.7.2.2 Software Requirement

The software required to implement the code is Psoc Creator. It has updated versions. For this system Psoc Creator 2.2 is used to code, Debug and program the device. The Communication between the PC and the device is done through the USB.

The Psoc Creator has 3 windows:

1) Schematic Window: The window where the components are dragged and dropped and connected through the wires.

2) Ports/Pin Assignment Window: The window where the pin number are assigned to the components and the system configuration can be changed.

2.7.3 Result

Psoc 3 Kit: It is the programmable system on chip which integrates analog and digital peripherals, memory and microcontroller(8051 core).

Relays: A relay is a simple electromechanical switch made up of an electromagnet and a set of contacts.

Actuators: It is a device which is used to control the parameter to the desired level. The actuators used in the system are: Fan Light Sprinkler.

Table 2.4 Crop details

Greenhouse Crop	Temperature Required(in Celcius)	Humidity Required(in RH%)
Rose	24 to 28	65-70
Capsicum	21 to 24	50-65

2.7.4 Conclusion

This paper shows the existing technology and processor used for the Greenhouse Applications. The Psoc 3 coding is done to set the limits of the parameters of the two crops. If the parameters are within the range then the value is displayed in the LCD. If it is not within the range the controller will turn on/off the actuators as per the requirements. Thus controlling the Greenhouse automatically without human intervention. Further the details can be updated to the user's mobile through GSM Modem interfaced with Psoc 3.

2.7.5 Draw Back

The main drawback of this paper is to control the two greenhouse at the same time. So that the parameters are not work for a set point level.

2.8 Plant Health Monitoring and Controlling of Environment in a Conservetris

Journal Of Information, Knowledge And Research In Electronics And Communication Engineering ,September-2000.

2.8.1 Introduction

Protection of plants in general and protection of crops against diseases in particular are important for better yield. Crop losses due to pathogens, pests, animals, and weeds are about 20 to 40% of global agricultural productivity . These losses can be reduced by monitoring health of the plant using technology and rising alerts upon detection of disease or when the disease crosses certain thresh hold. Image capturing and processing is one such technique to detect the health of the plant.

All plants and vegetation require certain conditions for their healthy growth. It is necessary to control the environmental conditions to make them optimum for the best growth of plants. Parameters, such as humidity, temperature, light intensity, soil moisture etc. are monitored and controlled to create the optimal environment. An automated management reduces manual intervention, labor cost, implements necessary action with least time delay.

2.8.2 Proposed Technique

Need to effectively grow a plant is of increasing demand in agricultural industry for improving the yield. In order to do so, it is important to monitor the plant during its growth period, as well as, at the time of harvest. Plants can suffer from viral, fungal and bacterial diseases. Here, bacterial and fungal affected leaf diseases are considered for experimentation as viruses produce no telltale signs that can be readily observed and often easily confused with nutrient deficiencies and herbicide injury. One method to detect these bacterial and fungal diseases is manual inspection and detection with the help of botanic experts; but manual detection of leaf diseases is much laborious and time consuming task. So, there is a need for machine based method to detect the plant diseases with better efficiency as compared to manual detection. Image Processing involves the steps of image acquisition, pre-processing (Image Contrast Enhancement), image segmentation, feature extraction, leaf disease detection &

classification. In the present work, image acquisition is performed by considering RGB color disease affected leaf image. Image pre-processing is performed to enhance the image quality using histogram equalization. Image segmentation is performed using kmeans clustering. Image feature extraction is performed to extract the features of leaf disease symptoms.

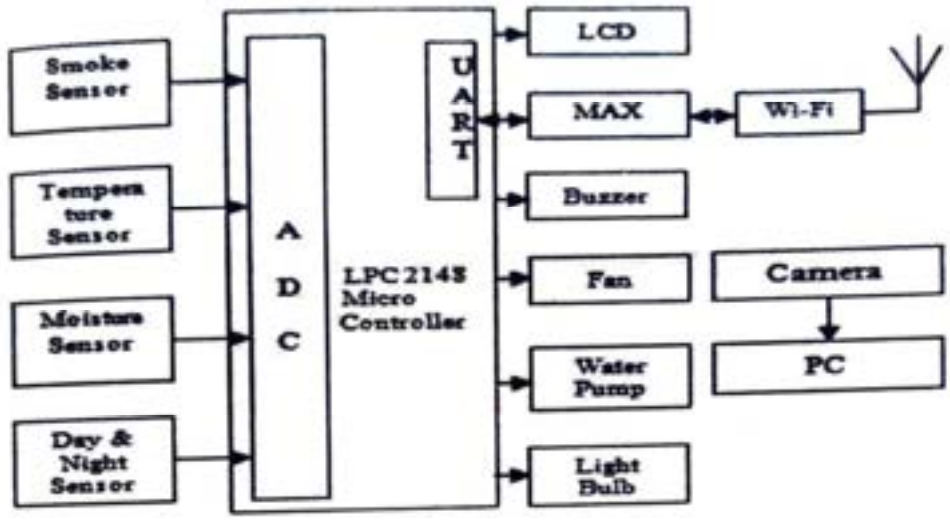

Figure 2.11 Block schematic of the experimental setup

2.8.3 Result

Percentage of disease in the selected image (=39%) The Smoke sensor (MQ2) is used to sense smoke or hazardous gases such as carbon monoxide, methane, propane, i-butane and carbon dioxide. Upon detection of any of the above mentioned gases, conductivity of the sensor increases, which is recorded by measuring the analog voltage. Change in measured voltage is a measure of concentration of the gas. If the measured value crosses the prefixed thresh-hold value then microcontroller activates a buzzer to alert the farmer.

LM35 temperature sensor is used to monitor the temperature of the conservatorium. This sensor measures temperature and produces output voltage which is linearly proportional to temperature in centigrade. Preferable temperature range for most of the plants is between 200C to 350C.

The test set up was installed in a conservatorium with tomato plants. A glimpse of the Conservatorium at GKVK and cultivation of Tomato plants inside the conservatorium. A prototype model developed in the present work used in the lab environment mimicking the GKVK conservatorium and small plants being grown inside it.

Figure 2.12 Diseased leaves

2.8.4 Conclusion

Developed system is very useful to monitor health of plant, take corrective action when the parameters of interest cross the specified ranges required. Integration of disease detection system and ambient control are unique feature of this work. ARM microcontroller can be explored to do the image processing part to eliminate the need for PC. Developed system can be installed with slight modifications anywhere to cultivate any type of crop. Automated controlling of devices eliminates the middleman and help farmers to produce high quality, high yield crops.

2.8.5 Draw Back

This proposal is for the identification of the diseases in the plant. But the pest is provided to the plants due to that the plant will get affected and influence to more diseases.

2.9 Different Technique of Greenhouse Remote Monitoring System

International Journal Of Advanced Research In Electronics And Communication Engineering.May-2018.

2.9.1 Introduction

Climatological condition monitoring is one of the most important aspects in agricultural production that has a direct impact on the productivity and maintenance of crop. A huge loss occurs every year due to damage of crops by various diseases caused by improper climatic conditions. Greenhouse is the advanced facility available in which we can control the climate to increase plant growth and avoid the effect of season changes on the plants. Greenhouse is playing a significant role in the production of out-of-season fruits, flowers and vegetables as well as high value and sensitive plants like capsicum. The purpose of greenhouse environmental monitor is to get the best climatic conditions (controlled temperature, humidity, light and level of carbon dioxide) for crop growth, increased crop yields, improved quality of crops, and regulated growth cycle of crops . Greenhouses are often used for growing flowers, vegetables, fruits, and tobacco plants. Most Greenhouse systems still use the manual system in monitoring the temperature and humidity. A lot of problems can occur not for worker but also affected production rate because the temperature and humidity of the greenhouse must be constantly monitored to ensure optimal conditions.

Table 2.5 Comparison of Zigbee Wi-Fi

Technology	Zigbee	Wi-Fi	GSM
Range	1-100+	1-100	wide
Source metrics	Reliability, Cost, power	Speed, Flexible	Cost
Application	Monitor & control	web, email	Data X^er

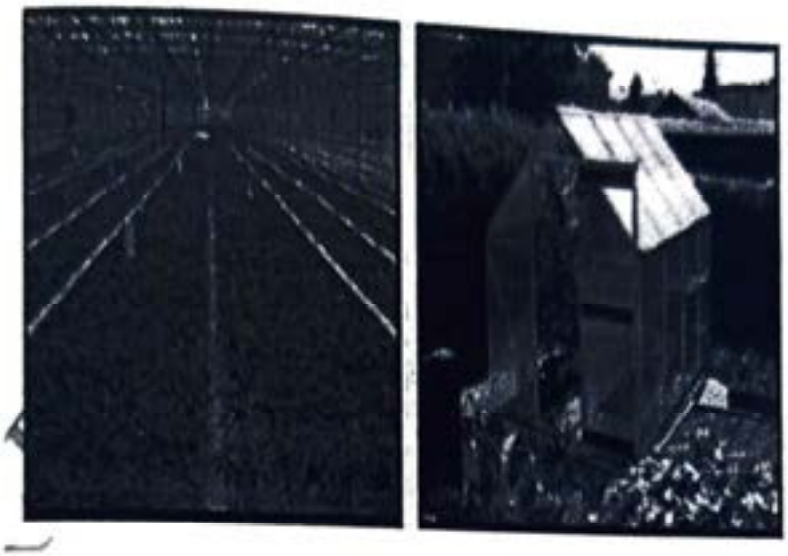

Figure 2.13 Greenhouse concept

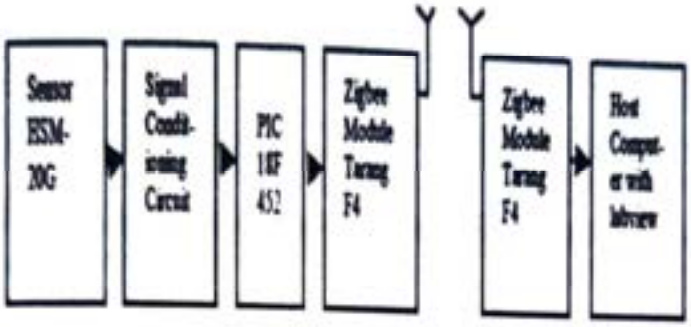
2.9.2 Proposed Technique

However, compared with wired data communication, ZigBee communication mode is more suitable for short distance communication inside greenhouse because its advantages, such as, no complicated wire, flexible networking, easy to upgrade. In recent years, Ethernet has been introduced in the remote information transmission technology for greenhouse because of its fast speed, general protocol, good expansibility and easy Internet integration, etc . Another wireless sensor GSM which has developed rapidly in recent years. Short Message Service of GSM is a value-added service based on data packet switching. Because the GSM network can be interconnected and roamed all over the country, it has strong network ability, the users has no need to organize another network. The coverage of the network is improved and expensive network building and maintenance cost can be saved for users. At the same time, the number of its users is not limited. GSM network provides a strong platform for remote data transmission and monitoring the communication of equipment, it is an important method of wireless remote monitoring system. A wireless sensor network (WSN) consists of spatially distributed autonomous sensors to monitor physically or environmental conditions, such as temperature, sound, vibration, pressure, motion or pollutants and to cooperatively pass their data through the network to a main location . WSN can be used in some special situation for signal collection,

processing and transmitting. Wireless communication can be used to collect the measurement and to communicate between the centralized control and the actuators located in the different parts of the greenhouse. Moreover, it is easy to relocate the measurement points when needed by just moving sensor nodes from one location to another within a communication range of the coordinator device. WSN maintenance is also relatively cheap and easy .



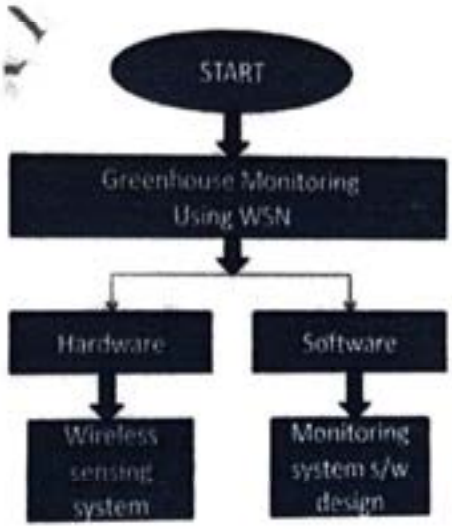


Figure 2.14 Block diagram of wireless sensing system

2.9.3 Result

The network of field data acquisition and transmission is built on the wireless sensor network and RS232 bus. The sensor nodes arranged in the greenhouse sample temperature, soil moisture, humidity and other information. Monitoring software of system server is the most critical part in the greenhouse environment information monitoring system, which is used for

dealing with the users and obtaining information of wireless sensor. The main function of monitoring software consists of parameter setting, display, query, analysis, report processing and alarm for real-time data, online real-time monitoring, real-time curve display, and remote real-time communication.

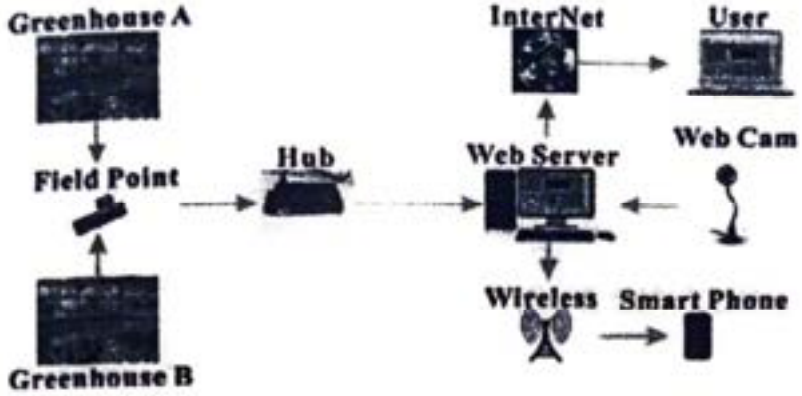

Figure 2.15 Greenhouse environment and control architecture

2.9.4 Conclusion

A review of the literature on environmental monitoring systems elucidates that the existing systems suffer from several drawbacks and thus modifications are being continuously suggested. The available environmental monitoring systems have limitations as unstable system; all parameters cannot be measured simultaneously. So there is a need for a system which can measure environmental parameters simultaneously; in addition, it should be energy efficient, economical, robust, and easy to operate.

2.9.5 Draw Back

The aim of research work is to design, develop and implement a sensor-based wireless communication system to monitor and control the greenhouse parameters using virtual instrumentation. Data analysis, control solutions and more complex network setups will be left to be the main directions of future work.

2.10 Automated Greenhouse Monitoring System

Basrah Journal For Engineering Sciences, Vol. 17, No. 1, 2017.

2.10.1 Introduction

In a world where everything can be controlled and operated automatically, but there are still few important sector in our country where automation has not be adopted not be put to a fully fledge use. perhaps because of several reasons. One such a reason is cost and one such field is agriculture. Agriculture has been one of the primary occupation of man since early civilization part and horticulture sectors. In our country, as they can be used to grow plant under controlled climatic parameters which directly or indirectly governed the plant growth and hence they produced. Automatic is process control of industrial machinery and a process they by replacing human operators. This system consist of various sensors namely soil moisture, temperature and light. This sensor sense various parameter temperature, soil moisture, and the light intensity and are then send to PIC microcontroller AT89S52. The microcontroller constantly monitors the digitalized parameter of various sensor and verify them with the predefined threshold values under check if any corrective action to be taken for contain at that instant time in case such situation arises it activate the actuator to perform a controlled operation.

2.10.2 Proposed Technique

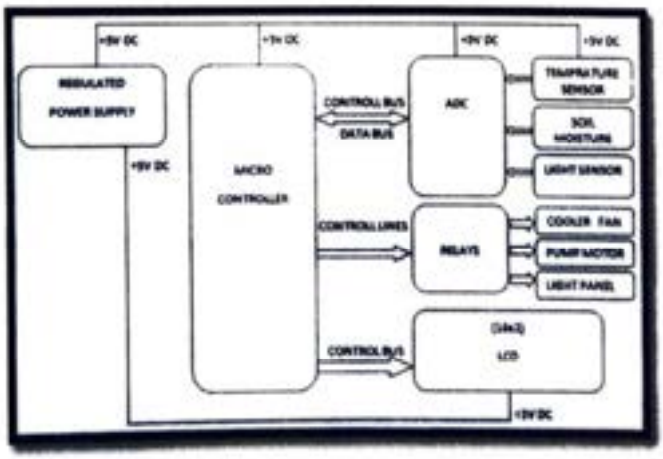

Figure 2.16 Block diagram of the system

2.10.2.1 LCD (Liquid Crystal Display)

LCD screen is an electronic display module and find a wide range of applications. A 16X2 LCD display is very basic module and is very commonly used in various devices and circuits. These modules are preferred over seven segments and other multi segments and other multi-segment LEDs. The reason being: LCDs are economical; easily programmable; have no limitation of displaying special & even custom characters (unlike in seven segments), animations and so on. A 16X2 LCD means it can display 16 characters per line and there are 2 such lines. In this LCD each character is displayed in 5X7 pixel matrix. These LCD has two registers, namely, command and data.

2.10.2.2 Relay

A relay is an electromagnetic switch operated by a relatively small electric current that can turn on or off a much larger electric current. The heart of a relay is an electromagnet (a coil of wire that becomes a temporary magnet when electricity flows throught it). You can think of a relay as a kind of electric lever: switch it ON with tiny current and it switches on (leverages) another appliance using a much bigger current. Why is that useful? As the name suggests, many sensors are incredibly sensitive pieces of electronic equipment and produce only small elctric currents. But often we need them to drive bigger pieces of apparatus that use bigger currents. Relays bridge the gap, making it possible for small current to activate larger ones.

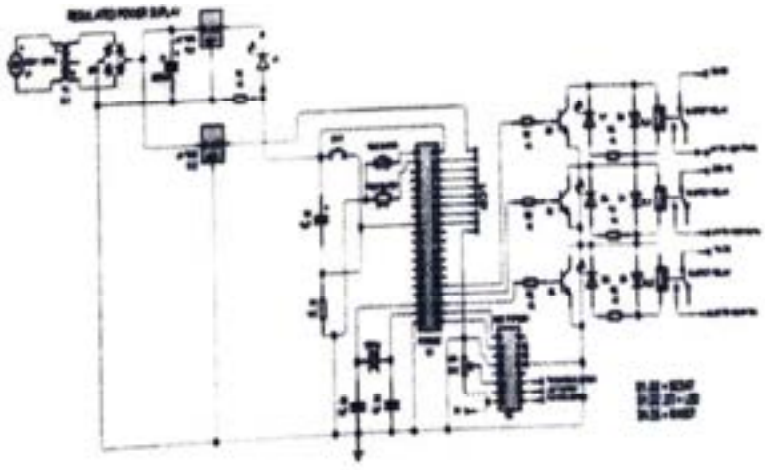

Figure 2.17 Circuit diagram of automatic greenhouse monitoring system

2.10.3 Result

This section consists of various devices like cooler fan to reduce the atmospheric temperature, water pump to insrease water content in the soil, light pannel to compensate for lack of sunlight inside the green house. These are actuated by relays controlled by the microcontroller 89S52.

2.10.4 Conclusion

Automated greenhouse monitoring system consists of various sensor namely soil moisture sensor, temperature sensor, and light sensor. These sensors sense various parmeters soil moisture, temperature, and light intensity and are then sent to the microcontroller 89S52 and control action taken by the microcontroller to compare with preset values. Automated greenhouse monitoring system eliminates risk of green house not bieng maintained at specific environmental conditions due to human error and labour cost can be reduced and it is eco friendly. Pests are eliminated by this system and also the quantity of yield can be increased.

2.10.5 Draw Back

In this proposal they were used conventional energy resource. The components in a greenhouse consume more power. So the components are get easily heated. In future we need to overcome these problems

2.11 Summary of Literature Review

S.NO	TITLE	TECHNIQUE	DRAWBACKS
1	Remote control system for greenhouse environment using mobile devices	Wireless sensing and control technology	While we use WIFI it covers only a short distance
2	Plant health monitoring and controlling of environment in a conservation	Image processing	automated controlling of devices eliminates the middleman and help farmers to produce high quality , high yield of crops.
3	IoT based intelligent greenhouse monitoring and scontrol system	FUZZY Controller	Due to LDR ,the overall system performance is overshot . Because it produces un precise result.
4	Smart Greenhouse monitoring using IOT	IOT	less number of physical objects are assigned with IP address.
5	Greenhouse monitoring and automation using GSM module	GSM	System may occur at high cost.

6	Different techniques of greenhouse remote monitoring system	WSN.ZIGBEE.GSM	The system become unstable due to more components and all the parameters are not possible to measure.
7	Automated greenhouse monitoring and control system	Microcontroller	Power consumption is very large because all the sensors uses the conventional energy resources.
8	Greenhouse monitoring and controlling using ARM	GSM	Some arm processor clock frequencies and their speeds and memory are limited in such cases.
9	Arduino based automatic plant watering system	Automatic watering plants	Expensive technique.
10	Greenhouse automation system using PSOC3	PSOC3 KIT	Due to monitor and control of different greenhouse system the power consumption is required more than normal greenhouse.

CHAPTER 3

THEORETICAL BACKGROUND

3.1 Introduction

We live in the world where everything can be controlled and operated automatically, but there are still a few important sectors in our country where automation has not been adopted or not been put to a full-fledged use, perhaps because of several reasons one such reason is cost. We live in a world where each and everything can be controlled and operated automatically, but still there are still a few important sectors in our country where even now automation has not been adopted some cases has not been put to a full-fledged use, perhaps because of certain reasons. The increase in living standards and higher consumer demands have increased pollution of the air with CO2 and other greenhouse gases; particulate matter of water along with a variety of chemicals, nutrients, and oil spills; and of the soil owing to the disposal of hazardous wastes, application of herbicides and pesticides, and disposal of non-biodegradable materials, etc.

3.2 Proposed Block Daigram

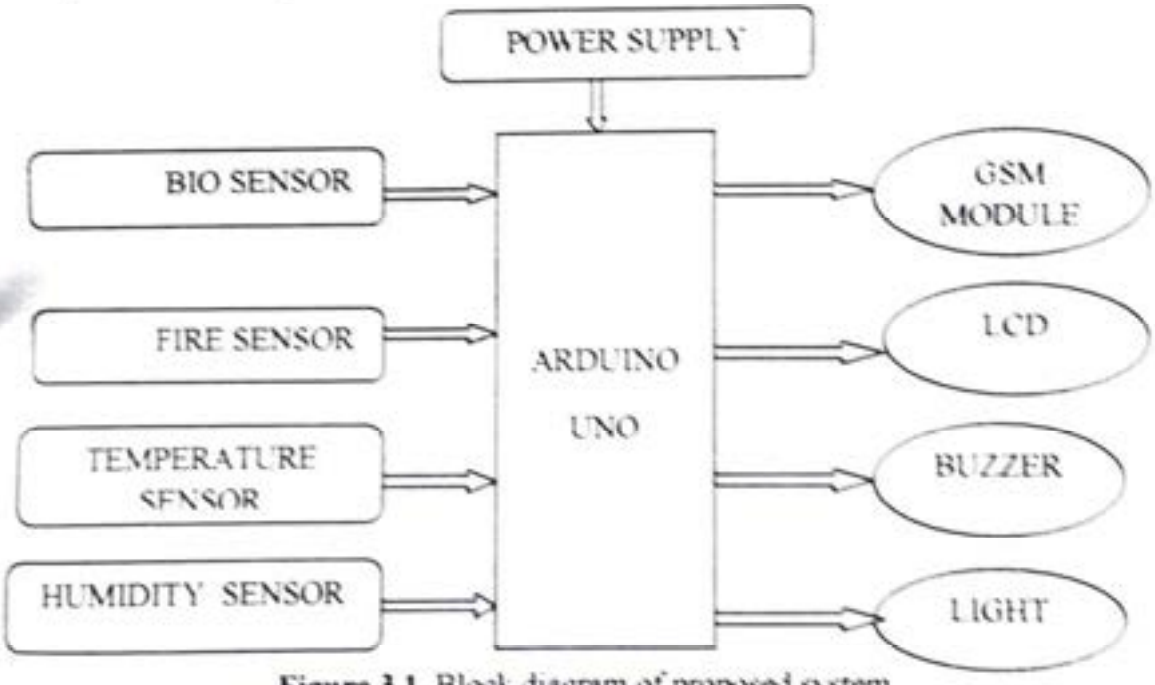

Figure 3.1 Block diagram of proposed system

3.3 Hradware Requirement

3.3.1 Arduino UNO

The arduino Uno is a microcontroller board based on the ATmega328, It has 14 digital input/output pins, 6 analog input, a 16 MHZ crystal oscillator, a USB connection, a power jack, an ICSP header, and a reset button. The Uno differ from all preceding boards in that it does not use the FTDI USB to serial driver chip."UNO" means one in Italian and is named to mark the upcoming release of arduino 1.0. The Uno is the latest in a series of USB Arduino boards and reference model for Arduino platform. The Arduino Uno can power via the USB connection or with external power supply. External power can come either from an AC to DC adapter or battery.The board can operate on an external supply of 6 to 20 volts. If supply with less than 7v, however, the 5v pin may supply less than five volts and the board may be unstable. The Ttmega328 has 32 KB of flash memory for storing code .It has also 2KB of SRAM and 1KB of EEPROM. The Arduino software includes a serial monitor which allows simple textual data to be send to and from the Arduino board, The RX and TX LEDs on the board will flash when data is being transmitted via the USB to serial chip and USB connection to the computer. A Software Serial library allows for serial communication on any of the UNO's digital pins, the arduino software includes a wire library to simplify use of the I2C bus. Arduino is open source hardware and software, which are license under the GNU lesser General public license, which is permitting the manufacture of Arduino board and software distribution by anyone.

Figure 3.2 arduino uno

3.3.2 Soil Moisture Sensor:

The two copper leads act as the sensor probes. They are immersed into the specimen soil whose moisture content is under test. The conductivity of soil depends upon the amount of moisture present in it. It increases with increase in the water content of the soil that forms a conductive path between two sensor probes leading to a close path to allow current flowing through.

Figure 3.3 Soil Moisture Sensor

3.3.3 LDR Sensor

The light sensor is extremely sensitive in visible light range. With the light sensor attached to the system when the surrounding natural lights are low, it displays the digital values.

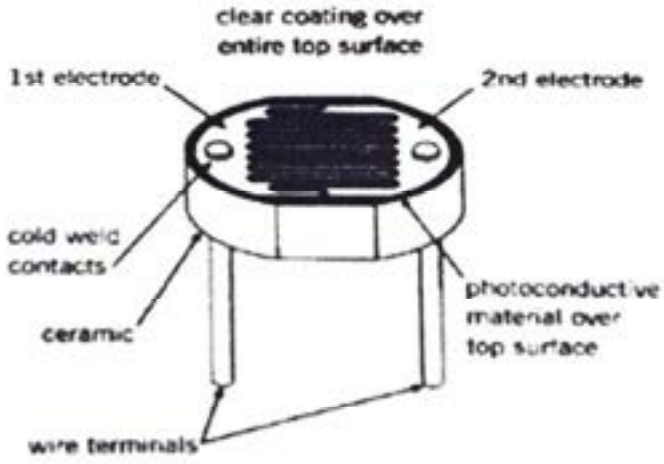

Figure 3.3 LDR Sensor

Figure 3.3 LDR Sensor

3.3.4 Humidity Sensor

Humidity sensor is used for sensing the vapours in the air. The change in RH (Relative Humidity) of the surroundings would result in display of values.

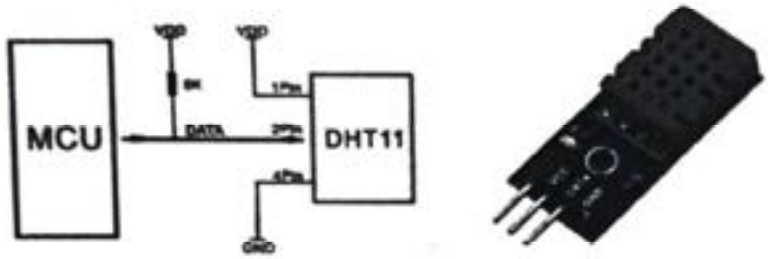

Figure 3.4 DHT11 Sensor

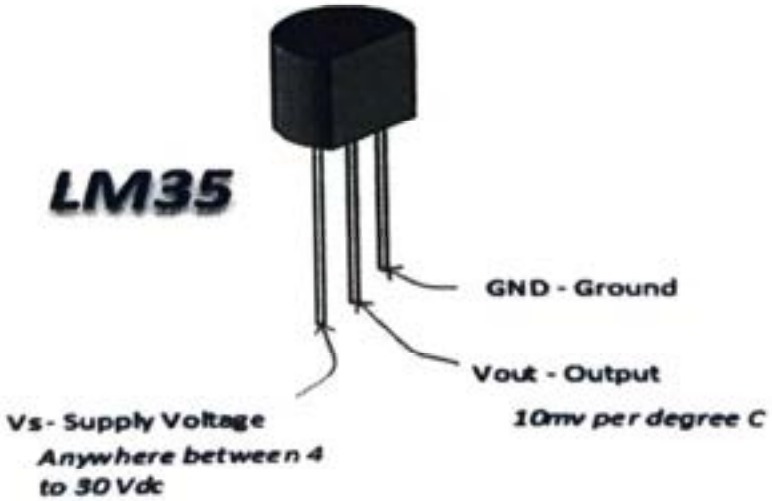
3.3.5 Temperature Sensor

If the temp exceeds beyond the limit set then a fan will be automatically switched ON as a coolant to reduce the temp. When it reaches the desired temp the fan will be switched OFF automatically with the help of a relay. But if the temp decreases bellow the optimum temp a bulb as a heater will be switched ON to set the temp within the desired range.



CHAPTER 4

SYSTEM SPECIFICATIONS

4.1 Software Implementation

The software part programming through Arduino Uno software (IDE). It is easy to write code and upload it to the board. C ,C++ language are used for programming.

4.2 Arduino Uno

The **Arduino `Uno** is an open-source microcontroller board based on the Microchip ATmega328P microcontroller and developed by Arduino.cc. The board is equipped with sets of digital and analog input/output (I/O) pins that may be interfaced to various expansion boards (shields) and other circuits. The board has 14 Digital pins, 6 Analog pins, and programmable with the Arduino IDE (Integrated Development Environment) via a type B USB cable It can be powered by the USB cable or by an external 9-volt battery, though it accepts voltages between 7 and 20 volts. It is also similar to the Arduino Nano and Leonardo. The hardware reference design is distributed under a Creative Commons Attribution Share-Alike 2.5 license and is available on the Arduino website. Layout and production files for some versions of the hardware are also available.

The word "uno" means "one" in Italian and was chosen to mark the initial release of the Arduino Software. The Uno board is the first in a series of USB-based Arduino boards, and it and version 1.0 of the Arduino IDE were the reference versions of Arduino, now evolved to newer releases. The ATmega328 on the board comes preprogrammed with a bootloader that allows uploading new code to it without the use of an external hardware programmer.

While the Uno communicates using the original STK500 protocol, it differs from all preceding boards in that it does not use the FTDI USB-to-serial driver chip. Instead, it uses the Atmega16U2 (Atmega8U2 up to version R2) programmed as a USB-to-serial converter.

4.3 Background

The Arduino project started at the Interaction Design Institute Ivrea (IDII) in Ivrea, Italy. At that time, the students used a BASIC Stamp microcontroller at a cost of $100, a considerable expense for many students. In 2003 Hernando Barragán created the development platform Wiring as a Master's thesis project at IDII, under the supervision of Massimo Banzi and Casey Reas, who are known for work on the Processing language. The project goal was to create simple, low-cost tools for creating digital projects by non-engineers. The Wiring platform consisted of a printed circuit board (PCB) with an ATmega168 microcontroller, an IDE based on Processing and library functions to easily program the microcontroller. In 2003, Massimo Banzi, with David Mellis, another IDII student, and David Cuartielles, added support for the cheaper ATmega8 microcontroller to Wiring. But instead of continuing the work on Wiring, they forked the project and renamed it Arduino. Early arduino boards used the FTDI USB-to-serial driver chip and an ATmega168.

CHAPTER 5

RESULT AND DISCUSSION

5.1 Result

In this project we are using IOT technology and GSM module technology .The sensors are deployed in the greenhouse which senses the current climatic conditions ,moisture of the soil in the greenhouse. The sense data is in analog form so that is converted in ADC circuit .ADC converter using to convert analog to digital form and transmit to a microcontroller computes the values and senses and send to the computer. sensor will sense the environment of the greenhouse and give all the information to the computer and according to the information computer will notify the about all the climatic condition to the mobile application .when it exceeds the above the threshold level it give alert through GSM module to mobile devices.

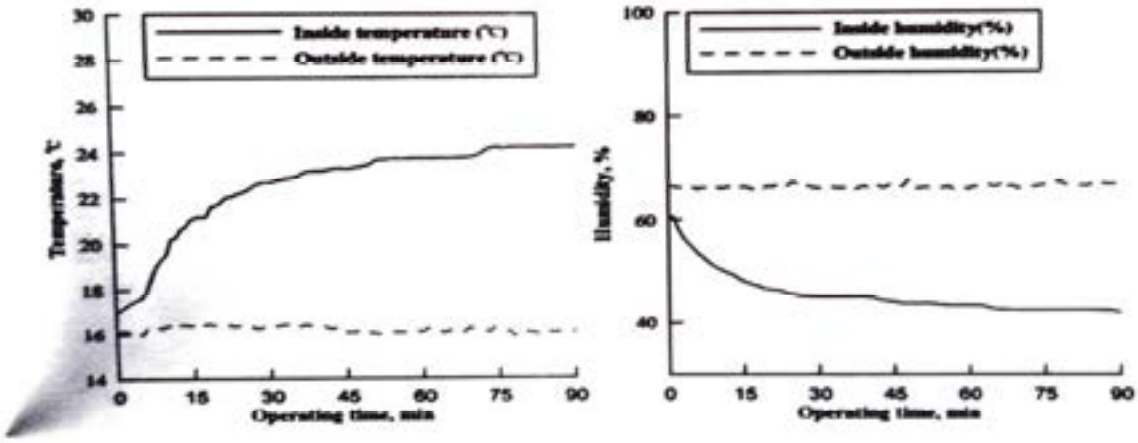


Figure 5.1 Temperature and Humidity by operating time

5.2 Discussion

The report is consist of the work done for the proposed technique of this project. In this, the proposed block diagram components are explained in detail. Then the software part of the project is Arduino IDE. With the help of this software we can load the program in the arduino board. This will identify the set level and done all the work of the greenhouse in automatic manner.

CHAPTER 6

WORK TO BE DONE IN PHASE II

For this project in phase II we are going to growth a plant in a controlled manner in a greenhouse. The temperature, moisture, humidity, light sensor's are placed in the greenhouse. The coding for the greenhouse system is loaded in the arduino board. Then the a level is set for the each sensor when the process reaches that level the parameters are ON automatically. In phase II hardware kit is placed for model.

ABSTRACT

The proposed system is cloud based forest fire alert system using IOT technology. The most common hazard in forest fire Accident are themselves destroy the forest and great threat for wildlife and peoples. The number of trees has reduced drastically so the forest are creates an unhealthy environment for animals to survive in the forest. Forest covers 31% of the world and 21% of the India. It has found in a survey that 80% of losses are caused due to fire. This project of a system fire was detected early stages. It was tracking and alarming for protection of trees against forest fire. Now IOT (Internet of things) devices and cloud based to forest fire alerting system. If cloud can used to storing the information of data to monitoring the different environmental variables such as temperature, smoke, moisture of the forest. So finally to prevent the fire to spread over a huge area and precaution the forest. In the advancing world, it is very crucial to protect our environment. The fire cause serious change and disturbance to wildlife and human life. In wild animals are most affected and die also known for forest fire. If forest trees also burned to affect atmosphere, environment. This fire made naturally and man-made. So this project need to prevent and pre-cautions from forest fire. In order to achieve the best fire detection result with faster time to detect the temperature variation. When temperature sensor used to measure the temperature variation. Smoke sensor is a device that dense smoke, typically as an indicator of fire. Arduino at mega 328p used to control and monitor the activities. Cloud is a storage purpose to use him. Because each and every second to monitoring the environment condition data can be stored. IOT Device to interface with Arduino and cloud.so finally fix the monitoring system done in nearby forest office station. The detail about the system is connected with a computer system monitored by the officer.

CHAPTER 1

INTRODUCTION

1.1 Introduction

Fire is very deadly and it leads to loss of human life and property. Fire detection systems are necessary to reduce the destruction of personal belongings and caused by fire both man made and induced. Fire accidents claim roughly 65 victims every day. A total of 1.21 lakh fire accidents occurred between the years 2010 and 2014. Forests generate water supplies, biodiversity, pharmaceuticals, recycled nutrients for agriculture and flood prevention, and are central to the transition towards a Green Economy in the context of sustainable development and poverty eradication. The over utilization of ground water has drastically reduced the ground water level in the last 15 years. Also we should develop some new methods that use the renewable sources of energy. The development of these new techniques are going to reach our goal of sustainable development as well as to cut off the emission of greenhouse gases to a minimum level. The Internet of Things is a collection of sensor, actuators, software, electronics embedded with home appliances, physical devices and vehicles which connect with each other to connect and exchange date which helps in increasing the efficiency of everyday appliances using computer based systems. IoT is just another way to make everyday life easier for humans by developing smart devices. IoT devices have increased 31% per and was at 8.4 billion in the year 2017. IoT involves connecting objects beyond the range of standard devices which are used for everyday purposes. In Arduino Uno Atmega328p used to interface the LCD Display and the information .In this paper we have developed a cloud based forest fire alert system using IoT. The wireless mobile device to connect the cloud, then monitoring and exact location find it. Gas sensor, it detects the presence of any flammable gas like CO2. Temperature sensor, detects of there is any unusual change in the temperature. The connectivity and compilation.

CHAPTER 2

LITERATURE SURVEY

2.1 Forest Fire Detection and Alerting System

Michel Owayjan, George Freiha, Roger Achkar," Forest Fire Detection and Alerting System" 17th IEEE Mediterranean Electro technical conference, Beirut, Lebanon 13-16 April 2014.

2.1.1 Introduction

As the human technology moved further, the risk of natural and man induced catastrophes increase exponentially. One of the most dangerous disasters is fires. In addition to its direct danger on human's lives, fire consumes forests where trees that provide humans with oxygen are destroyed. The risk of fire has increased due to the problem of global warming which appeared in the 1980s. Forest fires represent a constant threat to ecological systems, infrastructure and environmental aspects of a community. This gives rise to the urgent need to detect forest fires as fast as possible. This paper highlights the powerful feature of wireless sensor networks as a potential solution to the challenge of early detection of forest fires. The device presented makes use of various sensors attached, solar recharging mechanism, and wireless data transmission, to fulfill the task in question. These collected data are transmitted to a near central unit where they are analyzed and then uploaded to an online website which contacts the Civil Defense unit if necessary. This website is accessible by the specific authorities in order to take early actions in case of any alert. It is worth mentioning that this system is efficient and green; thus, enforcing the need for its creation.

2.1.2 Technique

The box contains different types of sensors. These units communicate wirelessly and send the data collected from all the sensors to a base station that contains a central computer and an Internet Connection. The data collected will be uploaded in a database from the base station computer to an online website; this database compiles the history of the data that has been gathered from all the installed systems across the forest. The main part of this design is how to process the sensor outputs, send the data to the central unit to check if there is a fire. Thus, the Easy Bee module must include a microcontroller to collect the data and put them in a string, and a communication medium to send them. The microcontroller used in the system is the PIC16F877A, which is the main component responsible for acquiring, sending, and receiving data. The main part of this design is how to process the received string and send the data to the computer where custom software will analyze it to check if there is fire. Thus, the circuit must include a microcontroller to collect the data coming from the Zig Bee and redirect them to the computer. The microcontroller used in the system is the same as the one used in the transmitter part, PIC16F877A. Since Zig Bee is a mesh network that can communicate with other modules having the same protocol, the same module was used in the receiver unit.

2.1.3 Drawbacks

- Short range
- Low data speed
- High maintenance cost

2.2 Forest Fire Detection using Wireless Sensor

Harjinder Singh," Forest Fire Detection using Wireless Sensor", International Journal of Scientific & Engineering Research, Volume 7, Issue 7, July-2016.

2.2.1 Introduction

The advancement in human technology the risk of natural and man induced catastrophes increased exponentially. One of most dangerous disaster is forest fire. The forest fire represents continuous threat to species of flora as well as fauna. This paper highlights the powerful feature of wireless sensors for forest fire detection. The sensor data is collected using Arduino development board and transmitted to base station wirelessly.

2.2.2 Technique

At a particular time interval if the temperature 'T' which is output of temperature sensor is below the threshold value will indicate that there is no forest fire. These temperature values along with the value of humidity and smoke will be transmitted in real time to base station so as monitor the forest environment condition continuously. Now if the temperature becomes greater than the normal at the particular time an alert is send to base station through call and SMS.

2.2.3 GSM Module

GSM (Global System for Mobile Communication) is a digital mobile telephony that is widely used across the world. GSM uses a variation in time division multiple access (TDMA) which allows different users to share same frequency channel by dividing signal into different time slots. The GSM used in this project is SIM-300 GSM module. It is a tri band based engine that works on frequencies 900 MHz, 1800 MHz and 1900 MHz. In India at a frequency of 900 MHz. SIM-300 is used to make a call and send SMS to base station when temperature exceeds threshold value, humidity, smoke value.

2.2.4 Draw backs

- It is not fully secure.
- Short battery life.

2.3 Forest-Fires Surveillance System Based On Wireless Sensor Network

Mr.Lalit Patil, Miss.Divya Chopda, Miss.Prachi Jadhav," Forest-Fires Surveillance System Based On Wireless Sensor Network", Mr.Lalit Patil.et al. Int. Journal of Engineering Research and Applications ISSN: 2248-9622, Vol. 6, Issue 4, (Part - 2) April 2016.

2.3.1 Introduction

Forest fires cause billions of Rupees in damage to property and the environment every year. To combat forest fires effectively their early detection and continuous tracking is vital. With the help of advanced Wireless sensor network techniques many methods have been developed to detect a forest fire in remote regions. Fire fighters need frequent and high-quality information updates of a fires development in order to conduct an effective and safe firefighting mission. Because forest fire monitoring is a difficult task. Forest cover is an important input variable for assessing changes to carbon stocks, climate and hydrological systems, biodiversity richness and other sustainability science disciplines. Despite incremental improvements in our ability to quantify rates of forest clearing, there is still no definitive understanding on global trends. Without timely and accurate forest monitoring methods, policy responses will be uninformed concerning the most basic facts of forest cover change. Results of a feasible and cost effective monitoring strategy are presented that enable timely, precise, and internally consistent estimates of forest. Taking in to consideration all this reasons we are designing a system that will help nature savior by help of advance technology.

2.3.2 Technique

Catching of fire in many of the forest is being detected lately. And which basically causes wide amount of disaster to nature. In prior system weather condition (e.g. clouds) seriously decrease the accuracy of satellite-based forest fire detection as the limitations led by the long scanning period and low resolution of satellites. So our idea behind this problem is to get the early detection of fire in the forest before it spreads to the entire forest. We will be

using different types of sensors i.e. smoke sensor, humidity sensor, and temperature sensor. Which will immediately recognize the amount of fire and will send the required data to the forest officer in this way we are trying to help the nature from destroying it. There are two main unites of hardware. In which one is Forest section which will be placed in the forest having Microcontroller unit to which different units are connected. Sensors are used to sense i.e smoke sensor is used to sense the smoke generated by the forest fire. As there occurs change in temperature when fire in been generated so for that purpose temperature sensor is used. Humidity sensor is used to since the humidity in the environment after changing the temperature. For data transmission purpose RF module/zigbee is used that sends the data to the receiver side but to send the data from microcontroller unit to the RF module/Zigbee we require standard RS232 cable. Entire circuit will work on 5v power supply. From the receiver side decoding is done of the data and the signal transmitted through serial communication cable.

2.3.3 Drawbacks

- Short range communication
- Low data speed
- Blur or accuracy is less.

2.4 Design and Development of Automatic Fire Detection Using SMS and Voice Alert System

Sathishkumar.R, Vinothkumar.M, Devaraj Varatharaj," Design and Development of Automatic Fire Detection Using SMS and Voice Alert System", International Journal of Scientific & Engineering Research, Volume 7, Issue 5, May-2016.

2.4.1 Introduction

In this work a review of existing fire-detector types has been carried out along with the development of a low cost, portable, and reliable PIC microcontroller based automated

fire voice alerting system for remotely alerting any fire incidents in industrial premises. During fire emergency response operations, establishment and utilization of situational awareness are of essential importance, enabling first responders, especially incident commanders, to better assess changing on-scene situations and make informed decisions. To keep in mind of the above mentioned situations, our proposed system is designed to alert the distant property-owner efficiently and quickly by sending short message (SMS) via GSM network and voice alerting system. This system guides the usage of Fire extinguisher during the fire accidents. A Linear integrated LM35 sensor detects Fire beyond preset value. The sensor units are connected via common data line to PIC microcontroller. A GSM kit based network module, capable of operating in standard GSM bands, has been used to send alert messages. Therefore the system is called eco-friendly system since the system automated in such a way to replace the conventional practices during fire accidents. The proposed system describes the nature of occurrence of fire and the system used to control them in the source**.**

2.4.2 Technique

In this system the fire is detected with the help of LM35 FIRE DETECTION sensor. Sensor sends a signal to microcontroller. In the next step microcontroller sends an active signal to other externally connected devices. The efficiency and memory of the microcontroller can be increased if microcontroller is used in place of 16f877a. Multiple SMS can be send by changing programming GSM module and VOICE alert. To change the SIM card we have to make changes in program. GSM module sends the information to the mobile phone in the form of sms to the customer and mean while alerts the entire industry through voice recorder. Voice recorders guide the employees in the correct direction and give instructions for the operation of fire extinguisher. Commercial security devices issue a signal to a fire alarm control panel as part of a fire alarm system, Arduino software to developing the code for sending an SMS to safety officer or concerned authority person. SMS based Fire Alarm system are very useful in remote locations where human interaction is limited. Voice Alert system combines fire alert system. In this system digital voice technology is used today. Transmitters and a remote Receiver/Speaker Base Unit. When a zone is breached, a signal is sent up to 50 feet to the remote Base Unit.

2.4.3 Drawbacks

- Cannot interface high power directly.
- More complex.
- It is generally used in micro equipment.

2.5 Forest Fire Detection System

Dr.S.Praveenchakkaravarthy, J.Nancy, V.S.NaveenKumar." Forest Fire Detection System", International Journal of Recent Trends in Engineering & Research (IJRTER) Conference on Electronics, Information and Communication Systems (CELICS'17) Special Issue; March – 2017.

2.5.1 Introduction

Forest fire also known as bush fire or hill fire is an uncontrolled fire occurring wild or forest areas. It is very important to detect these kinds of fires as early as possible so as to prevent the damage from it to ecological system. The land were forest is burnt it becomes impossible to grow vegetation over there. This is because soil becomes water repellent and accepts no more water, leading to reduction in ground water level. Fire causes huge loss of lives and properties every year. Some of the main causes are erratic climatic change, prolonged dry season, low winter rainfall etc. but the argument is these conventional fire extinguishing systems are not enough to take prompt action during fire and save life. Traditional manual system does not ensure 24/7 monitoring from fire protection. Moreover, existing fire protection system could spread panic inside the whole building since it does not announce the location of fire or intensity. It only raises alarm whenever fire is detected at any place. Frightened people could starts to run away haphazardly. As a result buildings full of workers in the factories women, children could be smashed by the outgoing pressure of the frightened crowd and injured severely. It could lead a devastating result. In this paper FFDS system is presented that can minimize the hazard. Along with fire alarm this system announces locations of fire and able to detect severity.

2.5.2 Technique

The forest fire detection system can be divide in three different parts: the fire detector with sensors for temperature and smoke levels, the GSM transmitter which converts the information obtained by sensors into digital data and transmits them through GSM network, and the electrical supply, which should take into account the stand-alone use of this front-end. Although a GSM front-end can be made with discrete components, its integration has many advantages, such as higher microelectronics. The Global Warming Report 2008 mentions forest fire as one of the major cause behind increase in global warming. In recent year 2016 more than 4000 hectares of forest were burnt in the performance at lower cost, size reduction and less power consumption. It is well known, there will be large variations/increase in temperature from the normal temperature whenever forest fire occurs. This can be detected/ monitored continuously by using temperature sensors and in accordance with the simple arrangement of transmitters. This concept is quite reliable and cost-effective in detecting of forest fire's since simple equipment's are arranged in a simple configuration and also GPS is used in this project to get the location of the forest fire. The goal behind the development of this technology was the early detection of forest fires accurately in order to curtail the loss of forests as well as wild life and people as well. The sink then sends the data to a control station, usually far away, via the Internet, Satellite communication, GSM etc.

2.5.3 Drawbacks

- Data frame is limited by size.
- Data transfer speed is low.

2.6 Fire Monitoring System for Fire Detection Using ZigBee and GPRS System

Kiran Kumar.D, Kishore, T.V.Suresh Kumar," Fire Monitoring System for Fire Detection Using ZigBee and GPRS System", IOSR Journal of Electronics and Communication Engineering (IOSR-JECE) Volume 12, Issue 1, Ver. III (Jan.-Feb. 2017).

2.6.1 Introduction

Forest ecosystems are dynamic and complicated. Disturbance to any part of the network affects the balance of relationships and equally on the complete schemes either absolutely or negatively. When global climate change, drought and different conditions have caused occurrences of intense wildfire to extend, which may harm forest badly so once wildfire occurs it takes years to naturally recover. Sometimes wildfire becomes important for forests, however it additionally becomes a threat to them, thus sturdy policies and management are important to prevent wildfire. The best way to prevent such wildfire is to detect fire as early as possible. To detect the fire main three environmental conditions one has to monitor are relative humidity, temperature and wind direction. Two factors which have direct influence on fire are relative humidity and temperature. Temperature is very essential factor in detecting the wildfire as it is a measure requirement in ignition and continuing the combustion process. Humidity is nothing but moisture in the form of water vapour present in the atmosphere. Relative humidity is the percentage ratio of actual water vapour contain to the amount of water vapour that would saturate the atmosphere at the same temperature. Normally fire closure occurs when relative humidity is less than 10%, temperature is in between 89-90F and RH is 15 percent or less, temperature is in between 90-99F and RH is 20 percent or less, temperature is higher than 100F and RH is 25 percent or less Currently for wildfire detection different methods has been deployed such as patrols, satellite monitoring and observations from watch towers. As watch tower method is low cost and easy but it has many drawbacks such as need of trained labors, personal abound as carelessness of labours, absence from the post, limited coverage area. In other hand satellite monitoring is highly costly and comes with drawbacks as it is not effective as the images from satellite sometimes becomes useless due to pixel covered by clouds and also it needs long scanning cycle and resolution of saturated pixel dots of images is low. WSN is solution in between cost and effectiveness. zigbee based sensor nodes in WSN monitors real time temperature and humidity data which effects in wildfire and sends the data to gateway nodes where the collected data is analyzed and change in data is monitor.

2.6.2 Technique

The state machine is made up of three basic state. The transition in state occurs when sudden rise in temperature or relative humidity occurs. The zero state indicates the normal state, in this state the temperature is monitored continuously. This state is in self loop, when sudden rise in temperature occurs machine changes its state from state 0 normal states to the second state. To avoid ambiguity between rise in temperature due to fire and rise in temperature due to other reasons like sunrise or combustion of gases on sun's surface, the machine stays in state. In each state 0, the average of the previous five values of temperature (Tavg) is calculated and which is checked against the new measured value which is t (temperature), if the new measured value is exceeds 3degree Celsius in case of temperature then the change from state0 to state1 occurs. The sensor end point nodes are light in weight and can be mounted on trees, the end points are made with Arduino board interfaced with temperature sensor LM35 and HTM2500 the values are transferred to the gateway nodes via serial communication. For serial communication the ZigBee modules are used which are interfaced with ATmega328 in Arduino board. ZigBee transition is used for 3 meter range with low power of 3.3 v supply. Number of sensor nodes are arranged to cover the entire coverage, these ZigBee will work as routers in the zigbee network. The gateway node is also has Arduino interfaced with zigbee module. Continuous monitoring of these two parameter helps us to detect the occurrence of wildfire. The method has included wireless sensor network to transfer the information. This network has included short range communication via zigbee and long range communication via GPRS. Short range communication has included for data exchange between different area of the forest and to process this data, whereas long term communication has used to send the alert messages. The unique SIM ID in GPRS helps to detect the exact location of the wildfire. This method is less complex and needs low maintenance, and useful in low power application.

2.6.3 Drawbacks

- It is fully not secure.
- Short battery life.
- Speed is very poor.

2.7 Forest Fire Detection Using Optimized Solar Powered Wireless Sensor Networks

Pallavi C. Jamdhade, Ashwini D. Kawate, ShitalS.Lachake," Forest Fire Detection Using Optimized Solar Powered Wireless Sensor Networks", International journal of Advance search in science and engineering, Volume NO.07, Issue NO.02, February 2017.

2.7.1 Introduction

Forests are part of the important and indispensable resources for human survival and social development that protect the balance of the earth ecology. However, because of some uncontrolled anthropogenic activities and abnormal natural conditions, Forest Fires occur frequently. These fires are among the most serious disasters to forest resources and the human environment. In recent years, the frequency of forest fires has increased considerably due to climate changes, human activities and other factors. The prevention and monitoring of Forest Fires has become a global concern in Forest Fire prevention organizations. Currently, Forest Fire prevention methods largely consist of Patrols, Observation from watch towers, Satellite Monitoring and lately Wireless Sensor Networks. Although observation from watch towers is easy and feasible, it has several defects. In the first place, this method requires many financial and material resources and a trained labor force. Second, many problems with fire protection personnel abound, such as carelessness, absence from the post, inability for real-time monitoring and the limited area coverage.

2.7.2 Technique

Microcontrollers have only been with us for a few decades but their impact (direct or indirect) on our lives is profound. Usually these are supposed to be just data processors performing exhaustive numeric operations. Microcontroller is a single chip micro-computer that has everything inbuilt i.e. circuitry of microcontroller has built in RAM, ROM, input output devices, timer, counter, interrupts The 89c series is a low-power, high-performance CMOS 8-bit microcomputer with Flash programmable and erasable read only memory (PEROM). Here We are using ATMELS AT89c/s52 microcontroller. The controller executes instructions as per the clock cycles; this clock is generated using a crystal which is connected to the XTAL1 &

XTAL2 pin of the microcontroller, the two capacitors C1 &C2 are connected between the two XTAL pins &the ground. They are required for the crystal to oscillate. A Power ON reset circuit is connected to the RESET pin of the microcontroller, the controller must be reseted properly whenever is power is turned on, which is done by applying a Vcc to the reset pin & for normal operation of the controller the pin should be pulled low. So an RC (R1, C3) circuit is connected to the RST (9) pin of the microcontroller. Whenever the power is turned ON the Capacitor is fully charged & the RST pin gets 5 v. Then the capacitor slowly discharges through the resistor & is then pulled to ground. Microcontrollers Port 0 does not have an Internal Pull Up resistor so we need external Pull Up resistors on port 0. For which we use 9-Pin SIP resistor which are basically eight resistors with one end common. Mechanical modeling for accessible and inaccessible areas helps in the easy implementation of the Forest Area modules. The system can also be upgraded with low-power elements. In generally, the wireless systems designer has two overriding constraints: it must operate over a certain distance and transfer a certain amount of information within a data rate. The RF modules are very small in dimension and have a wide operating voltage i.e. 3V to 12V.

2.7.3 Drawbacks

- More complex architecture.
- Cost is increases.
- It can't interface high power devices.

2.8 Implementation of Wireless Sensor Network and IOT for Real Time Forest Fire Warning System

S.Varunkumar, P.V Yokeshraj, V.Vignesh," Implementation of Wireless Sensor Network and IOT for Real Time Forest Fire Warning System", International Journal of Engineering and Techniques - Volume 4 Issue 1, Jan – Feb 2018.

2.8.1 Introduction

As we all know, the forest is considered as one of the most important and indispensable resources, the prevention and detection of the forest fire, have been researched

hotly in worldwide Forest Fire Prevention Departments. Forests are the protectors of earth's ecological balance. Unfortunately, the forest fire is usually only observed when it has already spread over a large area, making its control and stoppage arduous and even impossible at times. The result is devastating loss and irreparable damage to the environment and atmosphere (30% of carbon dioxide (CO2) in the atmosphere comes from forest fires), in addition to irreparable damage to the ecology (huge amounts of smoke and carbon dioxide (CO2) in the atmosphere). Among other terrible consequences of forest fires are long-term disastrous effects such as impacts on local weather patterns, global warming, and extinction of rare species of the flora and fauna. Based on the deficiencies of conventional forest fire detection on real time and monitoring accuracy, the wireless sensor network technique for forest fire detection is being implemented here. The problem with forest fires is that the forests are usually remote, abandoned/unmanaged areas filled with trees, dry and parching wood, leaves, and so forth that act as a fuel source. The fire ignition may be caused through human actions like smoking or barbeque parties or by natural reasons such as high temperature in a hot summer day or a broken glass working as a collective lens focusing the sun light on a small spot for a length of time thus leading to fire ignition. Once ignition starts, combustible material may easily fuel to feed the fires central spot which then becomes bigger and wider. The initial stage of ignition is normally referred to as "surface fire" stage. This may then lead to feeding on adjoining trees and the fire flame becomes higher and higher, thus becoming "crown fire." Mostly, at this stage, the fire becomes uncontrollable and damage to the landscape may become excessive and could last for a very long time depending on prevailing weather conditions and the terrain.

2.8.2 Technique

The real time transmission and reception of parameters such as humidity, temperature, air quality, and location are obtained. The Raspberry Pi is more efficient than its other counterparts in multiprocessing of data with minimum expenditure of power. The Wireless sensor node network ensures long distance transmission of data from inside dense forest to the receiver even if it has poor network coverage. The forest is scattered with multiple zig bee node points and they transmit it to a central zig bee system and each central zig bee transmits its data individually to the receiver end which receives all sensor data from each node point in of the

forest The live monitoring and condition based picture capturing method ensures an additional warning system that forest fire occurred. And is programmed to be in sleep mode when not triggered to save power. SMTP protocol and SMS are an efficient method to send an early warning whenever a forest fire is detected. Through this way an early warning intimation when a forest fire occurs reaches the monitoring station and immediate actions on extinguishing the fire are taken.

2.8.3 Drawbacks

- Low short range.
- High maintenance.
- Low network stability**.**

2.9 Iot Enabled Forest Fire Detection and Altering the Authorities

T. Sai Kumar, P. Sriramya," Iot Enabled Forest Fire Detection and Altering the Authorities", International Journal of Recent Technology and Engineering (IJRTE) Volume-7, Issue-6S4, April 2019.

2.9.1 Introduction

In the present arena, wildlife and forest departments are facing the problem of movement of animals from forest area to residential area. The number of trees has reduced drastically from the forest that creates an unhealthy environment for animals to survive in the forest. It has been found in a survey that 80% losses are caused due to fire. This could have been avoided if the fire was detected in the early stages. This project proposes a system for tracking and alarming for the protection of trees against forest fires. Nowadays IOT (Internet of Things) devices and sensors allow the monitoring of different environmental variables, such as temperature, humidity, moisture etc. Arduino platform based IOT enabled fire detector and monitoring system is the solution to this problem. In this project we have built fire detector using Arduino UNO which is interfaced with a temperature sensor, a smoke sensor and a buzzer. In order to implement this project, we will be using GSM which is used to provide the final

SMS to the user through the given number in the simulation program, Temperature sensor which is used to denote the temperature High and Low that will be displayed in the LCD Display, Flame sensor which is used to denote the flame ranges and if it is high the forest fire will be detected in the LCD display and if it is low forest fire won't be detected. Whenever a fire occurs, the system automatically senses and alerts the user by sending an alert to an app installed on user's android mobile or webpage accessible through the internet.

2.9.2 Technique

Arduino/Genuino Uno is a microcontroller board subject to the UNO, which we are using. It has 14 induced data/yield pins in which 6 can be used as PWM yields, 6 fundamental data sources, a 16 MegaHz quartz gainful stone, a USB affiliation, a power jack, an ICSP header and a reset catch which used for resetting input data. You can gauge temperature frequently than a utilizing an indoor regulator. This is a remote modem that works with an its remote framework. It continues like a dial-up GSM modem. The main difference between the dial-up modem sends and gets the data through a fixed telephone line but, which a remote modem sends and gets the data through radio waves. Appealing transducers contain an alluring circuit involving an iron focus with damage twist and a weight plate, an unending magnet and a vibrating stomach with a portable iron piece. Ringers like the TMB-course of action are alluring fit for being heard banner devices with natural faltering circuits. Transistors, resistors, diodes and other little devices go about as circuit contraptions for driving sound generators. IOT based forest fire detection was implemented using the Arduino. So when the temperature is increased it will display on the LCD and also gives message to authorities by using the registered mobile number. Same process is implemented for the fire detection, when the flame gets increased the buzzer will get activated and intimation will be conveyed to the authorities.

2.9.3 Drawbacks

- It don't get to the know about micro controller inside the Arduino deeply.
- Arduino IDE get limited library.
- Important factor is cost.

2.10 Fire Alarm System Using IOT

Angeline.R, Aditya.S, Abhishek Narayanan," Fire Alarm System Using IOT", International Journal of Innovative Technology and Exploring Engineering (IJITEE) Volume-8, Issue-6S3, April 2019.

2.10.1 Introduction

Forests generate water supplies, biodiversity, pharmaceuticals, recycled nutrients for agriculture and flood prevention, and are central to the transition towards a Green Economy in the context of sustainable development and poverty eradication. Recent studies into the extent of illegal logging estimate that illegal logging accounts for 50-90 per cent of the volume of all forestry in key producer tropical countries and 15-30 per cent globally. At home and abroad there are forest fire preventions such as artificial way of looking, forest aircraft, Fire-Watch forest fire automatic warning systems and satellite circuit monitoring system,. Not only does it help in improving the efficiency of a device\ but also has economic benefits. Iot is just another way to make everyday life easier for humans by developing smart devices. The market value for IoT devices is also set to increase to $7.1 million by the year 2020. Iot involves connecting objects beyond the range of standard devices which are used for everyday purposes. In this paper we have developed an IoT based fire alarm with additional safety and verification methods. The devices uses a wide variety of sensors- PIR sensor, to detect the exact location of the origin of fire. Gas sensor, it detects the presence of any flammable gas like CO2. Temperature sensor, detects of there is any unusual change in the room temperature. The connectivity and compilation of data is done by using a Raspberry Pi 3. As soon as the sensors detect some unusual activity, the web camera attached to the device takes a picture of the surrounding and sends it to the watchman and the nearby fire stations. The watchman has a grace period of 120 seconds to confirm the fire and its validity. Upon his verification the fire Marshalls arrive at the scene to put out the fire. If the message is unanswered by the watchman for 120 seconds the device sends out a red alert to the fire station requesting their immediate arrival.

2.10.2 Technique

Fires cause serious damage and disrupts daily life in a devastating manner. Hence preventing them or reducing their effects is a top priority. Though there are many systems that have been created to tackle this problem, false alarms is a challenge that is yet to be avoided. In our model, the place to be monitored is under constant surveillance by a closed circuit television. At tactical points, a number of sensors are placed. The sensor include pir sensor, temperature sensor, heat sensor and gas sensor. Each sensor plays a vital role in detecting a fire if it occurs. On top of these sensors, the footage from the camera is also used to detect the fire through image processing. The main advantage of this system is that it has a very high accuracy. If the fire has been detected a mail is sent to the security and the nearest fire department with an attachment of the photo. The architecture diagram is almost self-explanatory. The sensors and the camera act as input devices that gives input data to the raspberry pi which then processes the information and deduces through the unique algorithm whether there is a fire or not. The buzzer and spikler are close vicinity warning and countermeasure system while the wifi is used to send a message to the security guard and the nearest fire department.

2.10.3 Drawbacks

- It does not replace your computer.
- Processor is not so fast.
- Time consuming to download and the software.

Table 2.1 Summary of literature survey

Paper Title	Technique used	drawbacks
Forest Fire Detection and Alerting System	The powerful feature of wireless sensor networks as a potential solution to the challenge of early detection of forest fires.	➢ Short range ➢ Low data speed
Forest Fire Detection using Wireless Sensor	➢ Wireless sensors for forest fire detection. ➢ Alert is send using GSM module.	➢ It is not fully secure. ➢ Short battery life.
Design And Development Of Automatic Fire Detection Using Sms And Voice Alert System	➢ Sending short message (SMS) via GSM network and voice alerting system. ➢ Fire extinguisher during the fire accidents.	➢ GPS location not in proper because of low signal strength. ➢ Cannot interface high power directly.
Forest Fire Detection System	The fire hazard FFDS notifies the control room and others by text messages.	➢ Data frame is limited by size. ➢ Data transfer speed is low.
Forest Fire Detection Using Optimized Solar Powered Wireless Sensor Networks	The technologies of MODIS and Basic Wireless Sensor Network - based Forest Fire Detection Systems.	➢ Cost is increases. ➢ It can't interface high power devices.

Fire Monitoring System for Fire Detection Using ZigBee and GPRS System	The present methodology based on ZigBee and GPRS wireless sensor network.	➢ Using ZigBee data transfer not possible in long distance
Implementation of Wireless Sensor Network and IOT for Real Time Forest Fire Warning System	➢ The real time monitoring system. ZigBee module and Gps location	➢ High maintenance. Low network stability
Forest-Fires Surveillance System Based On Wireless Sensor Network	➢ Current surveillance systems utilize a camera, an infrared sensor system and a satellite system	➢ Camera resolution or blur may occur so accuracy is not good. ➢ Low data speed.
IOT Enabled Forest Fire Detection and Altering the Authorities	➢ Arduino platform based IOT technology. ➢ Alerts the user by sending an app installed on user's android mobile.	➢ It don't get to the know about micro controller inside the Arduino deeply
Fire Alarm System Using IOT	➢ The Raspberry Pi and real time sensor with IOT technology.	➢ More expensive components. ➢ Processor is not so fast.

CHAPTER-3

THEORETICAL BACKGROUND

3.1 Exciting Method

The paper depicts the necessity and an efficient solution for fire safety. Internet of Things was the main concept used and the project mainly builds on the techniques which are already presents and also it has overcome many obstacles present in the previous systems. But still there are few tweaks and remodeling required to get a more efficient and working model. The time taken for process is to be reduced for practical use.

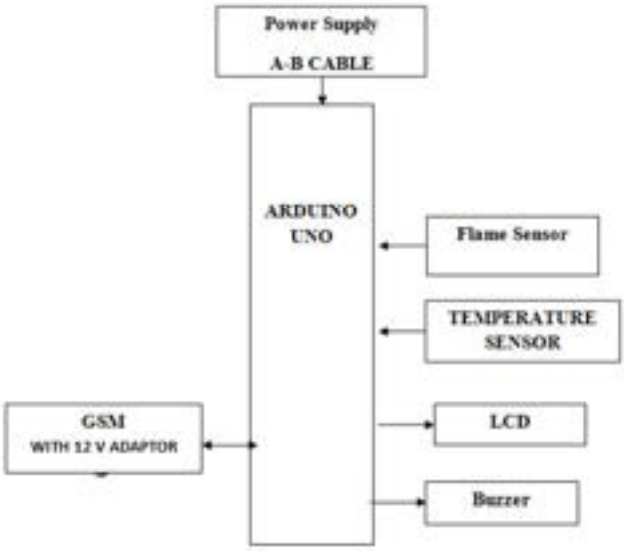

Fig 3.1 Exciting Block Diagram

Fires cause serious damage and disrupts daily life in a devastating manner. Hence preventing them or reducing their effects is a top priority. Though there are many systems that have been created to tackle this problem, false alarms is a challenge that is yet to be avoided.

In our model, the place to be monitored is under constant surveillance by a closed circuit television. At tactical points, a number of sensors are placed. The sensor include flame sensor, temperature sensor. Each sensor plays a vital role in detecting a fire if it occurs. On top of these sensors, the footage from the camera is also used to detect the fire through image processing. The main advantage of this system is that it has a very high accuracy.

3.2 Proposed System

The proposed system is cloud based forest fire alert system using IOT technology. The most common hazard in forest fire Accident are themselves destroy the forest and great threat for wildlife and peoples. The number of trees has reduced drastically so the forest are creates an unhealthy environment for animals to survive in the forest. Forest covers 31% of the world and 21% of the India. It has found in a survey that 80% of losses are caused due to fire. This project of a system fire was detected early stages. It was tracking and alarming for protection of trees against forest fire. Now IOT (Internet of things) devices and cloud based to forest fire alerting system. If cloud can used to storing the information of data to monitoring the different environmental variables such as temperature, smoke, moisture of the forest. So finally to prevent the fire to spread over a huge area and precaution the forest. In the advancing world, it is very crucial to protect our environment. In wild animals are most affected and die also known for forest fire. If forest trees also burned to affect atmosphere, environment. This fire made naturally and man-made. So this project need to prevent and pre-cautions from forest fire. In order to achieve the best fire detection result with faster time to detect the temperature variation. When temperature sensor used to measure the temperature variation. Smoke sensor is a device that dense smoke, typically as an indicator of fire. Arduino at mega 328p used to control and monitor the activities. Cloud is a storage purpose to use him. Because each and every second to monitoring the environment condition data can be stored. IOT Device to interface with Arduino and cloud.so finally fix the monitoring system done in nearby forest office station. The detail about the system is connected with a computer system monitored by the officer.

- Cloud computing.

3.2.1 Cloud computing

Cloud computing is the on-demand availability pf computer system resources, especially data storage and computing power, without direct active management by the user. The term is generally used to describe data centers available to many users over the internet. Cloud computing services provide information technology (IT) as a service over the internet or dedicated network, and payment based in usage. Cloud computing services range from full applications and development platforms, to servers, storage, data base, networking, software, analytics, intelligence, and virtual desktops over the internet to offer faster innovation, flexible resource, and economics of scale.

3.3 Block Diagram

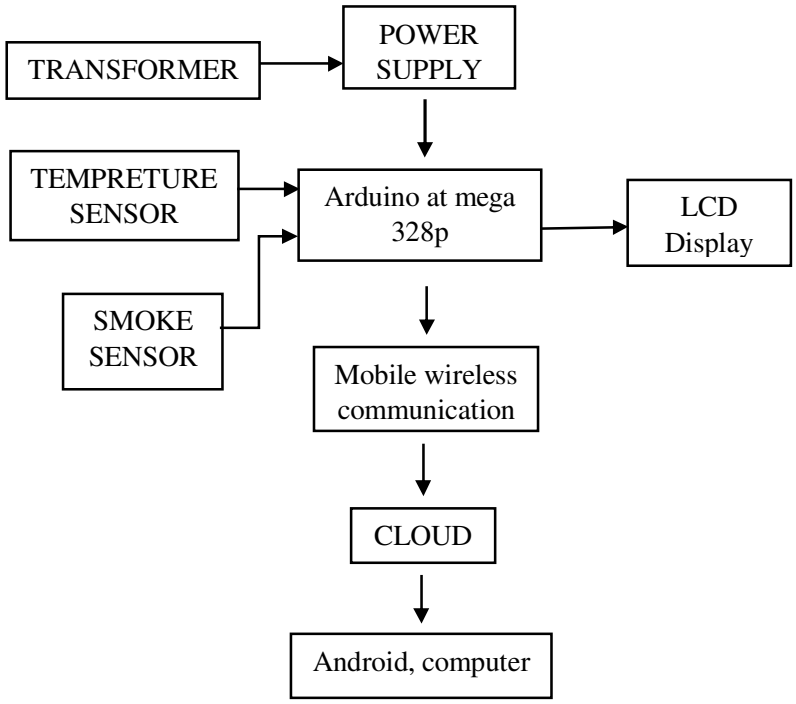

Fig 3.2 Block Diagram of Proposed System

3.3.1 Arduino atmega 328p

ATMEGA328P is high performance, low power controller from Microchip. ATMEGA328P is an 8-bit microcontroller based on AVR RISC architecture. It is the most popular of all AVR controllers as it is used in ARDUINO boards. ATMEGA328 is used similar to any other controller. All there to do is programming. Controller simply executes the program provided by us at any instant. Without programming controller simply stays put without doing anything. As said, first we need to program the controller and that is done by writing the appropriate program file in the ATMEGA328P FLASH memory. After dumping this program code, the controller executes this code and provides appropriate response.

Fig 3.3 Atmega 328p Microcontroller

3.3.2 Temperature Sensor

LM35 is a temperature sensor that outputs an analog signal which proportional to the instantaneous temperature. The output voltage can easily be interpreted to obtain a temperature reading in Celsius. The advantage of LM35 over thermistor is it does not require any external calibration. The coating also protects it from self-heating. Low cost and greater accuracy. It is a small and cheap IC which can be used to measure temperature anywhere between -55°C to 150°C. It can easily be interfaced with any Microcontroller that has ADC function or any development platform like Arduino. Power the IC by applying a regulated voltage like +5V (VS) to the input pin and connected the ground pin to the ground of the circuit.

Fig 3.4 Temperature Sensor of LM35

3.3.3 Smoke Sensor MQ-2

The MQ-2 is a flammable gas and smoke sensor detects the concentrations of combustible gas in the air and outputs its reading as an analog voltage.The sensor can measure concentrations of flammable gas of 300 to 10,000 ppm.The MQ-2 gas sensor is sensitive to LPG, i-butane, propane, methane, alcohol, Hydrogen and smoke. They are used in gas leakage detecting equipment's in family and industry and in portable gas detector.

Fig 3.5 smoke sensor MQ-2

3.3.4 Bluetooth

The Bluetooth module HC-05 is a MASTER/SLAVE module. By default the factory setting is SLAVE. The Role of the module (Master or Slave) can be configured only by

AT COMMANDS. The slave modules cannot initiate a connection to another Bluetooth device, but can accept connections. Master module can initiate a connection to other devices.

Fig 3.6 Bluetooth HC-05

The user can use it simply for a serial port replacement to establish connection between MCU and GPS, PC to your embedded project, etc.

3.3.5 LCD Display

16×2 LCD is named so because; it has 16 Columns and 2 Rows. There are a lot of combinations available like, 8×1, 8×2, 10×2, 16×1, etc. But the most used one is the 16*2 LCD, hence we are using it here. These black circles consist of an interface IC and its associated components to help us use this LCD with the MCU. Because our LCD is a 16*2 Dot matrix LCD and so it will have (16*2=32) 32 characters in total and each character will be made of 5*8 Pixel Dots.

Fig 3.7 LCD Display

CHAPTER 4

SYSTEM SPECIFICATION

4.1 Hardware Requirements

- Arduino atmega 328p
- Temperature sensor
- Smoke sensor
- Bluetooth
- LCD Display
- Transformer
- Cloud

4.2 Software Requirements

- Windows 7
- Visual studio
- Embedded C

4.1 Hardware Explanation

4.1.1 Arduino atmega 328p

Arduino is an open source computer hardware and software company, project and user community that designs and manufactures single- board micro controller micro controller kits for building digital devices and interactive objects that can sense and control object in the physical and digital world. Arduino board designs use a variety of microprocessors and controllers. The boards are equipped with sets of digital and analog input/output (I/O) pins that may be interfaced to various expansion boards or bread boards.

Arduino Uno is a microcontroller board based on the Atmega328p.

Fig 4.1 Arduino At mega 328p

It has 14 digital input/output pins (of which 6 can be used as PWM outputs), 6 analog inputs, a 16 MHz quartz crystal, a USB connection, a power jack, an ICSP header and reset button. It contains everything needed to support the micro controller, simply connect it to a computer with a USB cable or power it with a AC-to-DC adapter or battery to get started. You can tinker with your UNO without worrying too much about doing somethings wrong, worst case scenario you can replace the chip for a few dollars and starts over again. The Uno board and version 1.0 of Arduino software (IDE) were the reference versions of Arduino, now evolved to newer release the uno board is the first in a series of USB Arduino boards, and the reference model for the Arduino platform.

4.1.1.1 Pin diagram

Arduino atmega 328p is a 28 pin chip as shown in above. Many pins of the chip here have more than one function. We will describe functions of each pin in below.

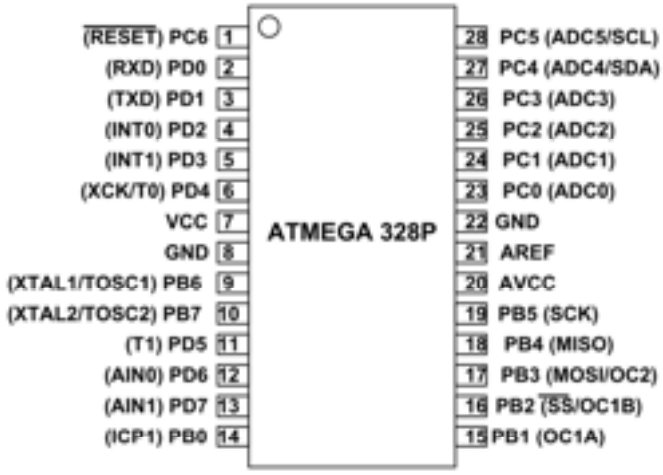

Fig 4.2 Pin diagram of ATMEGA 328p

In pin no.1 name is PC6 (RESET) pin by default is used as RESET pin. PC6 can only be used as I/O pin when RSTDISBL Fuse is Programmed. Pin No.2 is PD0 (RXD) is (Data input pin for USART) is used serial communication interface. Pin no.3 PD1 (TXD) is (Data output pin for USART) is used serial communication interface with INT2 (External interrupt 2 input).Pin no.4 is PD2 (INTO) used external interrupt source 0. Pin no.5 is PD3 (INT1/OC2B) External interrupt source1wiith OC2B (PWM – Timer? Counter2 output compare Match B output).pin no.6 PD4 (XCK/T0) T0 (Timer0 External counter input) and XCK (USART external clock I/O). Pin no.7 is Denotes VCC is connected to positive Voltage. Pin no.8 GND is connected to Ground.

Pin no.9 is PB6 (XTAL1/TOSC1) is XTAL1 (chip clock oscillator pin 1 or external clock input) and TOSC1 (timer oscillator pin 1).pin no.10 is P7 (XTAL2/TOSC2) XTAL2 (chip clock oscillator pin 2) and TOSC2 (timer oscillator 2). Pin no.11 is PD5 (T1/OC0B) is T1 (timer1 external counter input) and OC0B (PWM- timer/counter0 output compare match B output). Pin no.12 PD6 (AIN0/OC0A) is AIN0 (Analog comparator positive I/P) and OC0A (PWM-timer/counter0 output compare Match A output). Pin no.13 is PD7 (ALN1) is ALN1 (analog comparator negative I/P). Pin no.14 PB0 (ICP1/CLK0) is denotes ICP1 (timer/counter 1 input capture pin) and CLK0 (divided system clock. The divided system

clock can be output on the PB0 pin). Pin no.15 is PB1 (OC1A) is OC1A (timer/counter1 output compare match A output). Pin no.16 PB2 (SS/OC1B) is SS (SPL slave select input). This pin is low when controller acts as slave. And OC1B (timer/counter1 output compare match B output).

Pin no.17 PC4 (ADC4/SDA) is ADC4 (ADC input channel 4) and SDA (two-wire serial bud data input/output line). Pin no.18 PB4 (MISO) is MISO (master input slave output). When controller acts as slave, the data is sent to master by this controller through this pin. Pin no.19 is PB5 (SCK) is SCK (SPI bus serial clock). This is the clock shared between this controller and other system for accurate data transfer. Pin no.20 is AVCC is power for internal ADC converter. Pin no.21 is AREF is analog reference pin for ADC. Pin no 22 is GND is denoted as ground. Pin no.23 is PC0 (ADCO) ADC0 (ADC input channel 0). Pin no.24 is PC1 (ADC1) is ADC1 (ADC input channel 1) to Pin no.28 PC5 (ADC5/SCL) is denotes ADC5 (ADC input channel 5) and SCL (two-wire serial bus clock line).

4.1.1.2 Architecture of Atmega 328p

Here architecture is of Arduino or precisely the IC of Arduino (atmega 328p). The atmega 328p is a low power CMOS 8-bit micro controller based on the AVR enhanced RISC (reduced instruction set computer) architecture.

In order to maximize performance and parallelism, the AVR uses Harvard architecture- with separate memories and buses for program and data. Instruction in the program memory are executed with a single level of pipelining. The clock is controlled by an external 16 MHZ crystal oscillator.

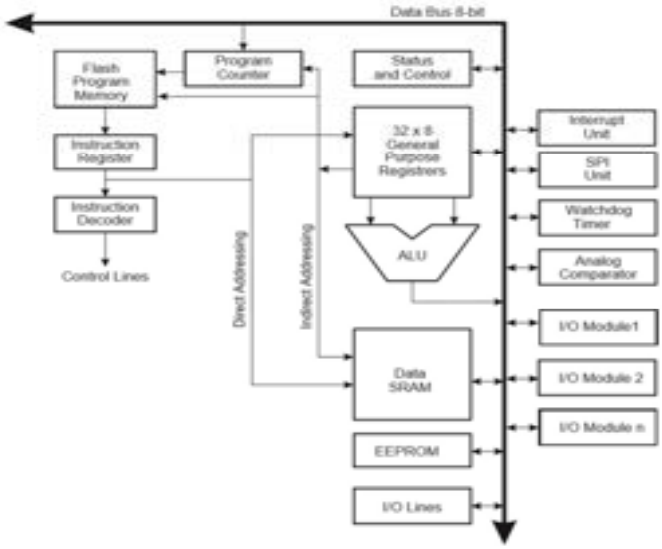

Fig 4.3 Architecture of ATMEGA 328p

The basic working of CPU of Atmega 328p

1. The data is uploaded in serial via the port (being upload from the computer's Arduino IDE). The data is decoded and then the instructions are sent to instruction register and it. Decodes the instructions on the same clock pulse.
2. On the next clock pulse the next pulse the next set of instructions are loaded in instruction register.
3. In general purpose register the registers are of 8-bit but there are 3 16- bit register also.
   a. **8-bit** registers are used to store data for normal calculations and results.
   b. **16-bit** registers are used to store data of timer counter in 2 different register. Eg. X-low & X-high. They are fast, and are used to store specific hardware functions.
4. **EEPROM** stores data permanently even if the power is cut out. Programming inside a EEPROM is slow.
5. **Interrupt unit** check whether there is an interrupt for the execution of instruction to be executed in ISR (interrupt service Routine).
6. **Serial peripheral interface (SPI)** is an interface bus commonly used to send data between micro controllers and small peripherals such as camera, Display, SD cards, etc. it uses

separate clock and data lines, along with a select line to choose the device you wish to talk to.

7. **Watchdog** timer is used to detect and recover from MCU malfunctioning.
8. **Analog comparator** compares the input values on the positive and negative pin, when the value of positive pin is higher the output is set.
9. **Status and control** is used to control the flow of execution of commands by checking other blocks inside the CPU at regular intervals.
10. **ALU (Arithmetic and logic unit)** the high performance AVR ALU operates in direct connection with all the 32 general purpose working registers. Within a single clock cycle, arithmetic operations b/w general purpose register are executed. The ALU operations are divided into 3 main categories- arithmetic, logical, and bit- function.
11. **I/O Pins** the digital inputs and outputs (digital I/O) on the Arduino are what allow you to connect the Arduino sensors, actuators, and other ICs. Learning how to use them will allow you to use the Arduino to do some really useful things, lightings indicators, and controlling relay outputs.
12. **Automatic (software) Reset** rather than requiring a physical press of the reset button before an upload, the Arduino is designed in a way that allows it to be reset by software running on a connected computer. The Arduino software (IDE) uses this capability to allow you to upload button in the Arduino environment.

4.1.1.3 Specification of At mega 328p

Operating voltage	5V
Recommended input voltage	7-12V
Input voltage limits	6-20V
CPU	8-bit
Number of pins	28

Analog input pins	14(of which 6 provide PWM output)
Digital I/O pins	6
DC current per I/O pin	40mA
Flash Memory	32KB(atmega328) of which 0.5 KB used by boot loader
Clock speed	16 MHZ
EEPROM	1 Kbytes EEPROM
RAM	2kbytes for 1MHz
Operating temperature	-40^0c to $+105^0$c(+105 being absolute maximum, -40 being absolute minimum)

4.1.2 Temperature sensor of LM35

The temperature sensor of LM35 is used to this project. LM35 is a temperature sensor that outputs an analog signal which proportional to the instantaneous temperature. The output voltage can easily be interpreted to obtain a temperature reading in Celsius. The advantage of LM35 over thermistor is it does not require any external calibration. The coating also protects it from self-heating. Low cost and greater accuracy make it popular among hobbyists, DIY circuit makers, and students. Many low- end products take advantage of low, greater accuracy and used LM35 in their products. It's approximately 15+ years to its first release but the sensor is still surviving and is used in any products.

Fig 4.4 Temperature sensor of LM35

LM35 can measure from -55 degrees centigrade to 150-degree centigrade. The accuracy level is very high if operated at optimal temperature and humidity levels. The conversion of the output voltage to centigrade is also easy and straight forward. The input to LM35 can be from +4 volts to 30 volts. It consumes about 60 microamperes of current. LM35 has many family members a few names areLM35C, LM35CA, LM35D, LM135, LM235, and LM355. All LM35 family members work on the same principles but temperature measuring capacity varies and also they are available in many package (SOIC, TO-220, TO-92, TO).

- Linear +10-mv/^{0}c scale factor

In order to understand the working principle of LM35 temperature sensor we have to understand the linear scale factor. In the features of LM35 it is given to be +10 mills volt per degree centigrade. It means that with increase in output of 10 mills volt by the sensor vout pin the temperature value increases by one. For example, if the sensor is outputting 100 mills volt at vout pin the temperature in centigrade will be 10-degree centigrade. The same goes for the negative temperature reading. If the sensor is outputting -100mills volt the temperature will be -10 degrees Celsius.

4.1.2.1 Circuit Diagram of LM35

LM35 can be used in two circuit configuration. Both yield different results. In the first co0nfiguration, you can only measure the positive temperature from 2 degrees Celsius to 150 degrees Celsius. In this first configuration, we simply power lm35 and connect the output directly to analog to digital converters. In the second configuration, we can utilize all the sensor

resources and can measure the full range temperature from -55 degree centigrade to 150 degree centigrade. This configuration is a little complex but yield high results. We have to connect an external resister, in this case, to switch the level of negative voltage upwards. The external resister value can be calculated from the formula given below the configuration circuit. The second configuration circuit can be made in various ways. To see about the second configuration circuits visit the LM35 datasheet by Texas instruments enlists the circuit with clear component value.

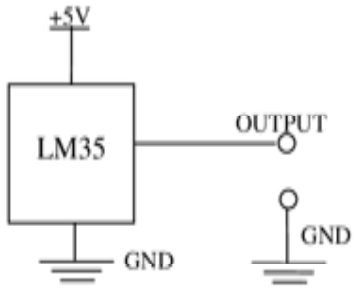

Fig 4.5 Circuit diagram for LM35

Although the first configuration did not need a resister at the output side, I recommended connecting an 80k to 100k resister between vout and ground pin. When I performed several experiments I noticed that the readings some time fluctuate and the vout pin floats. So a resister between ground tights the vout pin low and prevents them from floating.

PARAMETER	VALUE
Accuracy at 25^0c	+/- 0.5 ^{0}c
Accuracy from -55^0c to 150^0c	+/- 1^0c
Temperature slope	10 mv/^{0}c

The accuracy parameters for both configurations are different. The average accuracy level is +-1 degree Celsius for both configurations. But the accuracy level decreases for temperature between 2-degree to 25 degree centigrade. Now that we have discussed the LM35 temperature pin out, structure, linear scale factor and accuracy level it's time to list down the steps on how to measure temperature using LM35 temperature sensor.

4.1.2.2 Working principle of LM35

In principle, the sensor will perform sensing when the temperature changes every 1 ºC temperature will show a voltage of 10 mV. In placing the LM35 can be affixed with adhesive or can be cemented on the surface but the temperature will be slightly reduced by about 0.01 ºC being absorbed in the surface temperature. In this way the expected difference between the air temperature and the surface temperature can be detected by a sensor LM35 same temperature as the surrounding, if the surrounding air temperature is much higher or much lower than the surface temperature, the LM35 is the surface temperature and the temperature of the surrounding air.

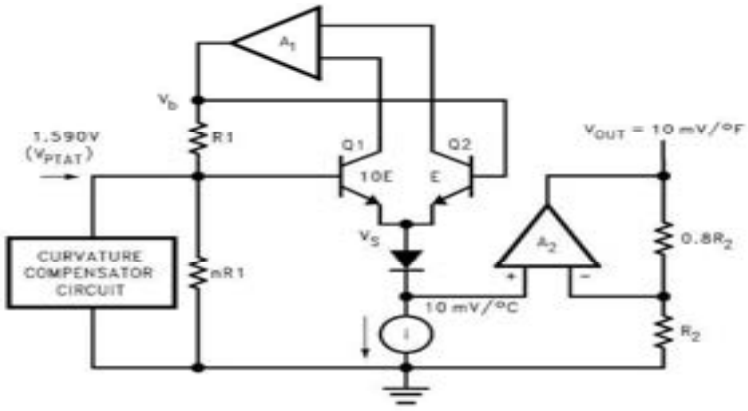

Fig 4.6 Working principle of LM35

The long distance necessary liaison which is not affected by interference from the outside, so use the cable sheath is earthed so that it can act as an antenna receiver and deviation therein, can also act as a rectifier which corrects in such cases, using the method of

bypass capacitors from Vin to be earthed. So we can conclude LM35 sensor working principle as follows.

- The ambient temperature in the detection using the IC part temperature sensitive.
- The ambient temperature is converted into electrical voltage by a circuit in the IC, where the Temperature change is proportional to the output voltage changes.
- In the series LM35

Vout=10 mV/^{0}c

Every change of 1 $^{\circ}$ C would produce a change in output voltage of 10mV s ebesar. Vout is a scalable sensor output voltage linearly with the measured temperature, which is 10 millivolts per 1 degree Celsius. So if Vout = 530mV, then the measured temperature is 53 degrees Celsius. If Vout = 320mV, then the measured temperature is 32 degrees Celsius. The output voltage can be directly fed as input to the signal conditioning circuit such as the operational amplifier circuit and filter circuits, or other circuits such as voltage comparator circuit.

The basic circuit enough to merely experiment or for applications that do not require a perfect measurement accuracy. But not for a real application. Evident from the experiments that I have done, sensor output voltage is not yet stable. At the temperature conditions are relatively similar, if my supply voltage fluctuates (I raise or lower), then Vout also changes. Indeed, the logic of this seems true, but for the instrumentation it is not allowed. Compared with the level of precision, the degree of accuracy of measuring instruments more prominent since the measuring instrument should be used as a benchmark for its users. If the value is changeable relative to the condition that there is no change, then the measuring tool so it cannot be used.

4.1.2.3 Steps to calculate temperature

- Build circuit.
- Power LM35 Vcc to +5-20 volts and Ground.

- Connect Vout to analog to digital converter input.
- Sample the readings, Vout voltage.
- Convert the voltage to temperature.

Centigrade temperature = voltage read by ADC/ 10 mV (mills volt)

I divided by 10 mV because linear scale factor is for is 10 mV. Following the above steps and tutorial, you can easily interface LM35 temperature sensor with any microcontroller that has a built in analog to digital converter pins. Almost all the micro controllers today have built in ADC.

4.1.2.4 LM35 temperature of features

- Calibrated directly in Celsius (centigrade).
- Linear +10 mV/^{0}c scale factor.
- 0.5^{0}c ensured accuracy (at 25^{0}c).
- Rated for full -55^{0}c to 150^{0}c range.
- Suitable for remote applications.
- Operates from 4V to 30V.
- Less than 60- micro A current drain.
- Low self- heating, 0.08^{0}c in still Air.
- Non-linearity only +/- 1/4^{0}c typical.
- Low- impedance output, 0.1 ohm for 1-mA load.

4.1.2.5 Specification of LM35

Communication protocol	Analog Output
Power supply	-2 to 35V
Temperature Range	-55 to 150^{0}c

Accuracy	+/-0.5^{0}c (at 25^{0}c)
Output voltage	-1 to 6V
Output current	10mA

4.1.3 Smoke Sensor of MQ-2

The MQ-2 Smoke LPG Butane Hydrogen Gas Sensor Detector Module is useful for gas leakage detection (home and industry). It is suitable for detecting H2, LPG, CH4, CO, Alcohol, Smoke or Propane. Due to its high sensitivity and fast response time, measurement can be taken as soon as possible. The sensitivity of the sensor can be adjusted by the potentiometer. MQ-2 gas sensor using gas sensitive material is to be clean air in the lower conductivity of Tin oxide (SnO2).

Fig 4.7 Smoke Sensor MQ-2

When the sensor when flammable gases are present in the environment in which the conductivity of the sensor with an increasing concentration of combustible gas in the air increases. Use a simple circuit to convert the changes in conductivity and output signal that corresponds to the concentration of the gas. Using an MQ sensor it detects a gas is very easy. You can either use the digital pin or the analog pin to accomplish this. Simply power the module with 5V and you should notice the power LED on the module to glow and when no gas it detected the output LED will remain turned off meaning the digital output pin will be 0V. Remember that these sensors have to be kept on for pre-heating time (mentioned in features

above) before you can actually work with it. Now, introduce the sensor to the gas you want to detect and you should see the output LED to go high along with the digital pin, if not use the potentiometer until the output gets high. Now every time your sensor gets introduced to this gas at this particular concentration the digital pin will go high (5V) else will remain low (0V).

MQ2 gas sensor can be used to detect the presence of LPG, Propane and Hydrogen, also could be used to detect Methane and other combustible steam, it is with low cost and suitable for different application. Sensor is sensitive to flammable gas and smoke. Smoke sensor is given 5 volt to power it. Smoke sensor indicate smoke by the voltage that it outputs .More smoke more output. A potentiometer is provided to adjust the sensitivity. Sn02 is the sensor used which is of low conductivity when the air is clean. But when smoke exist, an analog output is produced based on the concentration of smoke. The circuit has a heater. Power is given to heater by VCC and GND from power supply.

MQ-2 gas sensor higher sensitivity to liquefied petroleum gas, propane, hydrogen, detection of gas and other combustible vapors are ideal. This sensor can detect a variety of flammable gas, is a low-cost sensor for many applications.

4.1.3.1 Pin diagram of gas sensor MQ-2

In pin number 1 is represents Vcc is pin powers the module, typically the operating voltage is +5V. Pin number 2 is Ground is Used to connect the module to system ground. If pin number 3 is Digital Out is you can also use this sensor to get digital output from this pin, by setting a threshold value using the potentiometer. And the pin number 4 is consists, Analog out is pin outputs 0-5V analog voltage based on the intensity of the gas.

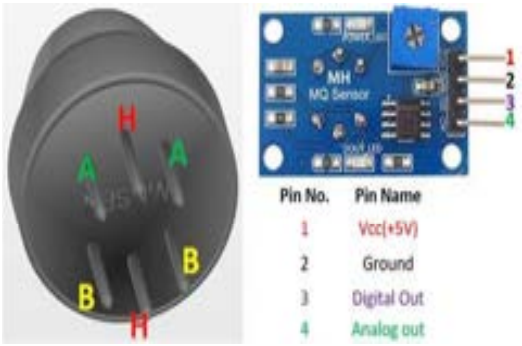

Fig 4.8 Pin diagram of MQ-2

In A-Pins is the A pins and B pins are interchangeable. These pins will be tied to the Supply voltage, B-pin is the A pins and B pins are interchangeable. One pin will act as output while the other will be pulled to ground. H- Pin is Out of the two H pins, one pin is connected to supply and the other to ground.

4.1.3.2 Working principle of smoke sensor MQ-2

This sensor contains a sensing element, mainly aluminum-oxide based ceramic, coated with Tin dioxide, enclosed in a stainless steel mesh. Sensing element has six connecting legs attached to it. Two leads are responsible for heating the sensing element, the other four are used for output signals.

Sensors are the electronic devices used for interaction with the outer environment. There are various types of sensor available that can detect light, noise, smoke, proximity etc. With the advent in technology, these are available as both analog and digital forms. Besides forming a communication with the outer environment, sensors are also a crucial part of safety systems. Fire sensors are used to detect the fire and take appropriate precautions on time. For smooth functioning of control systems and sensitive electronics, humidity sensors are used for maintaining humidity in the unit. One of such sensor used in safety systems to detect harmful gases is MQ2 Gas sensor.

Fig 4.9 Working of MQ-2 sensor

Oxygen gets adsorbed on the surface of sensing material when it is heated in air at high temperature. Then donor electrons present in tin oxide are attracted towards this oxygen, thus preventing the current flow. Now current can flow through the sensor, which generated analog voltage values.

These sensors are used to detect the presence of gases in the air such as methane, butane, LPG and smoke but they are unable to distinguish between gases. Thus, they cannot tell which gas it is. Module version of this sensor can be used without interfacing to any microcontroller and is useful when detecting only one particular gas. This sensor is also used for Air quality monitoring, Gas leak alarm and for maintaining environmental standards in hospitals. In industries, these are used to detect the leakage of harmful gases. These voltage values are measured to know the concentration of gas. Voltage values are higher when the concentration of gas is high

4.1.3.3 Features of smoke sensor MQ-2

1. Good sensitivity to Combustible gas in a wide range
2. High sensitivity to LPG, Propane, and Hydrogen
3. Long life and low cost

4. Simple drive circuit
5. Can be used as a Digital or analog sensor
6. The Sensitivity of Digital pin can be varied using the potentiometer
7. Can be used to Measure or detect LPG, Alcohol, Propane, Hydrogen, CO and even methane.

4.1.3.4 Specification of Smoke Sensor MQ-2

Operating Voltage	+5V
Analog Output Voltage	0V to 5V
Digital output Voltage	0V to 5V (TTL Logic)
Heating consumption	0.5 to 800mW
Equivalent sensors	MQ-6,AQ-2,MQ-306A
Concentration	200 to 1000ppm

4.1.4 Bluetooth HC-05

HC-05 is a Bluetooth module which is designed for wireless communication. This module can be used in a master or slave configuration.

The **HC-05** has two operating modes, one is the Data mode in which it can send and receive data from other Bluetooth devices and the other is the AT Command mode where the default device settings can be changed. We can operate the device in either of these two

modes by using the key pin as explained in the pin description. It is very easy to pair the HC-05 module with microcontrollers because it operates using the Serial Port Protocol (SPP). Simply power the module with +5V and connect the Rx pin of the module to the TX of MCU and TX pin of module to Rx of MCU as shown in the figure below

Fig 4.10 Bluetooth HC-05

HC - 05 module is an easy to use **Bluetooth SPP (Serial Port Protocol) module**, designed for transparent wireless serial connection setup. The HC-05 Bluetooth Module can be used in a Master or Slave configuration, making it a great solution for wireless communication. This serial port Bluetooth module is fully qualified **Bluetooth V2.0+EDR (Enhanced Data Rate)** 3Mbps Modulation with complete 2.4GHz radio transceiver and baseband. It uses **CSR Blue core 04** - External single chip Bluetooth system with CMOS technology and with AFH (Adaptive Frequency Hopping Feature).

It is used for many applications like wireless headset, game controllers, wireless mouse, wireless keyboard and many more consumer applications. It has range up to <100m which depends upon transmitter and receiver, atmosphere, geographic & urban conditions.

4.1.4.1 Pin diagram of Bluetooth HC-05

Bluetooth serial modules allow all serial enabled devices to communicate with each other using Bluetooth. It has 6 pins,

1. **Key/EN:** It is used to bring Bluetooth module in AT commands mode. If Key/EN pin is set to high, then this module will work in command mode. Otherwise by default it is in data mode. The default baud rate of HC-05 in command mode is 38400bps and 9600 in data mode.

HC-05 module has two modes,

1. **Data mode:** Exchange of data between devices.

2. **Command mode:** It uses AT commands which are used to change setting of HC-05. To send these commands to module serial (USART) port is used.

2. **VCC:** Connect 5 V or 3.3 V to this Pin.

Fig 4.11 Pin diagram of HC-05

3. **GND:** Ground Pin of module.
4. **TXD:** Transmit Serial data (wirelessly received data by Bluetooth module transmitted out serially on TXD pin)
5. **RXD:** Receive data serially (received data will be transmitted wirelessly by Bluetooth Module).
6. **State:** It tells whether module is connected or not.

HC-05 module

- HC-05 has red LED which indicates connection status, whether the Bluetooth is connected or not. Before connecting to HC-05 module this red LED blinks continuously

in a periodic manner. When it gets connected to any other Bluetooth device, its blinking slows down to two seconds.

- This module works on 3.3 V. We can connect 5V supply voltage as well since the module has on board 5 to 3.3 V regulator.
- As HC-05 Bluetooth module has 3.3 V level for RX/TX and microcontroller can detect 3.3 V level, so, no need to shift transmit level of HC-05 module. But we need to shift the transmit voltage level from microcontroller to RX of HC-05 module.

4.1.4.2 Working principle of HC-05

The Bluetooth module HC-05 is a MASTER/SLAVE module. By default the factory setting is SLAVE. The Role of the module (Master or Slave) can be configured only by AT COMMANDS. The slave modules cannot initiate a connection to another Bluetooth device, but can accept connections. Master module can initiate a connection to other devices. The user can use it simply for a serial port replacement to establish connection between MCU and GPS, PC to your embedded project.

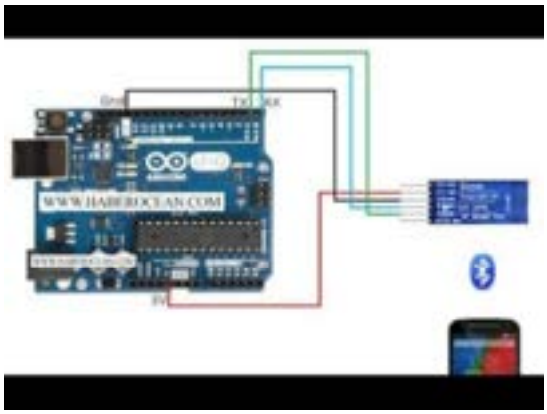

Fig 4.12 Working of Bluetooth

The **HC-05** is a very cool module which can add two-way (full-duplex) wireless functionality to your projects. You can use this module to communicate between two microcontrollers like Arduino or communicate with any device with Bluetooth functionality like

a Phone or Laptop. There are many android applications that are already available which makes this process a lot easier. The module communicates with the help of USART at 9600 baud rate hence it is easy to interface with any microcontroller that supports USART. We can also configure the default values of the module by using the command mode. So if you looking for a Wireless module that could transfer data from your computer or mobile phone to microcontroller or vice versa then this module might be the right choice for you. However do not expect this module to transfer multimedia like photos or songs; you might have to look into the CSR8645 module for that.

4.1.4.3 Program for HC-05 Bluetooth Module

The program given below is the HC-05 Bluetooth module program. This process is quite different from others since we are going to use android mobile to control and communicate with Arduino. Here the Bluetooth module acts as an interface between our mobile and Arduino board. Before getting into the execution process, follow the given procedure:

- First of all, the user should install an application called **Bluetooth SPP PRO** from the play store which is a free application.
- After installation, pair the Bluetooth module to your mobile as like connecting one device to other using Bluetooth. The default pairing code is **1234**.
- Upload the given program to the Arduino Uno board. After uploading the code, unplug the USB from the Arduino.
- Now use external power adapter to power the Uno board.
- The Bluetooth SPP PRO has three types of communication mode. Here Byte stream mode is used to communicate. So select that mode and give the input as **1**, as soon as the input has given the led will turn on and for **0** led will turn off.

Command Mode

- When we want to change settings of HC-05 Bluetooth module like change password for connection, baud rate, Bluetooth device's name etc.
- To do this, HC-05 has AT commands.
- To use HC-05 Bluetooth module in AT command mode, connect "Key" pin to High (VCC).
- Default Baud rate of HC-05 in command mode is 38400bps.
- Following are some AT command generally used to change setting of Bluetooth module.
- To send these commands, we have to connect HC-05 Bluetooth module to the PC via serial to USB converter and transmit these command through serial terminal of PC.

4.1.4.4 Features of HC-05

Hardware Features

- Typical - 80dBm sensitivity.
- Up to +4dBm RF transmit power.
- 3.3 to 5V I/O.
- PIO (Programmable Input/Output) control.
- UART interface with programmable baud rate.
- With integrated antenna.
- With edge connector.

Software Features

- Slave default Baud rate: 9600, Data bits:8, Stop bit:1,Parity:No parity.
- Auto - connect to the last device on power as default.
- Permit pairing device to connect as default.
- Auto - pairing PINCODE:" 1234" as default.

4.1.4.5 Specification of HC-05

Modulation	GFSK(Gaussian Frequency Shift Keying)
Operating Voltage	3.3V
Operating Frequency band	2.4 GHZ ISM band
Flash memory Size	8-bit
Emission Power	≤4dBm
Sensitivity	≤-84dBm at 0.1% BER
Speed Asynchronous	2.1Mbps(Max)/160 Kbps
Speed Synchronous	1Mbps/1Mbps

4.1.5 LCD Display

16×2 LCD is named so because; it has 16 Columns and 2 Rows. There are a lot of combinations available like, 8×1, 8×2, 10×2, 16×1, etc. But the most used one is the 16*2

LCD, hence we are using it here. All the above mentioned LCD display will have 16 Pins and the programming approach is also the same and hence the choice is left to you. We come across LCD displays everywhere around us. Computers, calculators, television sets, mobile phones, digital watches use some kind of display to display the time. An LCD is an electronic display module which uses liquid crystal to produce a visible image. The 16×2 LCD display is a very basic module commonly used in DIYs and circuits. The 16×2 translates of a display 16 characters per line in 2 such lines. In this LCD each character is displayed in a 5×7 pixel matrix.

Fig 4.13 LCD Display

If you can see starting addresses for each character with their printing commands. The first character is generated at address 0x40 to 0x47 and is printed on LCD by just sending simple command 0 to the LCD. The second character is generated at address 0x48 to 0x55 and is printed Generating custom characters on LCD is not very hard. It requires the knowledge about custom generated random access memory (CG-RAM) of LCD and the LCD chip controller. Most LCDs contain Hitachi HD4478 controller. CG-RAM size is 64 byte providing the option of creating eight characters at a time. Each character is eight byte in size. CG-RAM address starts from 0x40 (Hexadecimal) or 64 in decimal. We can generate custom characters at these addresses.

4.1.5.1 Pin diagram of LCD display

In pin no 1 is consists of Ground is Ground (0V). If pin no 2 is represents Supply voltage for LCD display 5V (4.7V – 5.3V) Vcc. In pin no 3 is VO / VEE Contrast adjustment; the best way is to use a variable resistor such as a potentiometer. The output of the potentiometer is connected to this pin. Rotate the potentiometer knob forward and backwards to adjust the

LCD contrast. Pin no 4 is RS (Register Select) Selects command register when low, and data register when high**.** Pin no 5 is consists of Read/write Low to write to the register; High to read from the register.

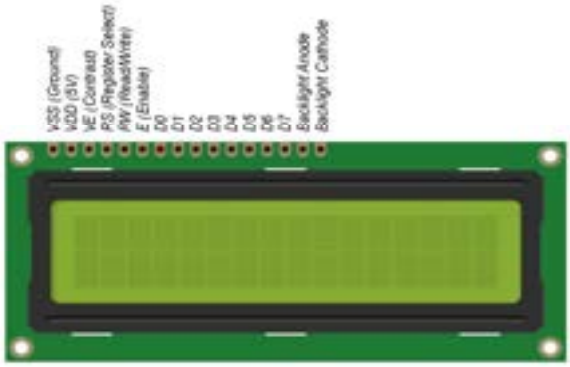

Fig 4.14 Pin diagram of LCD

In pin no 6 is Enable Sends data to data pins when a high to low pulse is given; Extra voltage push is required to execute the instruction and EN (enable) signal is used for this purpose. Usually, we make it en=0 and when we want to execute the instruction we make it high en=1 for some milliseconds. After this we again make it ground that is, en=0.In pin no 7 to 14 is namely as, DB0 to DB7 is 8-bit data pins. Pin no 15 is Led+ Backlight VCC (5V). Pin no 16 is Led- consists Backlight Ground (0V).

RS (Register select)

A 16X2 LCD has two registers, namely, command and data. The register select is used to switch from one register to other. RS=0 for command register, whereas RS=1 for data register.

Command Register

The command register stores the command instructions given to the LCD. A command is an instruction given to LCD to do a predefined task like initializing it, clearing its screen, setting the cursor position, controlling display etc. Processing for commands happens in the command register.

Data Register

The data register stores the data to be displayed on the LCD. The data is the ASCII value of the character to be displayed on the LCD. When we send data to LCD it goes to the data register and is processed there. When RS=1, data register is selected.

4.1.5.2 features of LCD Display

- Operating voltage is 4.7 to 5.3 v.
- Current consumption is 1mA without backlight.
- Alphanumeric LCD Display module, meaning can display alphabets and numbers.
- Can work on both 8-bit and 4- bit.

4.1.5.3 Specification of LCD Display

- The 16*2 LCD Display is a very basic module commonly used in DIYs and circuit.
- The 16*2 translates 0 a display 16 character per line in 2 such lines.
- In this LCD each character is displayed in 5*7 pixel matrix.

4.1.6 Transformer

Step down the voltage level 230V AC is converted into 12V AC using a step down transformer. 12V output of step down transformer is an RMS value and its peak value is given by the product of square root of two with RMS value, which is approximately 17V.

To identify which side primary follow either any one steps. Step down transformer are used in interconnection of transmission system with different voltage level. They decrease voltage level from high to lower level value. These transformer are huge and have very high nominal power (even 1000 MVA).The transformers are designed for either single-phase supply or three-phase supply. It may be either step up or step down transformer. However, the **working principle of**

step down transformer and all these transformers are the same and that is electromagnetic induction.

A transformer consists of two highly inductive coils (windings) wound on a steel or iron core. The winding connected to the AC supply is known as primary winding whereas the winding connected to the load is known as secondary winding. The primary and secondary windings are isolated from each other as well as from the iron core electrically. The electrical power is transferred from primary circuit to secondary circuit by magnetic flux

Fig 4.15 Step down transformer

If you have multi meter check the resistance, primary side will have higher resistance and secondary will have lower resistance (Sometimes you may not notice the difference as you might be using transformer for smaller size) Or else if possible supply lower AC voltage on either side or check the output on other side. By that you can identify which side is stepping down.

4.1.6.1 Working principle of step down transformer

When the primary winding is connected to the AC supply an AC current starts flowing through it. The AC current of primary winding produces an alternating flux φ in the core. Most of this alternating flux links with secondary winding through the core. This alternating flux induces a voltage into the secondary winding according to the Faraday's law of electromagnetic induction.

The EMF is induced in the secondary winding is due to mutual induction hence it is known as mutually induced EMF. The induced EMF in the secondary and primary depends

upon the rate of change of flux linkages (Ndφ/dt). The rate of change of flux in secondary and primary circuit is the same. Therefore, induced EMF in secondary is proportional to number of turns of the secondary winding (E2 α N2) and in primary is proportional to number of turns of primary (E1 α N1).

A transformer changes only current and voltage levels of AC supply. It does not have any effect on the frequency of AC supply. It can be operated only on AC supply. If a transformer is connected to the DC supply, a large amount of current will flow through the primary winding and it can damage the transformer winding.

4.1.6.2 Convert of 230V to 12V

1. **Transformer:** Connect 230V AC to a 230 to 30V step down transformer. After this you will get a 30V pullulating AC voltage.

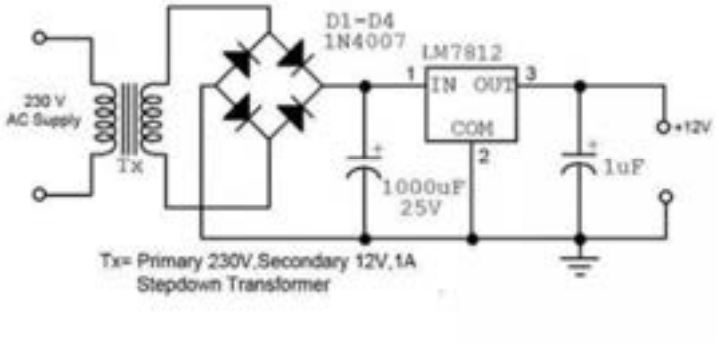

Fig 4.16 Conversion of 230V to 12V

2. **Rectify:** Connect a bridge made up of four Diodes. The output will be 2*VP/pi, which is 19.10V.

3. **Filter:** Connect a filter, which filters out ripples from the signal. Usually a capacitor or Inductor is used. The output will be around 19V with little ripples.
4. **Regulate:** Connect a LM317, and regulate the output to 12V. You will get a smooth 12V regulated DC output.

4.1.6.3 Specification of Transformer

voltage level	230V to 12V
Output Voltage	12V
Maximum of current level	1mA
RMS Value	17V

4.1.7.1 Cloud Computing

Cloud computing is the on-demand availability of computer system resources, especially data storage and computing power, without direct active management by the user. The term is generally used to describe data centers available to many users over the Internet. Large clouds, predominant today, often have functions distributed over multiple locations from central servers. If the connection to the user is relatively close, it may be designated an edge server.

Clouds may be limited to a single organization (enterprise clouds), or be available to many organizations (public cloud). Cloud computing relies on sharing of resources to achieve coherence and economies of scale.

Fig 4.17 Cloud Computing

Advocates of public and hybrid clouds note that cloud computing allows companies to avoid or minimize up-front IT infrastructure costs. Proponents also claim that cloud computing allows enterprises to get their applications up and running faster, with improved manageability and less maintenance, and that it enables IT teams to more rapidly adjust resources to meet fluctuating and unpredictable demand, providing the burst computing capability: high computing power at certain periods of peak demand Cloud providers typically use a "pay-as-you-go" model, which can lead to unexpected operating expenses if administrators are not familiarized with cloud-pricing models.

The availability of high-capacity networks, low-cost computers and storage devices as well as the widespread adoption of hardware virtualization, service-oriented architecture and autonomic and utility computing has led to growth in cloud computing. By 2019, Linux was the most widely used operating system, including in Microsoft's offerings and is thus described as dominant.

4.1.7.2 Public cloud

For a comparison of cloud-computing software and providers, see Cloud-computing comparison A cloud is called a "public cloud" when the services are rendered over a network that is open for public use. Public cloud services may be free.[89] Technically there

may be little or no difference between public and private cloud architecture, however, security consideration may be substantially different for services (applications, storage, and other resources) that are made available by a service provider for a public audience and when communication is effected over a non-trusted network. AWS, Oracle, Microsoft, and Google also offer direct connect services called "AWS Direct Connect", "Oracle Fast Connect", "Azure ExpressRoute", and "Cloud Interconnect" respectively, such connections require customers to purchase or lease a private connection to a peering point offered by the cloud provider.

4.2 Software Explanation

4.2.1 Windows 7

Windows 7 is a personal computer operating system that was produced by Microsoft as part of the Windows NT family of operating systems. It was released to manufacturing on July 22, 2009, and became generally available on October 22, that year less than three years after the release of its predecessor, Windows Vista. Windows 7's server counterpart, Windows Server 2008 R2, was released at the same time. Microsoft ended mainstream support for Windows 7 on January 13, 2015 and extended support ended on January 14, 2020.

Fig 4.18 Windows 7

Windows 7 was primarily intended to be an incremental upgrade to Microsoft Windows, addressing Windows Vista's poor critical reception while maintaining hardware and software compatibility. Windows 7 continued improvements on Windows Aero (the user interface introduced in Windows Vista) with the addition of a redesigned taskbar that allows applications to be "pinned" to it, and new window management features. Other new features were added to the operating system, including libraries, the new file sharing system Home Group, and support for multitouch input. A new "Action Center" interface was also added to provide an overview of system security and maintenance information, and tweaks were made to the User Account Control system to make it less intrusive.

Windows 7 was a major success for Microsoft; even prior to its official release, pre-order sales for the operating system on the online retailer Amazon.com had surpassed previous records. In just six months, over 100 million copies had been sold worldwide, increasing to over 630 million licenses by July 2012. As of January 2020, 26.79% of traditional PCs running Windows are running Windows 7 (and thus 21% of all traditional PCs) which still has over 60% market share in some countries.

Windows 7 includes 13 additional sound schemes, titled Afternoon, Calligraphy, Characters, Cityscape, Delta, Festival, Garden, Heritage, Landscape, Quirky, Raga, Savanna, and Sonata. Internet Spades, Internet Backgammon and Internet Checkers, which were removed from Windows Vista, were restored in Windows 7. Users are able to disable or customize many more Windows components than was possible in Windows Vista. New additions to this list of components include Internet Explorer 8, Windows Media Player 12, Windows Media Center, Windows Search, and Windows Gadget Platform67 A new version of Microsoft Virtual PC, newly renamed as Windows Virtual PC was made available for Windows 7 Professional, Enterprise, and Ultimate editions. It allows multiple Windows environments, including Windows XP Mode, to run on the same machine. Windows XP Mode runs Windows XP in a virtual machine, and displays applications within separate windows on the Windows 7 desktop. Furthermore, Windows 7 supports the mounting of a virtual hard disk (VHD) as a normal data storage, and the bootloader delivered with Windows 7 can boot the Windows system from a VHD; however, this ability is only available in the Enterprise and Ultimate editions70 The Remote Desktop Protocol (RDP) of Windows 7 is also enhanced to support real-time

multimedia application including video playback and 3D games, thus allowing use of DirectX 10 in remote desktop environments.

4.2.1.1 Service Pack 1

Windows 7 Service Pack 1 (SP1) was announced on March 18, 2010. A beta was released on July 12, 2010. The final version was released to the public on February 22, 2011.[133] At the time of release, it was not made mandatory. It was available via Windows Update, direct download, or by ordering the Windows 7 SP1 DVD. The service pack is on a much smaller scale than those released for previous versions of Windows, particularly Windows Vista.

Windows 7 Service Pack 1 adds support for Advanced Vector Extensions (AVX), a 256-bit instruction set extension for processors, and improves IKEv2 by adding additional identification fields such as E-mail ID to it. In addition, it adds support for Advanced Format 512e as well as additional Identity Federation Services. Windows 7 Service Pack 1 also resolves a bug related to HDMI audio and another related to printing XPS documents.

In Europe, the automatic nature of the BrowserChoice.eu feature was dropped in Windows 7 Service Pack 1 in February 2011 and remained absent for 14 months despite Microsoft reporting that it was still present, subsequently described by Microsoft as a "technical error". As a result, in March 2013 the European Commission fined Microsoft €561 million to deter companies from reneging on settlement promises.

4.2.1.2 Platform Update

The Platform Update for Windows 7 SP1 and Windows Server 2008 R2 SP1 was released on February 26, 2013 after a pre-release version had been released on November 5, 2012. It is also included with Internet Explorer 10 for Windows 7.

It includes enhancements to Direct2D, Direct Write, Direct3D, Windows Imaging Component (WIC), Windows Advanced Rasterization Platform (WARP), Windows Animation Manager (WAM), XPS Document API, H.264 Video Decoder and JPEG XR

decoder. However support for Direct3D 11.1 is limited as the update does not include DXGI/WDDM 1.2 from Windows 8, making unavailable many related APIs and significant features such as stereoscopic frame buffer, feature level 11_1 and optional features for levels 10_0, 10_1 and 11_0.

4.2.1.3 Disk Cleanup update

In October 2013, a Disk Cleanup Wizard addon was released that lets users delete outdated Windows updates on Windows 7 SP1, thus reducing the size of the WinSxS directory. This update backports some features found in Windows 8.

4.2.1.4 Windows Management Framework 5.0

Windows Management Framework 5.0 includes updates to Windows PowerShell 5.0, Windows PowerShell Desired State Configuration (DSC), Windows Remote Management (WinRM), Windows Management Instrumentation (WMI).

4.2.1.5 Convenience rollup

In May 2016, Microsoft released a "Convenience rollup update for Windows 7 SP1 and Windows Server 2008 R2 SP1", which contains all patches released between the release of SP1 and April 2016. The rollup is not available via Windows Update, and must be downloaded manually. This package can also be integrated into a Windows 7 installation image.

Since October 2016, all security and reliability updates are cumulative. Downloading and installing updates that address individual problems is no longer possible, but the number of updates that must be downloaded to fully update the OS is significantly reduced.

4.2.1.3 System Requirements

Component	Operating system architecture	
	32-bit	**64-bit**
Processor	1 GHz IA-32 processor	1 GHz x86-64 processor
Memory (RAM)	1 GB	2 GB
Graphics card	DirectX 9 graphics processor with WDDM driver model 1.0	
Storage space	16 GB	20 GB
Installation media	DVD drive or USB drive	

4.2.2 Visual studio

Microsoft Visual Studio is an integrated development environment (IDE) from Microsoft. It is used to develop computer programs, as well as websites, web apps, web services and mobile apps. Visual Studio uses Microsoft software development platforms such as Windows API, Windows Forms, Windows Presentation Foundation, Windows Store and Microsoft Silverlight. It can produce both native code and managed code.

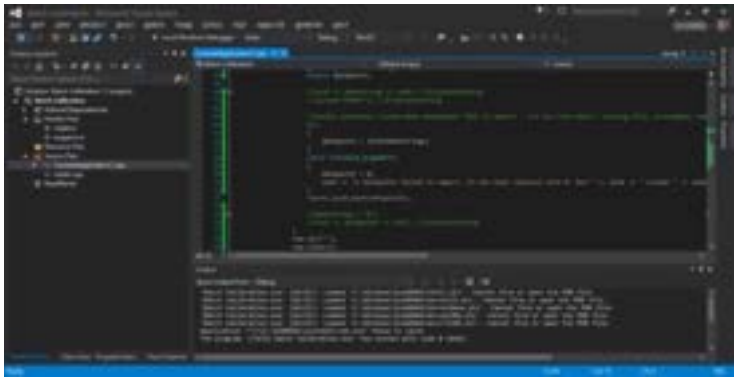

Fig 4.19 Visual studio

Visual Studio includes a code editor supporting IntelliSense (the code completion component) as well as code refactoring. It accepts plug-ins that enhance the functionality at almost every level including adding support for source control systems (like Subversion and Git) and adding new toolsets like editors and visual designers for domain-specific languages or toolsets for other aspects of the software development lifecycle.

Visual Studio supports 36 different programming languages and allows the code editor and debugger to support (to varying degrees) nearly any programming language, provided a language-specific service exists. Built-in languages include C, C++, C++/CLI, Visual Basic .NET, C#, F#, JavaScript, Typescript, XML, XSLT, HTML, and CSS. The most basic edition of Visual Studio, the Community edition, is available free of charge. The slogan for Visual Studio Community edition is "Free, fully-featured IDE for students, open-source and individual developers". The currently supported Visual Studio version is 2019.

4.2.2.1 Architecture

Visual Studio does not support any programming language, solution or tool intrinsically; instead, it allows the plugging of functionality coded as a VSPackage. When installed, the functionality is available as a Service. SVsUIShell, which provides windowing and UI functionality (including tabs, toolbars, and tool windows); and SVsShell, which deals with registration of VSPackages. In addition, the IDE is also responsible for coordinating and enabling communication between services. All editors, designers, project types and other tools are implemented as VSPackages. Visual Studio uses COM to access the VSPackages. The Visual Studio SDK also includes the Managed Package Framework (MPF). The services can then be consumed for creation of other packages, which add functionality to the Visual Studio IDE.

4.2.2.2 Code editor

The Visual Studio code editor also supports setting bookmarks in code for quick navigation. Other navigational aids include collapsing code blocks and incremental search, in

addition to normal text search and regex search. The code editor also includes a multi-item clipboard and a task list. The code editor supports code snippets, which are saved templates for repetitive code and can be inserted into code and customized for the project being worked on. A management tool for code snippets is built in as well. These tools are surfaced as floating windows which can be set to automatically hide when unused or docked to the side of the screen. The Visual Studio code editor also supports code refactoring including parameter reordering, variable and method renaming, interface extraction, and encapsulation of class members inside properties, among others.

4.2.2.3Designer

Visual Studio includes a host of visual designers to aid in the development of applications. These tools include

4.2.2.4 Windows Forms Designer

The Windows Forms designer is used to build GUI applications using Windows Forms. Layout can be controlled by housing the controls inside other containers or locking them to the side of the form. Controls that display data (like textbox, list box and grid view) can be bound to data sources like databases or queries. Data-bound controls can be created by dragging items from the Data Sources window onto a design surface.. The designer generates either C# or VB.NET code for the application.

4.2.2.5 WPF Designer

The WPF designer, codenamed Cider, was introduced with Visual Studio 2008. Like the Windows Forms designer it supports the drag and drop metaphor. It is used to author user interfaces targeting Windows Presentation Foundation. It supports all WPF functionality including data binding and automatic layout management. It generates XAML code for the UI. The generated XAML file is compatible with Microsoft Expression Design, the designer-oriented product. The XAML code is linked with code using a code-behind model.

4.2.2.6 Web designer/development

Visual Studio also includes a web-site editor and designer that allows web pages to be authored by dragging and dropping widgets. It is used for developing ASP.NET applications and supports HTML, CSS and JavaScript. It uses a code-behind model to link with ASP.NET code. From Visual Studio 2008 onwards, the layout engine used by the web designer is shared with Microsoft Expression Web. There is also ASP.NET MVC support for MVC technology as a separate download and ASP.NET Dynamic Data project available from Microsoft.

4.2.2.7 Class designer

The Class Designer is used to author and edit the classes (including its members and their access) using UML modeling. The Class Designer can generate C# and VB.NET code outlines for the classes and methods. It can also generate class diagrams from hand-written classes.

4.2.2.8 Data designer

The data designer can be used to graphically edit database schemas, including typed tables, primary and foreign keys and constraints. It can also be used to design queries from the graphical view.

4.2.2.9 Mapping designer

From Visual Studio 2008 onwards, the mapping designer is used by LINQ to SQL to design the mapping between database schemas and the classes that encapsulate the data. The new solution from ORM approach, ADO.NET Entity Framework, replaces and improves the old technology.

4.2.3 Embedded C

Embedded C is a set of language extensions for the C programming language by the C Standards Committee to address commonality issues that exist between C extensions for different embedded systems.Embedded C programming typically requires nonstandard extensions to the C language in order to support enhanced microprocessor features such as fixed-point arithmetic, multiple distinct memory banks, and basic I/O operations.

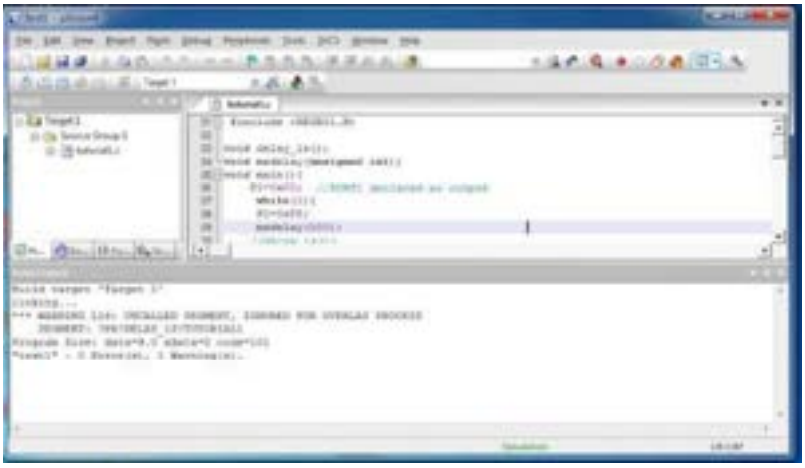

Fig 4.20 Embedded C

In 2008, the C Standards Committee extended the C language to address such capabilities by providing a common standard for all implementations to adhere to. It includes a number of features not available in normal C, such as fixed-point arithmetic, named address spaces and basic I/O hardware addressing. Embedded C uses most of the syntax and semantics of standard C, e.g., main () function, variable definition, datatype declaration, conditional statements (if, switch case), loops (while, for), functions, arrays and strings, structures, structures and union, bit operations, macros, etc. A Technical Report was published in 2004 and a second revision in 2006.

CHAPTER 5

RESULT AND DISCUSSION

5.1 Result and Discussion

Science and technology is panacea for all our growing problems. Predicting the natural processes are highly complex and our system needs to be tested against real time conditions.. The system needs to be robust to withstand all the climate changes which may affect its functioning. However, our system will play a crucial role in curbing the forest fires which would prevent loss of huge resources and financial losses. We have tested in forest like conditions, but real hardship which we may face is during implementation in large area in real it. Forest is a very important and grow in many places in around world. In a forest is piece of land with many trees. Many animals to live and survive the forest. Forest also used to prevent soil erosion, climate changes. This paper, a cloud based forest fire alert system using IOT technology. Temperature is increased or smoke typically fire indicate to LCD display. The real time sense a data will send and stored cloud. Finally information of the different parameter to be monitor forest officer and nearby forest survival peoples.

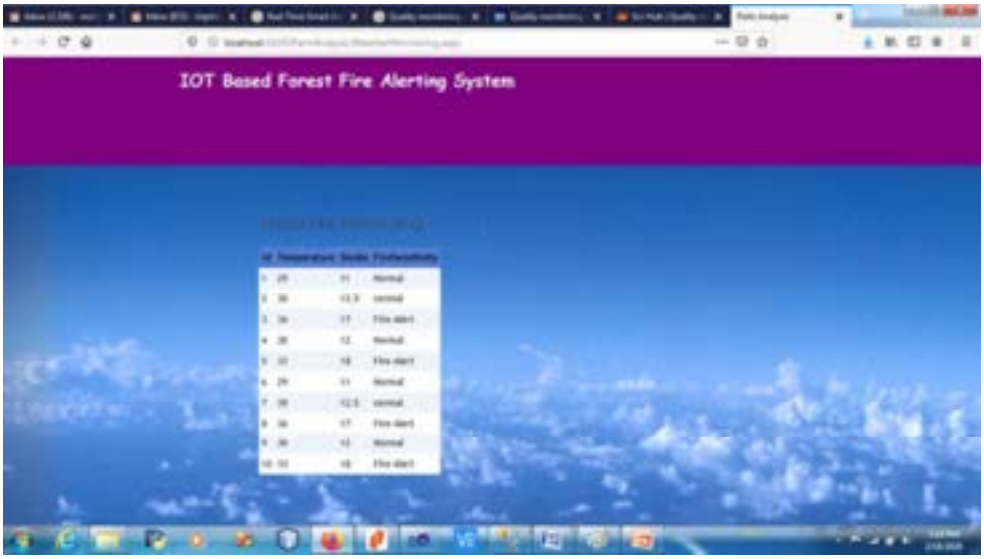

Fig 5.1 output of the system

CHAPTER 6

CONCLUSION AND FUTURE ENHANCEMENT

6.1 Conclusion

Forest and land fires in direct and indirect well recognized as one of the main contributor to deforestation and land conversion which responsible for mostly of greenhouse gas produced which finally related with the global climate change. Forest fire is a multi-sector issues. To solve the problem, reduction of forest and land fire occurs and land conversion hopefully is one of the reasonable action and prevention efforts is the best solution through community involvement. The national forest commission, has recommended creating an enabling environment to facilitate assessment, monitoring and reporting on national level criteria and indicators for sustainable forest management. A large data base can be achieved over the entire fire season for further evaluations and research activities.so this project developed in cloud based forest fire alert system using IOT. To managing the storing a data and communicating the information.

6.2 Future Enhancement

1. Fire accidents can be controlled to a great extent in a places such as forests, homes, Colleges, Industries, trains and some other public places.
2. Fire accidents leads to death of excess of People, by using this technique we can save Those Life's easily.

Cloud Based Forest Fire Alert System Using Iot

Ajith.S[1], chandru.S[2], Boopalan.E[3],

Dept of Electronics and Communication Engineering,

Associate professor **Periyathambi.P[4]** Dept of Electronics and Communication Engineering,

Paavai engineering college, Namakkal, Tamil Nadu.

ABSTRACT

The most common hazard in forest fire Accident are themselves destroy the forest and great threat for wildlife and peoples. The number of trees has reduced drastically so the forest are creates an unhealthy environment for animals to survive in the forest. Forest covers 31% of the world and 21% of the India. It has found in a survey that 80% of losses are caused due to fire. This project of a system fire was detected early stages. It was tracking and alarming for protection of trees against forest fire. Now IOT (Internet of things) devices and cloud based to forest fire alerting system. If cloud can used to storing the information of data to monitoring the different environmental variables such as temperature, smoke, moisture of the forest. So finally to prevent the fire to spread over a huge area and precaution the forest**.**

KEYWORD: *Arduino UNO atmega328p, temperature sensor, smoke sensor, LCD Display, mobile Wireless communication.*

I. INTRODUCTION

Forest fire detection become one such issue. Due to forest fire has caused serious environmental Problems and devastation of flora fauna. The current turbulent global economic, demographic, social and ecologic context, government, local administrative authorities and commercial companies or individuals have the importance resources contained in forest environment. Forest ecosystems are dynamic and complicated. Disturbance to any part of network affect the balance of relationship and equally complete scheme either absolutely or negativity.so global climate change, drought and different conditions have caused occurrence of wildfire to extend, once wildfire occur it takes years to naturally recover. Forest fire is an uncontrolled fire occurring in nature and man-made. Once fire starts ignited it rapidly spreads all over area in the forest. The land were forest is burnt it became impossible to grow vegetation over there. This is because soil becomes water repelled and accepts no more water. Leading to reduction of ground water level. Fire causes huge loss of lives and properties every year. The national crime records Bureau indicates that there have been of 113972 fatalities due to fire accidents of the year 2010 to 2014.one of the most destructive properties of fire is that it spreads exponentially and with the right medium can spread uncontrollably. This is why timely detection of fire of fire is necessary for avoiding a fire hazard. The internet of things is a collection of sensor, actuators, software, embedded with electronics, connect each other with cloud. It is an also economic benefits. IOT make everyday life easier for humans by developing smart devices. If increased IOT devices 31% at 8.4 billion in the year 2017. IOT involves connecting objects beyond the range of standard device which are used for every day purpose. The Arduino UNO at mega 328p for open platform for IOT to program easily and IOT devices also used to interface the embedded system and application of users. Temperature sensor used to measure the temperature level, smoke sensor is used find smoke type of quantities. If cloud to communication the devices.

II. PROPOSED SYSTEM

The proposed system is cloud based forest fire alert system using IOT technology. In the advancing world, it is very crucial to protect our environment. The fire cause serious change and disturbance to wildlife and human life. In wild animals are most affected and die also known for forest fire. If forest trees also burned to affect atmosphere, environment. This fire made naturally and man-made. So this project need to prevent and pre-cautions from forest fire. In order to achieve the best fire detection result with faster time to detect the temperature variation. When temperature sensor used to measure the temperature variation. Smoke sensor is a device that dense smoke, typically as an indicator of fire. Arduino at mega 328p used to control and monitor

the activities. Cloud is a storage purpose to use him. Because each and every second to monitoring the environment condition data can be stored. IOT Device to interface with Arduino and cloud.so finally fix the monitoring system done in nearby forest office station. The detail about the system is connected with a computer system monitored by the officer.

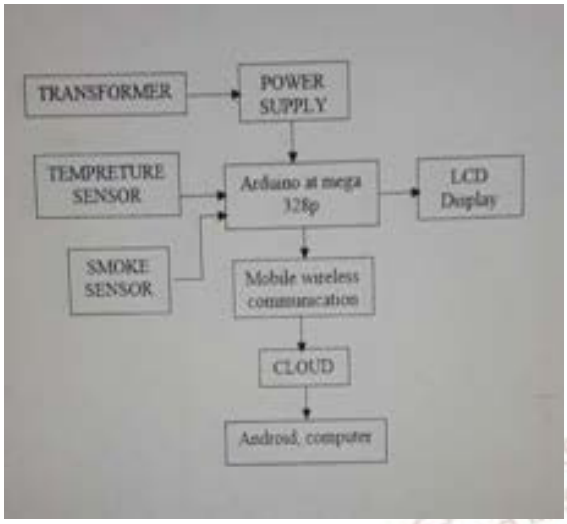

Fig 1. Block Diagram

III. HARDWARE IMPLEMENTATION

A. TEMPRATURE SENSOR

Temperature sensor normally used to measure variation of the temperature in particular area in range. In LM35 is basic temperature sensor that can be used for experimental purpose.

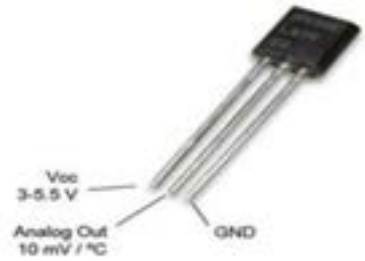

Fig 2. Temperature sensor

In this sensor output voltage value directly linear propositional to the Degree Celsius (centigrade). The advantage of this sensor more memory processing and communication capabilities. Power supply is -2 to 35v and temperature Range -55^0 to 150^0c.

B. SMOKE SENSOR

Smoke sensor mq-2 is used to detect smoke and flammable combustible gasses in atmosphere. Good sensitivity to alcohol in wide range, long life line, low cost. Output is a reading in analog voltage. The sensor measure of flammable gas range is 200 to 1000 ppm. Operating voltage 5v.

Fig 3. Smoke sensor

C. BLUETOOTH

The Bluetooth HC-05 is a very cool module which add two way wirelessly functionally the project. It connect a small devices like TV, mobile phones. It is easy to use serial port protocol. Operating frequency band is 2.4 GHZ. Flash memory size is 8-bit. And operating voltage is 3.3v.

Fig 4. Bluetooth

D. ARDUINO ATMEGA 328P

Arduino at mega 328p is an open source electronics platform. The main advantage is easy to use hardware and software. It has 14 digital input/output. At mega 328p is an 8-bit micro controller based on AVR RISC. So preparing this microcontroller for flashing the Arduino bootloader. Operating voltage is 5v and the clock speed is 16MHZ.

Fig 5. Arduino At mega 328p

E. LCD DISPLAY

An LCD is an electronic display. Which uses liquid crystalline display produces a visible image. The 16*2 LCD Display is very basic module commonly used for DIYs and circuit. Which translates the 16 character per 2 such a line. In advantage is sharpness, brightness, high peak intensity produces. Operating voltage is 4.7v to 5.3v.

Fig 6. LCD Display

F. CLOUD

Cloud is a very important big level storage place and interconnect the computer, mobile phones with internet. Cloud is mainly used to storage the data and information will be shared.

Fig 7. Cloud computing

If embedded system sends the monitoring data to server access and maintained. In public cloud use the project to server to provide the information via internet.

IV. CONCLUTION

Forest is a very important and grow in many places in around world. In a forest is piece of land with many trees. Many animals to live and survive the forest. Forest also used to prevent soil erosion, climate changes. This paper, a cloud based forest fire alert system using IOT technology. Temperature is increased or smoke typically fire indicate to LCD display. The real time sense a data will send and stored cloud. Finally information of the different parameter to be monitor forest officer and nearby forest survival peoples.

SEPTEMBER 2020

ABSTRACT

Achieving reliable routing has always been a major issue in the design of communication networks, among which mobile ad hoc networks (MANETs) possess the most adversarial networking environment due to the absence of fixed infrastructure, the nature of open transmission media and the dynamic network topology. These characteristics also make the design of routing protocols in MANETs become even more challenging. Determining feasible routing paths for distributing messages in a decentralized network where network topology varies is a difficult job. Factors such as the open medium and vast distribution of nodes, topological changes, variable wireless link quality, and propagation path loss become pertinent issues and make MANET unprotected to instructions. Thus, it becomes pivotal to develop a systematic intrusion detection scheme to secure Mobile Ad Hoc networks from intruders. In this project, we put forward and applied an efficient IDS mechanism based on Enhanced Adaptive Acknowledgment (EAACK) especially made for MANETs which performs better than the previous techniques such as Watchdog, TWOACK and AACK.

CHAPTER 1

INTRODUCTION

Introduction

Wireless networking is the need of hour for many applications because of its easier network expansion, increased mobility improved responsiveness, better access to information, and enhanced guest access. In addition, with the increasing standard of industry and use of lightweight network hardware devices that are even smaller and largely mobile. The wireless communication is enhanced by Mobile ad hoc networks (MANETs) having high degree of node mobility.

1.1 Mobile Adhoc Network (MANETS)

Wireless cellular systems have been in use since 1980s. We have seen their evolutions to first, second and third generation's wireless systems. Wireless systems operate with the aid of a centralized supporting structure such as an access point. These access points assist the wireless users to keep connected with the wireless system, when they roam from one place to the other. The presence of a fixed supporting structure limits the adaptability of wireless systems. In other words, the technology cannot work effectively in places where there is no fixed infrastructure. Future generation wireless systems will re quire easy and quick deployment of wireless networks. This quick network deployment is not possible with the existing structure of current wireless systems. The next generation of wireless communication systems, there will be a need for the rapid deployment of independent mobile users. Significant examples include establishing survivable, efficient, dynamic communication for emergency/rescue operations, disaster relief efforts, and military networks. Such network scenarios cannot rely on centralized and organized connectivity, and can be conceived as applications of Mobile Ad Hoc Networks. Mobile ad-hoc networks or "short live" networks operate in the absence of fixed infrastructure. They offer quick and easy network deployment in situations where it is not possible otherwise. Ad-hoc is a Latin word, which means "for this or for this only."

Mobile ad-hoc network is an autonomous system of mobile nodes connected by wireless links; each node operates as an end system and a router for all other nodes in the network.

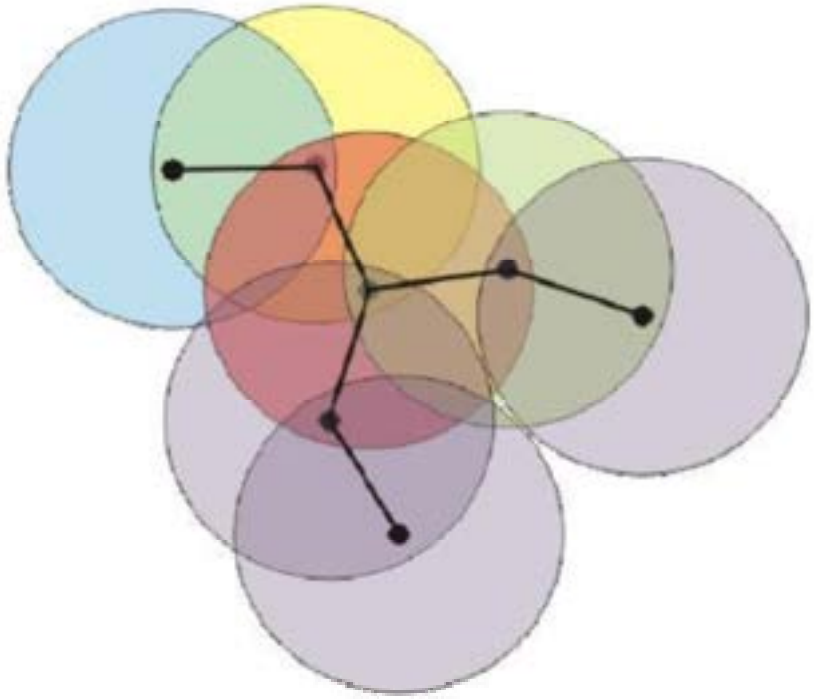

Figure1.1 Manet Structure

MANET is an autonomous collection of mobile users that communicate over relatively bandwidth constrained wireless links. Since the nodes are mobile, the network topology may change rapidly and unpredictably over time. The network is decentralized, where all network activity including discovering the nodes themselves must execute the topology and delivering messages, i.e., routing functionality will be incorporated into mobile nodes. The set of applications for MANETS is diverse, ranging from small, static networks that are constrained by power sources, to large-scale, mobile, highly dynamic networks. The design of network protocols for these networks is a complex issue. Regardless of the application, MANETS need efficient distributed algorithms to determine network organization, link scheduling, and routing. However, determining viable routing paths and delivering messages in a decentralized environment where network topology fluctuates is not a well-defined problem. While the shortest path (based

on a given cost function) from a source to a destination in a static network is usually the optimal route, this idea is not easily extended to MANETS. Factors such as variable wireless link quality, propagation path loss, fading, multi-user interference, power expended, and topological changes, become relevant issues. The network should be able to adaptively alter the routing paths to alleviate any of these effects. Moreover, in a military environment, preservation of security, latency, reliability, intentional jamming, and recovery from failure are significant concerns. Military networks are designed to maintain a low probability of intercept and/or a low probability of detection. Hence, nodes prefer to radiate as little power as necessary and transmit as infrequently as possible, thus decreasing the probability of detection or interception. A lapse in any of these requirements may degrade the performance and dependability of the network.

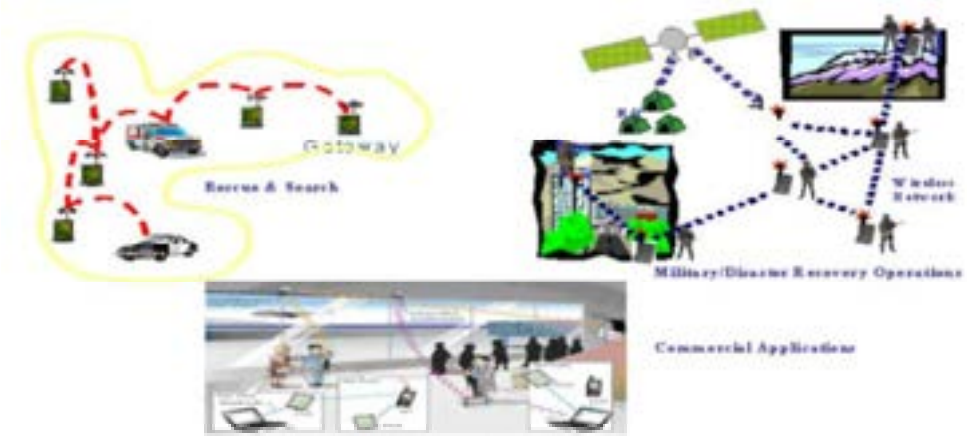

Figure 1.2 Mobile Ad Hoc Network Applications

Mobile ad-hoc network (MANET) is ideally to be used in emergency situations like natural disasters, military conflicts, emergency medical situations etc as shown in Fig1.2

1.2 Routing in Ad-Hoc Networks

Mobile Ad-Hoc networks (MANETS) are by definition peer-to-peer, multi-hop networks, without any existing infrastructure. If a network host wishes to communicate with another network host that is outside its radio range, it must use intermediate hosts to route the communications. Therefore routing functionality needs to

be incorporated into the mobile hosts. Note: - Because of the common distinction between hosts and routers in networking documentation, the term mobile node shall be used from here on. In wired networks routing algorithms are categorized as link state based protocols (e.g. OSPF Open Short Path First) or distance vector based (e.g. RIP Routing Information Protocol). The link state protocols use the Dijkstra algorithm. Link state advertisements are sent to all network routers. The routers accumulate link-state information and the Dijkstra algorithm is used to calculate the shortest path to each node. The distance vector based protocols use the Bellman-Ford algorithm. These call for routers to distribute their routing table, but only to their neighbors. The Bellman-Ford algorithm can be used to maintain and update routing information in a wireless network, where there is not a high degree of mobility. However, when a high degree of mobility is introduced, Bellman-Ford protocols are not able to catch up with the frequent link changes and resulting in poor network convergence and low communication throughput. In the design of routing protocols for mobile ad-hoc networks, the following are desirable factors: -

(1) Distributed operation With no central hierarchy of routers, routing must be distributed amongst the participant nodes.

(2) Loop-freedom Aim to avoid route discovery or maintenance processes from spinning from node to node indefinitely.

(3) Demand-based operation versus Proactive operation Are routes to be determined as a source requires it or should a pre-defined current table of routes be distributed amongst nodes? Both approaches are taken in adhoc networks and protocols fall into either of these two categories.

(4) "Sleep" period operation To conserve energy, it is desirable that when a node is not actively participating on a network, should be able to enter a 'sleep' state. The routing protocol should be able to accommodate such periods without major impact on operation.

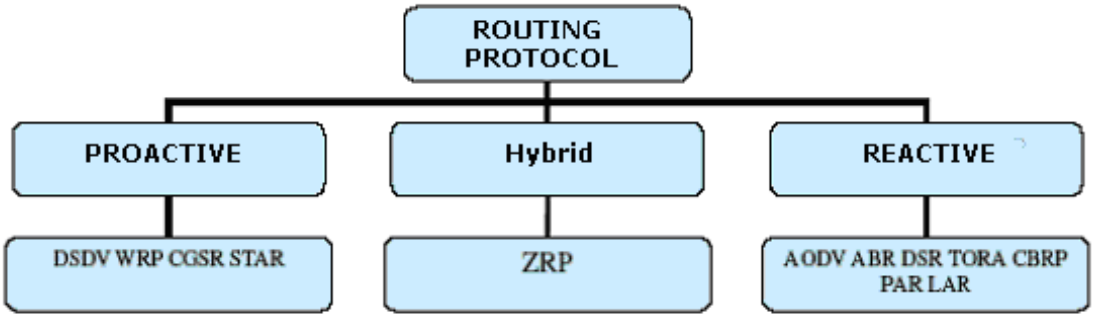

Figure 1.3 Categorization of adhoc routing protocols

(5) Unidirectional link supports Due to variances in wireless radio range between devices, routes may not be bi-directional. This needs to be factored into protocol design so that an alternative route can be used for the return path.As mentioned, ad-hoc network routing protocols fall into two categories: - Demand driven (reactive) protocols or Table-driven (proactive) protocols. Proactive protocols seek to reduce node discovery latency. These protocols require each node to maintain up-to-date routing tables containing routing information from each node to every other node in the network. They respond to changes in network topology by propagating route updates throughout the network to maintain a consistent network view. The areas in which the various protocols differ are the number of necessary routing-related tables and the methods by which changes in the network structure are broadcast. In 2.1 the operation of the proactive protocol, DSDV (Destination Sequenced Distance Vector routing), is outlined. Demand-based (Reactive) protocols seek to reduce control overhead and link usage by constructing routing information only when the source node requires a route. These savings are gained at a cost of increased route discovery relay. A source node looking for a route to a destination initiates a route discovery within the network. This process is completed once a route is found or all possible route permutations have been examined. Once a route has been discovered and established, some form of route maintenance procedure maintains it until either the destination becomes inaccessible along every path from the source or the route is no longer desired. In 2.2 the operation of the reactive protocol AODV (Ad Hoc On Demand Distance Vector routing) is outlined.

1.3 DSDV Protocol Outlined

Destination Sequenced Distance Vector routing is a table-driven routing protocol based on the Bellman-Ford algorithm. The modification for ad-hoc networks is that routing loops are avoided. Each network node maintains its own routing table in which all destination nodes in the network and the numbers of routing hops are recorded. Routing information is always available, whether a route is required or not by a source node. Routes are given a sequence number to distinguish stale routes from new ones. Routing table updates are sent periodically throughout the network to maintain consistency. To reduce the amount of network traffic that this produces, table updates are sent as smaller incremental updates during periods of low mobility. During periods of high mobility, full table updates are distributed. As new routes are added to the tables, they include the destination node address and the number of hops. The route with the most recent sequence number (indicating freshness) is always used. If two routes have the same sequence number then the one with the smaller hop count is used.

1.4 AODV Protocol Outlined

The Ad Hoc On-Demand Distance Vector (AODV) builds on the DSDV protocol by minimizing the required number of broadcasts by creating routes on a source initiated, on-demand basis. There is no requirement to maintain a complete list of routes. When a source node wants to communicate with a destination node, it broadcasts (multicasts, if IPv6 is being used) a route request (RREQ) packet to its neighbors. They will forward it on to their neighbors and so on, until it reaches a node with a fresh route to the destination or the destination itself.

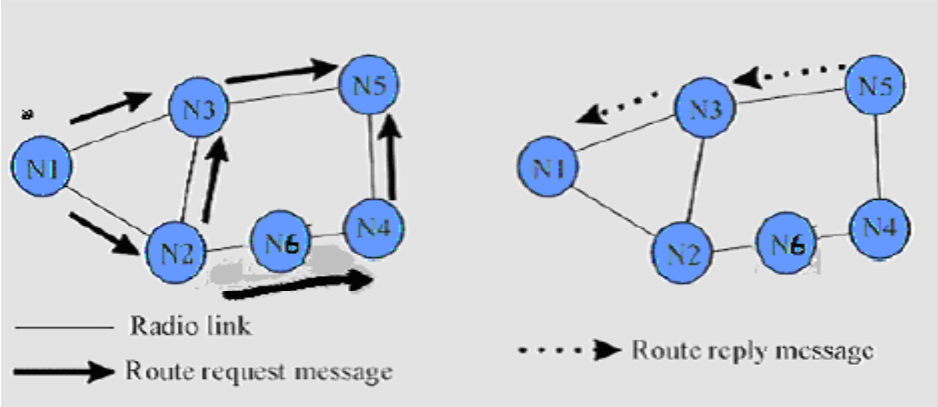

Figure 1.4 AODV/DSR route discovery, route request message is broadcast,route reply message is unicast

AODV uses sequence numbers to indicate route freshness and to avoid route loops. During the forwarding of RREQ packets the intermediate nodes record in their cached route tables the address of the neighbor from whom they received the RREQ, thereby establishing a reverse path. The destination node or intermediate node with a fresh route to the destination, responds by unicasting a route reply (RREP) package to the source along the reverse path. (Note: Because of this AODV has the limitation of only supporting routes over bi-directional links, routes over uni-directional links will fail). Mobility of nodes may break a previously established route. An upstream node detects this and a link failure notification is sent to each of its active upstream neighbors until the source is reached which may initiate a new route request if require.

1.5 Securities in Mobile Ad-Hoc Networks

When discussing network security in general, two aspects need to be considered; the services required and the potential attacks. The security services aspect includes the functionality that is required to provide a secure networking environment while the security attacks cover the methods that could be employed to break these security services.

1.5.1 Network Security Goals

In providing a secure networking environment some or all of the following services may be required:

Confidentiality Ensures that the intended receivers can only access transmitted data. This is generally provided by encryption. Two types of encryption are commonly used (a detailed description of these is outside the scope of this report).Symmetric Encryption, where 2 nodes share a key (e.g. - DES, AES). Any data transmitted between the nodes is encrypted using this key. This key must be provided to the nodes over a secure channel. Symmetric encryption generally requires less computational resources than public key encryption. Public Key Encryption, where all nodes participating generate a public\private key pair pubKn/privKn. The node makes its public key pubKn available to all nodes. If other nodes wish to send data to node *n*, they encrypt their data using pubKn, safe In the knowledge that it can only be decrypted by *n*'s private key privKn, which only node n knows.

Integrity Ensures that the data has not been altered during transmission. The integrity service can be provided using cryptographic hash functions along with some form of encryption. When dealing with network security the integrity service is often provided implicitly by the authentication service.

Authentication Both sender and receiver of data need to be sure of each other's identity. Authentication can be provided using encryption along with cryptographic hash functions, digital signatures and certificates. Details of the construction and operation of digital signatures can be found in RFC2560.

Non-repudiation Ensures that parties can prove the transmission or reception of information by another party, i.e. a party cannot falsely deny having received or sent certain data. Non-repudiation requires the use of public key cryptography to provide digital signatures. A trusted third party is required to provide a digital signature.

Availability Ensures that the intended network security services listed above are available to the intended parties when required. The availability is typically ensured by redundancy, physical protection and other non-cryptographic means, e.g. use of robust protocols.

This is a vague metric and is provided in varying degrees by all security protocols. There are various types of threats or attacks networks can be vulnerable to, some of which are listed below:

1.5.2 Attacks

Eavesdropping This attack is used to gain knowledge of the transmitted data. This is a passive attack, which is easily performed, in many networking environments. However using an encryption scheme to protect the transmitted data can prevent this attack.

Impersonation Here the attacker uses the identity of another node to gain unauthorized access to a resource or data. This attack is often used as a prere qui site to eavesdropping. By impersonating a legitimate node the attacker can try to gain access to the encryption key used to protect the transmitted data. Once the attacker knows this key, she can successfully perform the eavesdropping attack.

Modification This attack modifies data during the transmission between the communicating nodes, implying that the communicating nodes do not share the same view of the transmitted data. An example could be when the transmitted data represents a financial transaction where the attacker has modified the transactions value.

Replay The attacker retransmits data previously transmitted by a legitimate node.

Denial of Service (DoS) This active attack aims at obstructing or limiting access to a certain resource.

This resource could be a specific node or service or the whole network. This will affect the availability security service mentioned above. The nature of ad-hoc networks where several routes exist between nodes and routes are very dynamic gives ad-hoc a built-in resistance to DoS attacks, compared to fixed networks. Security mechanisms

for wireless ad-hoc networks should aim to provide all the security services listed above and prevent any of the attacks mentioned. However, due to the lack of infrastructure in an ad-hoc wireless network, typical wired-network implementations of the methods mentioned above may not be possible. Along with the general issues listed above, there are also other specific key issues and challenges for providing security in ad-hoc.

Link Level Security In wireless environment the links are susceptible to attacks where eavesdropper can intercept data packets. Physical barriers such as walls\rooms\&c. provide no barrier to wireless radio packets.

Routing\Network layer Security The routing within ad hoc networks is more vulnerable to attack as each device itself acts as a router. An attacker can pose as a member node and incorrectly route packets to achieve an attack. Denials of service attacks are particularly easy doing this. Thus implementation of secure routing protocol is one of the challenges within ad hoc network. The use of IPSec to provide authentication, confidentiality and integrity is discussed in this report. By securing all IP traffic (or whatever network layer protocol is used), you are also securing outing.

Key Management General network security implementation of keys involves a trusted authority.

Given the lack of infrastructure in ad-hoc, it is generally not possible to have a fixed trusted authority. An alternative to this is required. Security mechanisms will now be outlined for the 802.11 protocols and the Bluetooth protocol.

CHAPTER 2

LITERATURE REVIEW

2.1 Detection And Prevention Of Attacks On Manets Using Advanced Eaack And Hybrid Key Cryptography

Sharad Awatade, Pankaj Chandre, International Journal of Advanced Computational Engineering and Networking, ISSN: 2320-2106, Volume-4, Issue-1, Jan.-2016

2.1.1 Introduction

MANET having decentralized architecture in which all the node communicating in wireless manner. Thus, to increase the scalability of network there is need all node properly work together. MANETs are self-forming, self –maintained and Self-configuring allowing extreme network Scalability, & flexibility, which is often used in military conflict and medical emergency recovery. it oprets on single hop network and multihope network. Mantes is useful in emergency requirements where network range not possible and difficult to install network. Because it supports easy deployment, low cost, faster speed. MANETS having distributed architecture therefore providing security to MANETS is very difficult**.** In this paper, we aim to develop such an efficient and reliable intrusion detection system (IDS). Elliptic Curve Cryptography (ECC) algorithm is used to provide security to the data that is sent between the nodes. to reduce network overhead caused by digital signature Hybrid key cryptography technique is used.

2.1.2 Result

In this paper we study different attacks on Mantes Such as Gray hole Attack Man in Middle attack, wormhole Attack, HTTP GET Food Attack. For preventing these attacks we use RSA, DSA, RC6, Blowfish algorithm, Twoflish algorithm. First watchdog use for IDS for MANETs. But There are lots of disadvantages or drawbacks for removing these drawbacks we use EAACK algorithm .For preventing attack first we use

RSA and DSA algorithm. for reducing network overhead which is caused by digital signature we use hybrid cryptosystem.

2.1.3 **Drawbacks**

- Ambiguous collision
- Receiver collision
- Not able to implement clustering

2.2 A Survey on Secure Intrusion Detection System for MANET

Ms Priyanka P Kulkarni, International Journal of Advanced Research in Computer Science and Software Engineering, Volume 5, Issue 1, January 2015 ISSN: 2277 128X

2.2.1 Introduction

MANET (Mobile Ad hoc network) is an IEEE 802.11 framework which is a collection of mobile nodes equipped with both a wireless transmitter and receiver communicating via each other using bidirectional wireless links. This type of peer to peer system infers that each node or user in the network can act as a data endpoint or intermediate repeater. Thus, all users work together to improve the reliability of network communications. MANETs are self-forming, self maintained and self-healing allowing for extreme network flexibility, which is often used in critical mission applications like military conflict or emergency recovery. Minimal configuration and quick deployment make MANET ready to be used in emergency circumstances.. Due to MANET's distributed architecture and changing topology, a traditional centralized monitoring technique is no longer feasible in MANETs. Hence, it is crucial to develop an intrusion detection system in MANETs. In this paper, we aim to develop such an efficient and reliable intrusion detection system (IDS).

2.2.2 Result

In this research paper, we have study a novel INTRUSION-DETECTION SYSTEM named EAACK protocol specially designed for MOBILE AD-HOC NETWORKs and compared it against other popular mechanisms in different scenarios through simulations. The demonstrated positive performances against Watchdog, TWOACK, and AACK.We also surveyed some intrusion detection systems that deals with various attacks. Attacker may find some new way to attack the system. Therefore system need to much robust so that it prevents new vulnerabilities and themselves. It is important to develop network security policies and deploy into MANET, this can be good research area. There should be system that learns from the knowledge of previous attacks and able to infer and detect new attacks; this can be potential research area.

2.2.3 Drawback

- Limited transmission power

2.3 Design of EAACK Protocol for Partial Dropping in Watchdog Security Scheme

S.Sri Gowthem, K.P. Kaliyamurthie, International Journal of Innovative Research in Computer and Communication Engineering (An ISO 3297: 2007 Certified Organization) Vol. 3, Issue 9, September 2015

2.3.1 Introduction

Mobile Ad hoc NETwork (MANET) is a collection of mobile nodes equipped with both a wireless transmitter and a receiver that communicate with each other via bidirectional wireless links either directly or indirectly. Industrial remote access and control via wireless networks are becoming more and more popular these days. One of the major advantages of wireless networks is its ability to allow data communication between different parties and still maintain their mobility. MANET solves this problem by allowing intermediate parties to relay data transmissions. This is achieved by dividing MANET into two types of networks, namely, single-hop and multihop. MANET is capable of creating a self-configuring and self maintaining network without the help of a centralized

infrastructure, which is often infeasible in critical mission applications like military conflict or emergency recovery. Minimal configuration and quick deployment make MANET ready to be used in emergency circumstances where an infrastructure is unavailable or unfeasible to install in scenarios like natural or human-induced disasters, military conflicts, and medical emergency situations.

2.3.2 Result

Packet-dropping attack has always been a major threat to the security in MANETs. In this research paper, we have proposed a novel IDS named EAACK protocol specially designed for MANETs and compared it against other popular mechanisms in different scenarios through simulations. The results demonstrated positive performances against Watchdog, TWOACK, and AACK in the cases of receiver collision, limited transmission power, and false misbehavior report. Furthermore, in an effort to prevent the attackers from initiating forged acknowledgment attacks, we extended our research to incorporate digital signature in our proposed scheme. Although it generates more ROs in some cases, as demonstrated in our experiment, it can vastly improve the network's PDR when the attackers are smart enough to forge acknowledgment packets.We think that this tradeoff is worthwhile when network security is the top priority. In order to seek the optimal DSAs in MANETs, we implemented both DSA and RSA schemes in our simulation. Eventually, we arrived to the conclusion that the DSA scheme is more suitable to be implemented in MANETs.

2.3.3 Drawback

- Ambiguous collisions

2.4 A Comparative Study of EAACK Based Security Mechanism for MANETs

Brijal J. Patel1, Krunal Panchal, A Comparative Study of EAACK Based Security Mechanism for MANETs, Vol-2 Issue-6 2016 IJARIIE-ISSN(O)-2395-4396

2.4.1 Introduction

A mobile ad hoc network (MANET) is a one of the wireless method. The device are moving in randomly different directions and communicating with one to other within each nodes communication range. To extend the nodes communication range , the other nodes in the network act as router. MANET is a collection of mobile nodes equipped with both a wireless transmitter and a receiver that communicate with each other via bidirectional wireless links either directly or indirectly. One of the major advantages of wireless networks is its ability to allow data communication between different parties and still maintain their mobility. However, this communication is limited to the range of transmitters. This means that two nodes cannot communicate with each other when the distance between the two nodes is beyond the communication range of their own. MANET solves this problem by allowing intermediate parties to relay data transmissions. This is achieved by dividing MANET into two types of networks, namely, single-hop and multihop.

2.4.2 Result

In this paper, EAACK and IDS system for prevent and detect malicious attacks. Watch dog has a total of six weaknesses such as ambiguous collisions, receiver collisions, limited transmission power, false misbehavior report, collusion, and partial dropping in which three are handled with this system such as receiver collisions, limited transmission power, false misbehavior report. This gives an optimal solution for EAACK scheme and to reduce the network overhead in the case of authentication. Clustering routing algorithm provide security which find the secure routing and also provides some cryptography algorithms. In future work to solve other attacks and also work on security with energy efficient scheme for MANETs.

2.4.3 Drawbacks

- Ambiguous collisions
- Receiver collisions

2.5 Performance Enhancement of Intrusion Detection System Using Advance Adaptive EAACK for MANETs

Shraddha Kamble1, Dr.B.K Mishra2, Dr.Rajesh Bansode, International Journal of Computational Engineering Research (IJCER), ISSN (e): 2250 – 3005 || Volume, 06 || Issue, 06|| June – 2016

2.5.1 Introduction

A mobile ad hoc network (MANET) is a self-organizing and self-configuring multi-hop wireless network, where the nodes are free to move randomly. Ad hoc wireless network are self-creating and self-organizing. One advantage of wireless networks is the ability to transmit data among users in a local area while remaining mobile. The communication between the nodes is limited to their range of transmitter. This means that two nodes cannot communicate with each other when the distance between the two nodes is beyond the communication range of their own. MANET solves this problem they allow intermediate node to transmit data between two other nodes. To achieve this by MANETs are divided into two types into two types of networks, namely, single-hop and multi-hop. In a single-hop network, all nodes within the same radio range communicate directly with each other. On the other hand, in a multi-hop network, nodes rely on other intermediate nodes to transmit if the destination node is out of their radio range. In contrary to the traditional wireless network, MANET has no fix structure; thus, all nodes are free to move randomly. Moreover due to distributed nature of market centralized monitoring system is not feasible. In such case, it is crucial to develop an intrusion-detection system (IDS) specially designed for MANET

2.5.2 Result

In this paper the main focus has been laid on comparative study of EAACK approach and its limitation with EAACK protocol using advance EAACK. Here we have study the behavior of EAACK technique. SACK & MRA scheme but in scenario of link breakage and source maliciousness performance of existing EAACK degrades so the proposed protocol advance EAACK is compared against popular mechanism such as

TWOACK,AACK and EAACK in different scenario through simulation. Simulation parameters that are considered in this paper is packet delivery ratio and delay. The results demonstrated positive performances against TWOACK, AACK and EAACK in the cases of link breakage and source maliciousness.

2.5.3 Drawbacks

- Delay
- Link breakage
- Source maliciousness

2.6 Acknowledgement Based Intrusion Detection System in Mobile Ad-Hoc Networks using EAACK

Ms. Pallavi N. Ratnaparkhi, Mr. Ravindra D. Kale, International Journal of Engineering Research & Technology (IJERT), ISSN: 2278-0181, Vol. 3 Issue 4, April – 2014

2.6.1 Introduction

A Mobile Ad-hoc NETwork (MANET) is an infrastructure-less network consisting of self- configuring mobile nodes connected by wireless links 10. Nodes rely on each other to store and forward packets. The self-configuring ability of nodes in MANET made it popular among critical mission applications like military use or emergency recovery, network security is of vital importance. In this case, it is crucial to develop efficient intrusiondetection mechanisms to protect MANET from attacks. This technique for intrusion-detection will be used to enhance the proposed system performance merits by reducing the power consumption, reduced network delays and improved efficiency in MANETs with secure and authentic data transmission using more efficient hybrid cryptography techniques.

2.6.2 Result

In this paper we have studied the various IDS techniques that are used in MANETs to trap the intruders in the network. From this study it is conclude that packet-dropping attack has always been a major threat to the security in MANETs. The functions of such intrusion detection schemes all largely depend on the acknowledgment packets. Hence, the proposed IDS may guarantee that

- The acknowledgement packets are valid and authentic with more secure data packet transmission.
- The proposed IDS system will reduce the energy consumption and delays in network with less routing overhead during data packet transmission and also enhance the efficiency of MANETs.

2.6.3 Drawbacks

- False misbehavior result
- Partial droping

2.7 An Improvised Intrusion Detection System for MANETs

R.Gowtham, Celeste Fatima, R.G.Gopeeka, A.Chandrasekar, International Journal of Advanced Research in Computer Engineering & Technology (IJARCET) Volume 3 Issue 5, May 2014

2.7.1 Introduction

MANET is a collection of mobile nodes equipped with both a wireless-transmitter and receiver that correspond with each other via bi- directional wireless links either directly or indirectly. Industrial remote access and control via wireless network becoming more and more popular these days. One of the key advantages of wireless networks is its ability to allow data communication between different parties and still maintain their mobility. MANET has a decentralized network infrastructure. Attack prevention measures, such as validation and encryption, can be used as the first line of

defence for reducing the possibilities of attacks. However, these techniques have a restriction on the effects of prevention techniques in general and they are designed for a set of known attacks. They are unlikely to prevent newer attacks that are designed for circumventing the existing security measures. In this paper we are implementing the method of digital signature with multiple key generation schemes to enhance security by dividing the key into slots and sending it to the receiver.

2.7.2 Result

Mobile Ad Hoc Network has always been prone to security attacks. Since the existing methods concentrate only on detecting the malicious nodes we are not aware of the validity of the acknowledgement packets on which we fully rely on. So to ensure to validate the acknowledgement packets we digitally sign the keys and transmit the keys. We also implement a method of generating multiple key by dividing keys into slots. This leads to maximum network security for the present scenario without the loss of network performance.

2.7.3 Drawbacks

- Limited transmission power
- Collision

2.8 Secure EAACK to detect DoS Attacks in MANET

R.Anandakumar, Avinash Premanath, Fadle Ahmed, International Journal of Science, Engineering and Technology Research (IJSETR), Volume 3, Issue 4, April 2014

2.8.1 Introduction

Wireless Adhoc Network

A wireless ad hoc network is a decentralized type of wireless network. The network is adhoc because it does not rely on a pre existing infrastructure, such as routers in wired networks or access points in managed (infrastructure) wireless networks.

Instead, each node participates in routing by forwarding data for other nodes, so the determination of which nodes forward data is made dynamically on the basis of network connectivity. In addition to the classic routing, ad hoc networks can use flooding for forwarding data.

Mobile Adhoc Network (Manet)

A mobile ad hoc network is a self-configuring infrastructure less network of mobile devices connected by wireless. Each device in a MANET is free to move independently in any direction, and will therefore change its links to other devices frequently. Each must forward traffic unrelated to its own use, and therefore be a router. The primary challenge in building a MANET is equipping each device to continuously maintain the information required to properly route traffic. Such networks may operate by themselves or may be connected to the larger Internet.

2.8.2 Result

Packet-dropping attack has always been a major threat to the security in MANETs. EAACK protocol is specially designed for MANETs which outperforms Watchdog, TWOACK, and AACK in the cases of receiver collision, limited transmission power, and false misbehavior report. Using AES – Rijndael and RSA algorithm as a hybrid encryption scheme we can improve confidentiality, availability and integrity of the system. So our proposed system ensures more security to the network and also improves throughput.

2.8.3 Drawback

- Error will occur

2.9 An Enhanced Intrusion detection system for MANETS using Hybrid key cryptography

B.Suruthi1 Mr.N.V.Rajeesh kumar, International Journal of Computer Science and Information Technologies, Vol. 5 (2), 2014, 1152-1154

2.9.1 Introduction

MANETS are wireless networks, and decentralised and no fixed topology. Each node in network act both as transmitter and receiver. Nodes communicate with each other either directly or indirectly (with the help of their neighbors).Hence this is possible by single hop network and Multi-hop networks. In Single-hop network, all the nodes within the same radio range communicate with each other. In Multi-hop network, nodes depend on neighbors to transmit if destination node is out of their radio range. MANET is highly vulnerable to attacks because, node configuration and maintenance are done on its own. Then Enhanced Adaptive ACKnowledgement scheme is used to overcome the disadvantage of false misbehaviour report. MANET are mostly preferred for military, areas that include natural disaster, medical emergency.

2.9.2 Result

The newly proposed scheme called EAACK, and it provides better performances comparing to all other existing approaches. The EAACK scheme implements digital signature which causes network overhead which can be further reduced by hybrid key cryptography. This cryptography technique uses RSA, AES for providing security and Zone Routing Protocol (ZRP) to find the route between source and destination.

2.9.3 Drawback

- Implementation is difficult.

2.10 Extended EAACK- An secure intrusion detection system with detection and localization of multiple spoofing attackers in MANET

Aditya P. Tapaswi, Pratik P. Nashikkar, Rohit S. Barge, Aniket M. Shinde, Prof. Pramod Patil, International Journal of Scientific and Research Publications, Volume 4, Issue 12, December 2014

2.10.1 Introduction

With constantly changing technology, people prefer to have information on their fingertips anywhere - anytime Thus increasing in the use of wireless networks. MANET one of the promising technology in wireless networking has features like dynamic configurability, low cost of deployment. MANET does not need a fixed infrastructure. MANET is dynamically configurable network in which nodes set up paths among themselves to transmit packets. Without getting help of fixed infrastructure MANET forms self-configuring network by collection of mobile nodes. Transmitter and receivers both are equipped in a MANET node, so node can act as a Router and a Host at the same time. There are two scenarios concerning topology in MANET. Thus acting like a Router to relay mes-sages to other nodes outside each others range have to rely on some other nodes to relay messages.

2.10.2 Result

Packet Dropping and Identity based attacks have always been main threats to MANET. In this paper, we proposed a fully equipped system named E-EAACK primarily in-tended for MANET and made it efficient in comparison to other popular mechanisms. It also overcomes the issues in MANET such as limited transmission power, receivers collision and false misbehavior report. We also propose the use of RSS based spatial correlation associated with each node that is hard to falsify for detecting identity based attacks. Our system can do both, detect the attack and decide the number of invaders and exclude them.

2.10.3 Drawback

- Collision will occur

2.11 Summary of Literature Review

The summary of the literature review is given by table 2.1 it contains title of the paper, technique and its drawback.

Table 2.1 Summary of Literature Review

S.No	Title	Technology	Drawback
1.	Detection and prevention of attacks on Manets using advanced EAACK and hybrid key Cryptography	Adavnced Enhanced Adaptive Acknowledgment (EAACK) and Mobile Ad hoc Network (MANET)	Receiver collision Unable implement dynamic clustering Ambiguous collision
2.	A Survey on Secure Intrusion Detection System for MANET	ACK, EAACK and MANETs	Limited transmission power
3.	Design of EEACK Protocol for Partial Dropping in Watchdog Security Scheme	WATCHDOG,TWOACK,AACK,MRA used to implemented both DSA and RSA schemes in simulation	Ambiguous collision
4.	A Comparative Study of EAACK Based Security Mechanism for MANETs	Modified Enhanced Adaptive Acknowledgement (EAACK), Digital Signature, IDS.	Receiver collision Ambiguous collision
5.	Performance Enhancement of Intrusion Detection System Using Advance Adaptive EAACK for MANETs	Dynamic source routing (DSR) , Digital Signature Algorithm (DSA), Advanced EAACK (Enhanced Adaptive Acknowledgment)	Receiver collision

6.	Acknowledgement Based Intrusion Detection System in Mobile Ad-Hoc Networks using EAACK	Hybrid cryptograghy technique.	Ambiguous collision
7.	An Improvised Intrusion Detection System for MANETs – Defensive EAACK	Defensive Enhanced Adaptive ACKnowledgement and Multiple key generation mechanism.	False Misbehaviour Report Collision Partial Dropping
8.	Secure EAACK to detect DoS Attacks in MANET	EAACK,AES Rijndael algorithm,RSA,SHA-512	Receiver collision
9.	EAACK-Intrusion-Detection-System for MANETs	Efficient intrusion system (EAACK) for MANETs.	False Misbehaviour Report Ambiguous collision
10.	Extended EAACK-An secure intrusion detection system with detection and localization of multiple spoofing attackers in MANET	Watchdog; Extended Enhanced Adaptive Acknowledgement (E-EAACK); Digital Signature; IDS; Clustering	Limited transmission power

CHAPTER 3

THEORETICAL BACKGROUND

3.1 Existing Techniques

In traditional networks many intrusion detection systems have been proposed, the routers, gateways or switches are used for network traffic. Hence, it is easy to implement IDS in these networks. In MANETs we do not use such devices. Moreover, due to its openness so both malicious and legitimate users can access. In mobile environment it is very difficult to separate normal and unusual activities. Sometimes the false routing information can be generated by outdated node or from a malicious node due to the arbitrarily movement of nodes. Thus, the available intrusion detection techniques used in simple wired networks cannot be implemented to MANETs directly. Researchers have developed many intrusion detection systems for the MANETs. In the next section, we briefly explain three existing techniques, i.e. Watchdog, TWOACK, and (AACK).

3.2. Proposed System

The EEAACK system will consist of following techniques, model or mechanisms for intrusion detection and localization.

3.2.1 ACK

ACK is nothing but an end to end acknowledgment scheme. It acts as a crossbreed scheme in EEAACK. When there are no misbehaving nodes the transmission from source to destination is successful. Then destination sends an acknowledgement packet to source within predefined time constraint, otherwise source will switch to S-ACK mode.

3.2.2 S-ACK

Source sends S-ACK packet in the intention of detecting misbehaving nodes in the route. S-ACK sends acknowledgment back to source after the packet reaches consecutive three nodes ahead the route. The third node required to send a S-ACK acknowledgement to first node. S-ACK mode facilitates easy detection of misbehaving nodes in the presence of receiver collision and limited power for transmission.

3.2.3 MRA

Misbehaviour Report Analysis (MRA) is a scheme to confirm misbehaviour report generated in S-ACK mode. This report may be a false one as attacker may interfere in S-ACK scheme generating a false misbehaviour report. As a result, this may cause destruction of network by compromising guiltless nodes

3.3 Proposed Architecture

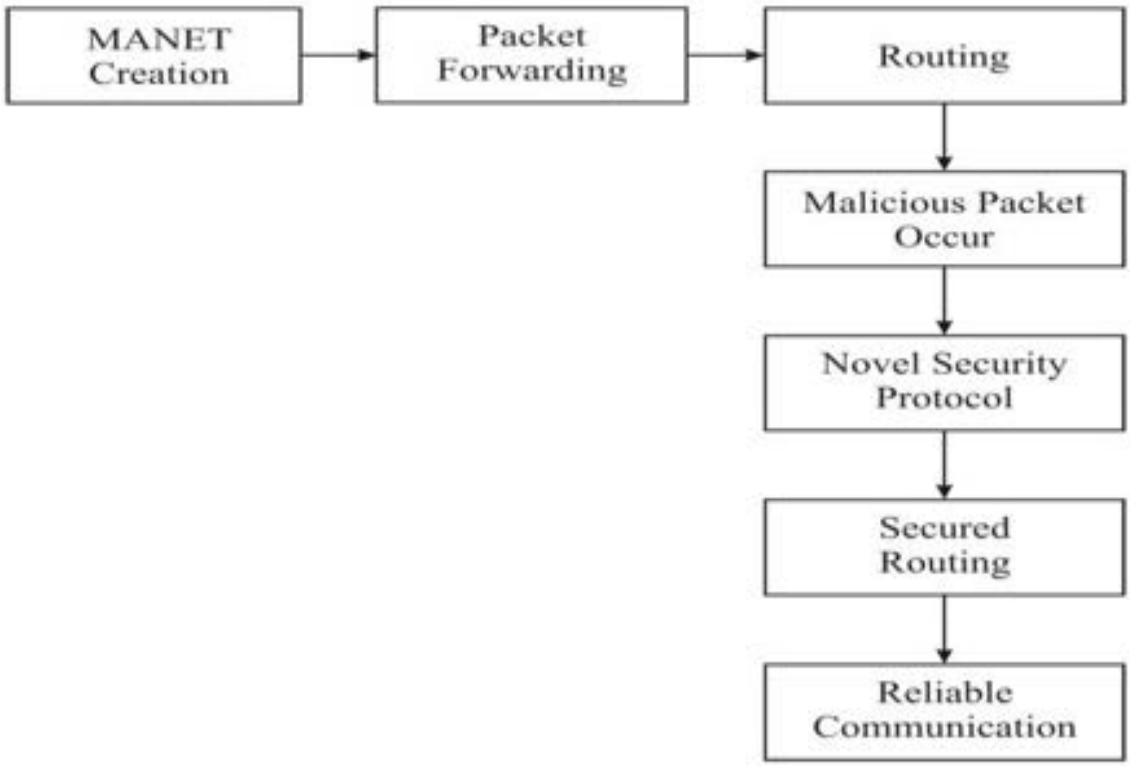

Figure 3.1 Proposed Architecture

CHAPTER 4

SYSTEM SPECIFICATION

4.1 Hardware Requirements

Processor : Dual core

Processor speed : 1.5 GHZ

Memory (RAM) : 2GB

Hard disk : 40GB

4.2 Software Requirements

Operating System : Linux 8.0(fedora 13)

Language : TCL Scripting

Software : ns2.33

4.3 Software Description

4.3.1 The Network Simulator 2.33 (Ns2)

Network Simulator (NS2) is a discrete event driven simulator developed at UC Berkeley. It is part of the VINT project. The goal of NS2 is to support networking research and education. It is suitable for designing new protocols, comparing different protocols and traffic evaluations. NS2 is developed as a collaborative environment. It is distributed freely and open source. A large amount of institutes and people in development and research use, maintain and develop NS2. This increases the confidence in it. Versions are available for FreeBSD, Linux, Solaris, Windows and Mac OS X.

4.3.2 Structure Of Ns2

NS2 is built using object oriented methods in C++ and OTcl (object oriented variant of Tcl) NS2 interprets the simulation scripts written in OTcl.

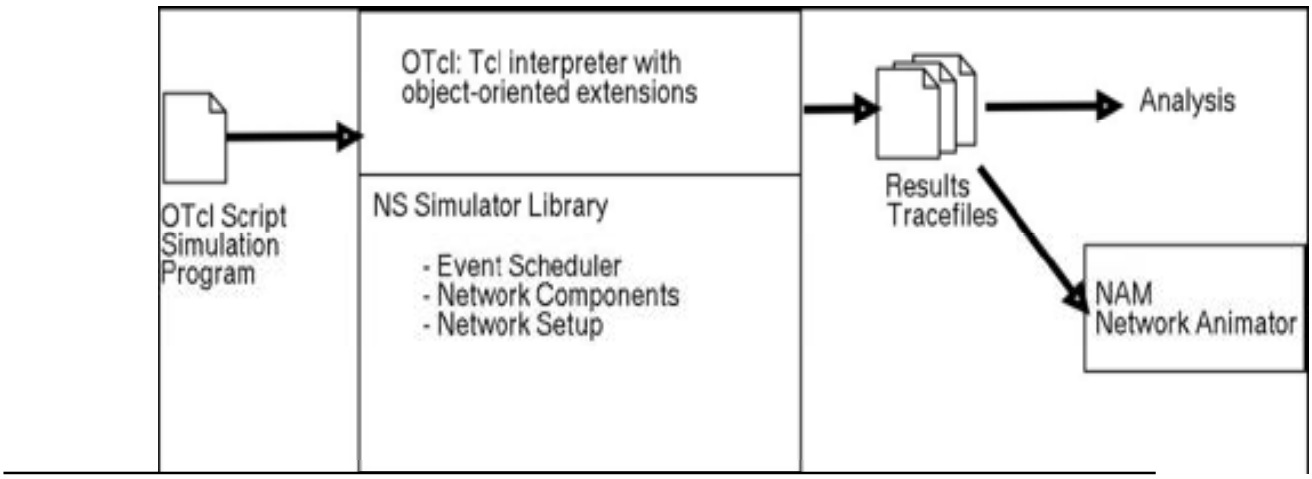

Figure 4.1 Simplified User's View Of Ns

A user has to set the different components (e.g. event scheduler objects, network components libraries and setup module libraries) up in the simulation environment. The user writes his simulation as a OTcl script, plumbs the network components together to the complete simulation. If he needs new network components, he is free to implement them and to set them up in his simulation as well. The event scheduler as the other major component besides network components triggers the events of the simulation (e.g. sends packets, starts and stops tracing). Some parts of NS2 are written in C++ for efficiency reasons. The data path (written in C++) is separated from the control path (written in OTcl). Data path object are compiled and then made available to the OTcl interpreter through an OTcl linkage (tclcl) which maps methods and member variables of the C++ object to methods and variables of the linked OTcl object. The C++ objects are controlled by OTcl objects. It is possible to add methods and member variables to a C++ linked OTcl object.

4.4 Functionalities Of Ns2.33

Functionalities for wired, wireless networks, tracing, and visualization are available in NS2.

• Support for the wired world include

– Routing DV, LS, and PIM-SM.

– Transport protocols: TCP and UDP for unicast and SRM for multicast.

– Traffic sources: web, ftp, telnet, cbr (constant bit rate), stochastic, real audio.

– Different types of Queues: drop-tail, RED, FQ, SFQ, DRR.

– Quality of Service: Integrated Services and Differentiated Services.

– Emulation.

• Support for the wireless world include

– Ad hoc routing with different protocols, e.g. AODV, DSR, DSDV, TORA

– Wired-cum-wireless networks

– Mobile IP

– Directed diffusion

– Satellite

– Senso-MAC

– Multiple propagation models (Free space, two-ray ground, shadowing)

– Energy models

• Tracing

• Visualization

– Network Animator (NAM)

– Trace Graph

• Utilities

– Mobile Movement Generator

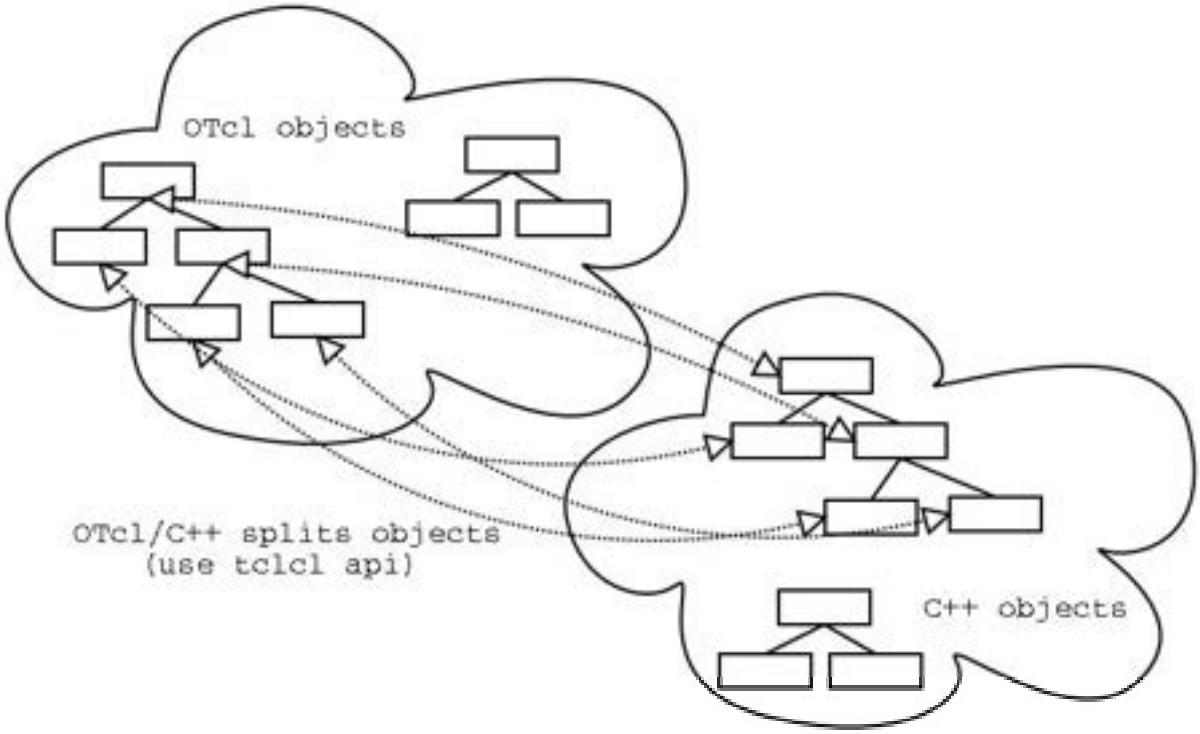

Figure 4.2 OTcl and C++: the duality

4.4.1 Mobile Networking In Ns2.33

This section describes the wireless model that was originally ported as CMU's Monarch group's mobility extension to NS2. The first section covers the original mobility model ported from CMU/Monarch group. In this section, we cover the internals of a mobile node, routing mechanisms and network components that are used to construct the network stack for a mobile node. The components that are covered briefly are Channel, Network interface, Radio propagation model, MAC protocols, Interface Queue, Link layer and Address resolution protocol model (ARP). CMU trace support and Generation of node

movement and traffic scenario files are also covered in this section. The original CMU model allows simulation of pure wireless LANs or multihop ad-hoc networks. Further extensions were made to this model to allow combined simulation of wired and wireless networks. MobileIP was also extended to the wireless model.

4.4.2 The Basic Wireless Model In Ns

The wireless model essentially consists of the MobileNode at the core, with additional supporting features that allows simulations of multi-hop ad-hoc networks, wireless LANs etc. The MobileNode object is a split object. The C++ class MobileNode is derived from parent class Node. A MobileNode thus is the basic Node object with added functionalities of a wireless and mobile node like ability to move within a given topology, ability to receive and transmit signals to and from a wireless channel etc. A major difference between them, though, is that a MobileNode is not connected by means of Links to other nodes or mobilenodes. In this section we shall describe the internals of MobileNode, its routing mechanisms, the routing protocols dsdv, aodv, tora and dsr, creation of network stack allowing channel access in MobileNode, brief description of each stack component, trace support and movement/traffic scenario generation for wireless simulations.

4.4.3 Mobile Node: Creating Wireless Topology

Mobile Node is the basic *ns* Node object with added functionalities like movement, ability to transmit and receive on a channel that allows it to be used to create mobile, wireless simulation environments. The class Mobile Node is derived from the base class Node. Mobile Node is a split object. The mobility features including node movement, periodic position updates, maintaining topology boundary etc are implemented in C++ while plumbing of network components within Mobile Node itself (like classifiers, dmux , LL, Mac, Channel etc) have been implemented in Otcl.

Table 4.1 Available Options For Node Configuration

Option	Available Values	Default
General		
Address type	Flat, Hierarchical	Flat
MPLS	ON,OFF	OFF
Both Satellite and Wireless Oriented		
Wired Routing	ON,OFF	OFF
II Type	LL,LL/sat	OFF
Mac Type	Mac/802_11,Mac/Csma/ Ca, Mac/Sat/Unslotted/Aloha ,Mac/Tdma	OFF

Errproc	UniformErrorProc	OFF

FECProc	?	?
ToraDebug	ON,OFF	OFF

Implementation Environment

Network simulator 2 is used as the simulation tool in this project. NS was chosen as the simulator partly because of the range of features it provides and partly because it has an open source code that can be modified and extended. There are different versions of NS and the latest version is ns-2.1b9a while ns-2.1b10 is under development

4.5 Network Simulator (Ns)

Network simulator (NS) is an object–oriented, discrete event simulator for networking research. NS provides substantial support for simulation of TCP, routing and multicast protocols over wired and wireless networks. The simulator is a result of an ongoing effort of research and developed. Even though there is a considerable confidence in NS, it is not a polished product yet and bugs are being discovered and corrected continuously.

NS is written in C++, with an OTcl1 interpreter as a command and configuration interface. The C++ part, which is fast to run but slower to change, is used for detailed protocol implementation. The OTcl part, on the other hand, which runs much slower but can be changed very fast quickly, is used for simulation configuration. One of the advantages of this split-language program approach is that it allows for fast generation of large scenarios. To simply use the simulator, it is sufficient to know OTcl. On the other hand, one disadvantage is that modifying and extending the simulator requires programming and debugging in both languages.

NS can simulate the following:

1. **Topology:** Wired, wireless
2. **Scheduling Algorithms:** RED, Drop Tail,
3. **Transport Protocols:** TCP, UDP

4. Routing: Static and dynamic routing

5. Application: FTP, HTTP, Telnet, Traffic generators

4.6 User's View Of Ns-2

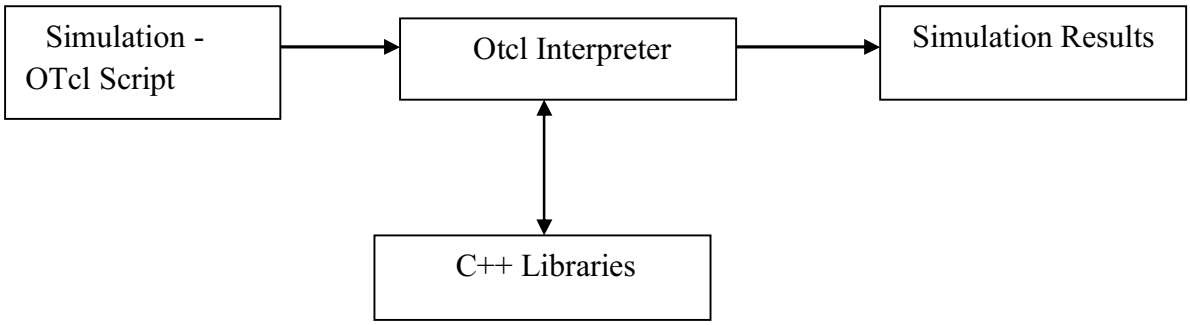

Figure 4.3 Block diagram of Architecture of NS-2

4.7 Network Components

This section talks about the NS components, mostly compound network components. Figure 4.2 shows a partial OTcl class hierarchy of NS, which will help understanding the basic network components.

The root of the hierarchy is the TclObject class that is the super class of all OTcl library objects (scheduler, network components, timers and the other objects including NAM related ones). As an ancestor class of TclObject, NsObject class is the super class of all basic network component objects that handle packets, which may compose compound network objects such as nodes and links. The basic network components are further divided into two subclasses, Connector and Classifier, based on the number of the possible output DATA paths.

The basic network and objects that have only one output DATA path are under the Connector class, and switching objects that have possible multiple output DATA paths are under the Classifier class.

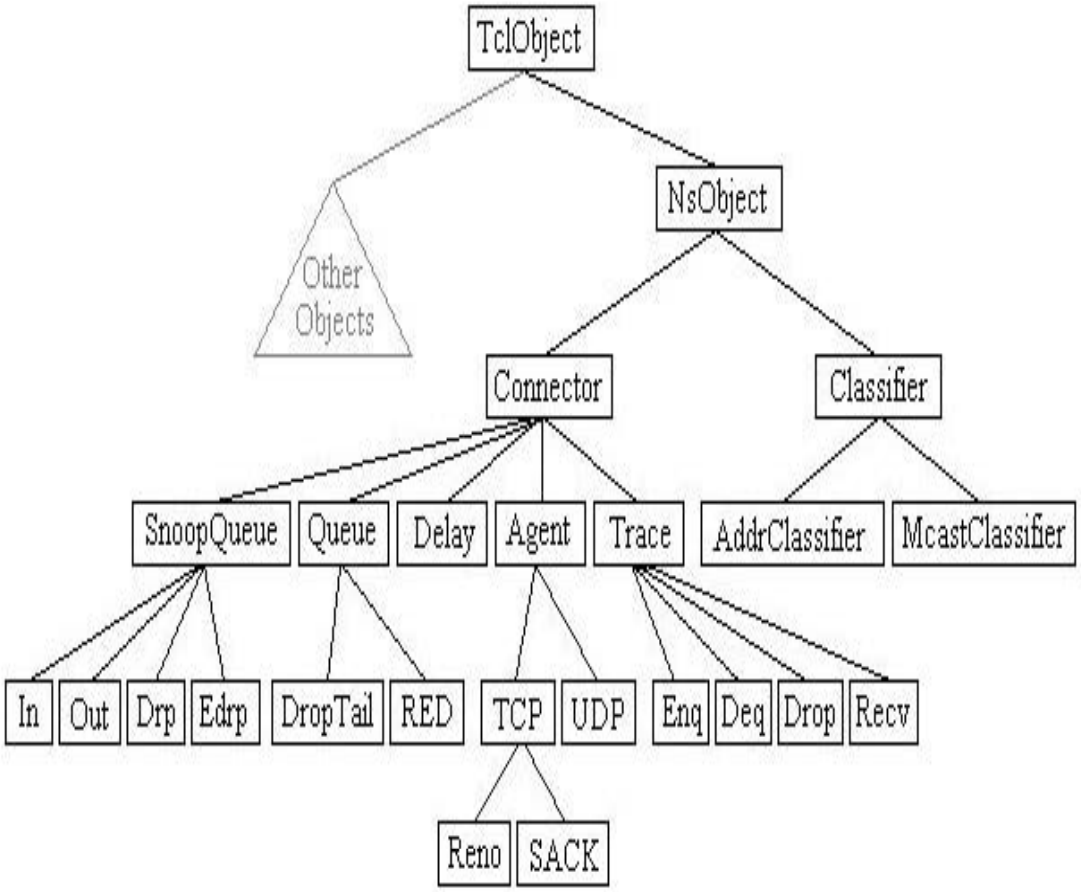

Figure 4.4 OTcl Class Hierarchy

4.8 Class Tcl

The class Tcl encapsulates the actual instance of the OTcl interpreter and provides the methods to access and communicate with that interpreter, code. The class provides methods for the following operations:

1.obtain a reference to the Tel instance

2.invoke OTcl procedures through the interpreter

3.retrieve, or pass back results to the interpreter

4.report error situations and exit in an uniform manner

5.store and lookup "TclObjects"

4.8.1 Obtain a Reference to the class Tcl instance

A single instance of the class is declared in -tclcl/Tcl.cc as a static member variable. The statement required to access this instance is Tel& tel = Tcl::instance();

4.8.2 Invoking OTcl Procedures

There are four different methods to invoke an OTcl command through the instance, tcl. They differ essentially in their calling arguments. Each function passes a string to the interpreter that then evaluates the string in a global context. These methods will return to the caller if the interpreter returns TCL_OK. On the other hand, if the interpreter returns TCL_ERROR, the methods will call tkerror{}. The user can overload this procedure to selectively disregard certain types of errors.

1. **Passing Results to/from the Interpreter :** When the interpreter invokes a C++ method, it expects the result back in the private member variable, tcl-> result.
2. **Error Reporting and Exit:** This method provides a uniform way to report errors in the compiled code.

4.9 Command Methods: Definition And Invocation

For every Tcl Object that is created, ns establishes the instance procedure, cmd{}, as a hook to executing methods through the compiled shadow object. The procedure cmd{} invokes the method command() of the shadow object automatically, passing the arguments to cmd{} as an argument vector to the command() method. The user can invoke the cmd {} method in one of two ways, by explicitly invoking the procedure, specifying the desired operation as the first argument, or implicitly, as if there were an instance procedure of the same name as the desired operation. Most simulation scripts will use the latter form.

Consider the distance computation in SRM is done by the compiled object. It is often used by the interpreted object. It is usually invoked as $srmObject distance? (agentAddress)If there is no instance procedure called distance? the interpreter

will invoke the instance procedure unknown{}, defined in the base class TclObject. The unknown procedure then invokes

$srmObject cmd distance? (agentAddress)

To execute the operation through the compiled object's command() procedure. The user could explicitly invoke the operation directly. One reason for this might be to overload the operation by using an instance procedure of the same name.

For example,

```
Agent/SRM/Adaptive instproc distance? addr {
$self instvar distanceCache_($addr)
if![info exists distanceCache_($addr)] {
set distanceCache_($addr) [$self cmd distance? $addr]
}
set distanceCache_($addr)
}
```

The following shows how the command() method using SRMAgent::command()

```
int ASRMAgent::command(int argc, const char*const*argv) {
Tcl& tcl = Tcl::instance();
if (argc == 3) {
if (strcmp(argv[1], "distance?") == 0) {
int sender = atoi(argv[2]);
SRMinfo* sp = get_state(sender);
tcl.tesultf("%f", sp->distance_);
return TCL_OK;  '
}
}
```

return (SRMAgent::command(argc, argv));

The following observations are made from this piece of code:

The function is called with two arguments. The first argument (argc) indicates the number of arguments specified in the command line to the interpreter. The command line arguments vector (argv) consists of argv[0] contains the name of the method, "cmd" and argv[1] specifies the desired operation. If the user specified any arguments, then they are placed in argv[2...(argc - 1)]. The arguments are passed as strings. They must be converted to the appropriate data type.If the operation is successfully matched, the match should return the result of the operation,command () itself must return either TCL_OK or TCL_ERROR to indicate success or failure as its return code. If matched in this method, it must invoke its parent's command method, and return the corresponding result. This permits the user to conceive of operations as having the same inheritance properties as instance procedures or compiled methods.In the event that this command method is defined for a class with multipleinheritance, one of two implementations can be chosen

1.Either they can invoke one of the parent's command method, and return the result of that invocation.
2.They can each of the parent's command methods in some sequence, and return the result of the first invocation that is successful. If none of them are successful, then they should return an error.

4.10 Mobile Networking In Ns

The wireless model essentially consists of the Mobile Node at the core with additional supporting features that allows simulations of multi-hop ad-hoc networks, wireless LANs etc. The Mobile Node object is a split object. The C++ class Mobile Node is derived from parent class Node. A Mobile Node thus is the basic Node object with added functionalities of a wireless and mobile node like ability to move within a given topology, ability to receive and transmit signals to and from a wireless channel etc. A major difference between them is that a mobile Node is not connected by means of Links to other nodes or mobile nodes.

Mobile Node is the basic nsNode object with added functionalities like movement, ability to transmit and receive on a channel that allows it to be used to create mobile, wireless simulation environments. The class Mobile Node is derived from the base class Node. The four ad-hoc routing protocols that are currently supported are, Dynamic Source Routing (DSR), Temporally ordered Routing Algorithm (TORA) and Adhoc On-demand Distance Vector (AODV).

The general structure for defining a mobile node in ns2 is described as follows:

$ns node-config -adhocRouting $opt (adhocRouting)

-IIType $opt (II)

-macType $opt (mac)

-ifqType $opt (ifq) -ifqLen $opt (ifqlen)

-antType $opt (ant)

-proplnstance [new $opt (prop) -phyType $opt (netif)

-channel [new $opt (chan)]

-topolnstance $topo

-wiredRouting OFF

-agentTrace ON

-routerTrace OFF

-macTrace OFF

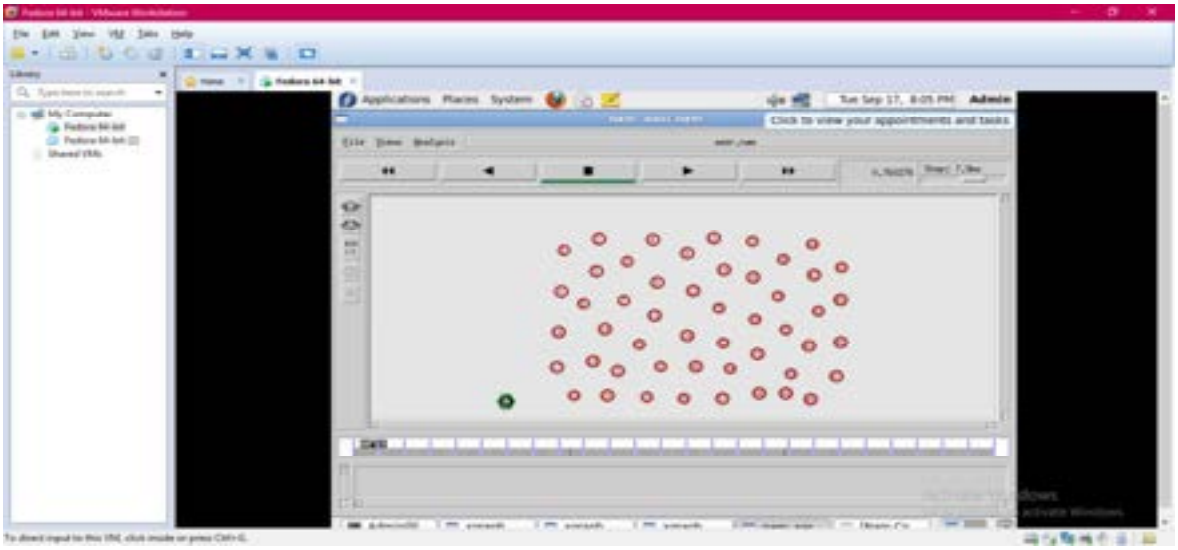
The above API configures for a mobile node with all the given values of ad hoc-routing protocol, network stack, channel, topography, propagation model, with wired routing turned on or off (required for wired-cum-wireless scenarios) and tracing turned on or off at different levels (router, mac, agent).

CHAPTER 5

SIMULATION RESULT

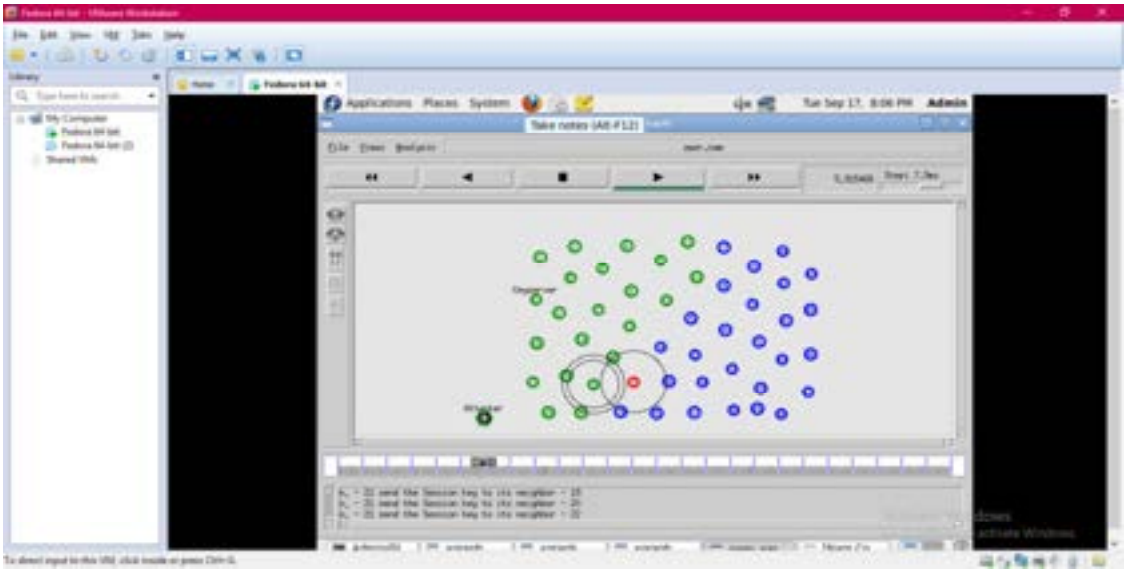
The simulation is conducted is with the Network Simulator (NS). The system is running on laptop with core 2 Duo t7250 CPU and 3GB RAM. The maximum hops allowed in this configuration setting are four. Both the physical layer and the 802.11 MAC layer are included in the wireless extension of NS2. The moving speed of mobile node is limited to 20m/s.

1. Declaring the nodes

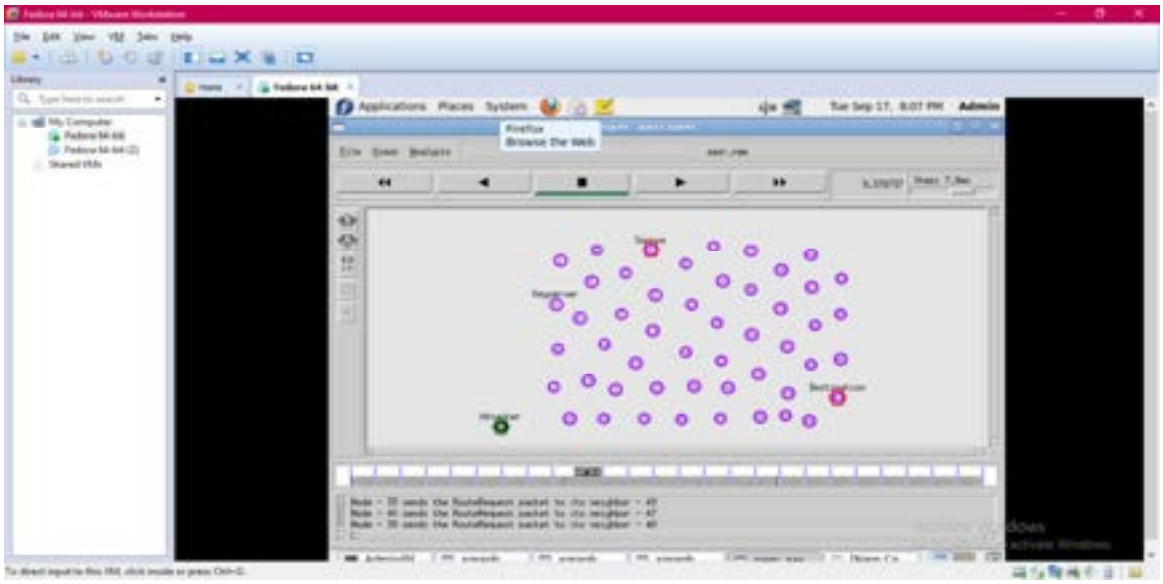


2. Broadcasting for finding the route for packet transmission.

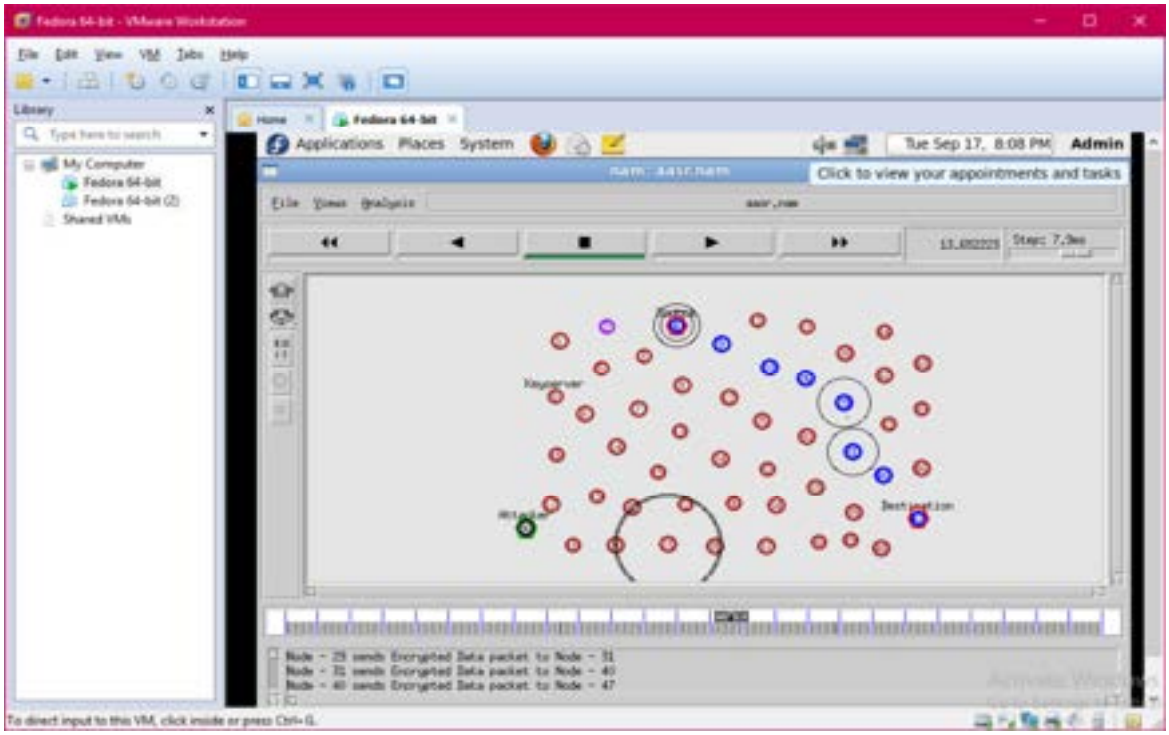
3. A path is chosen from source to destination.



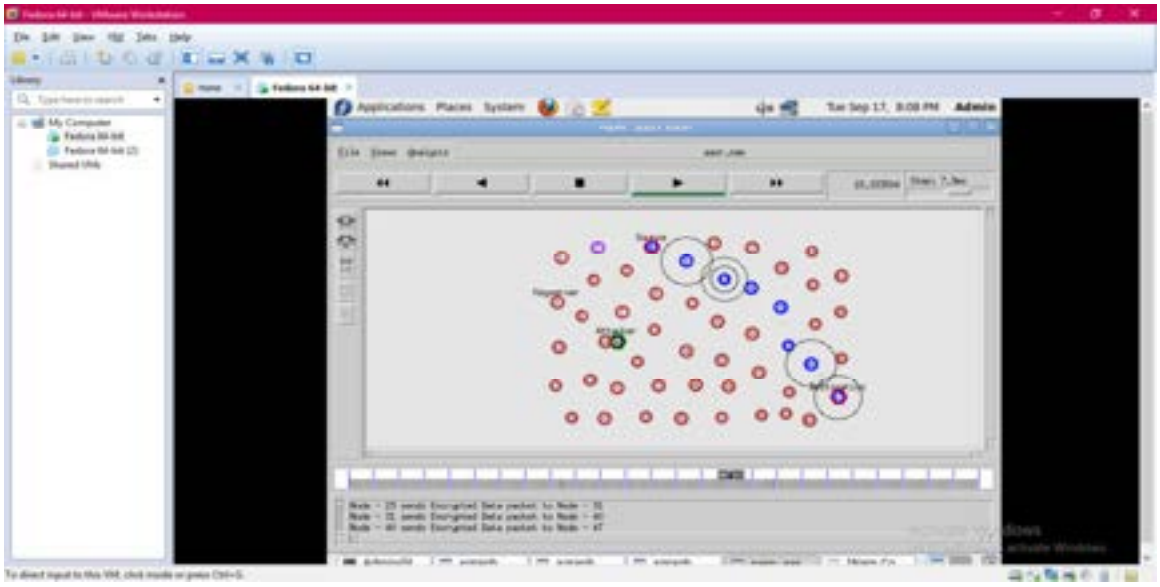
4. Declaring the source and destination nodes



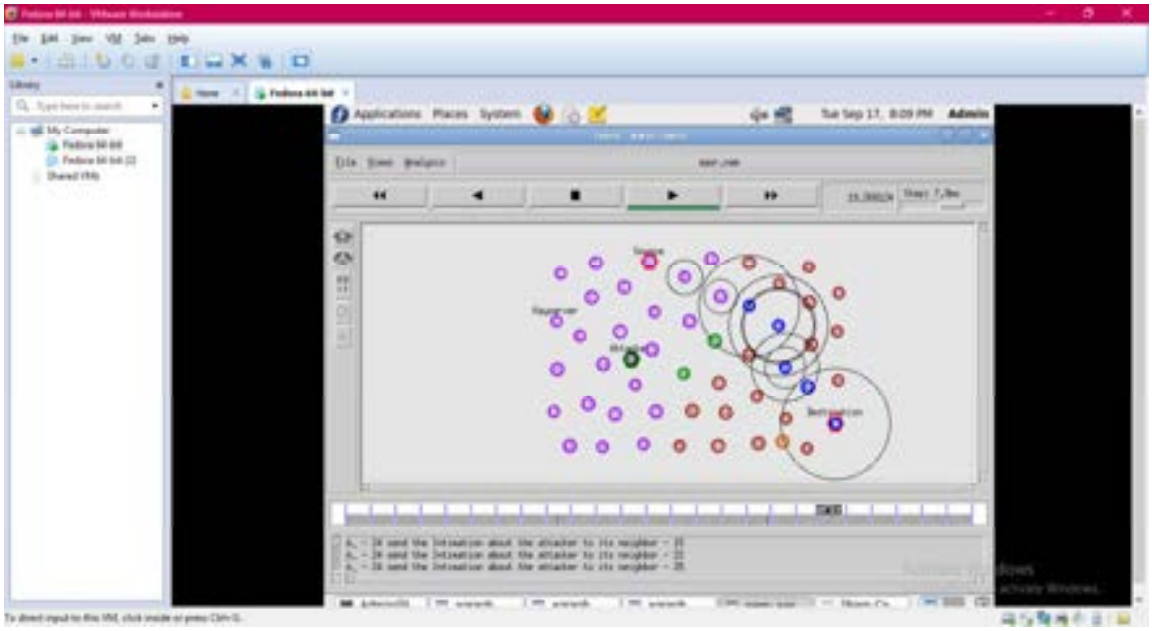
5. Searching the alternative path.



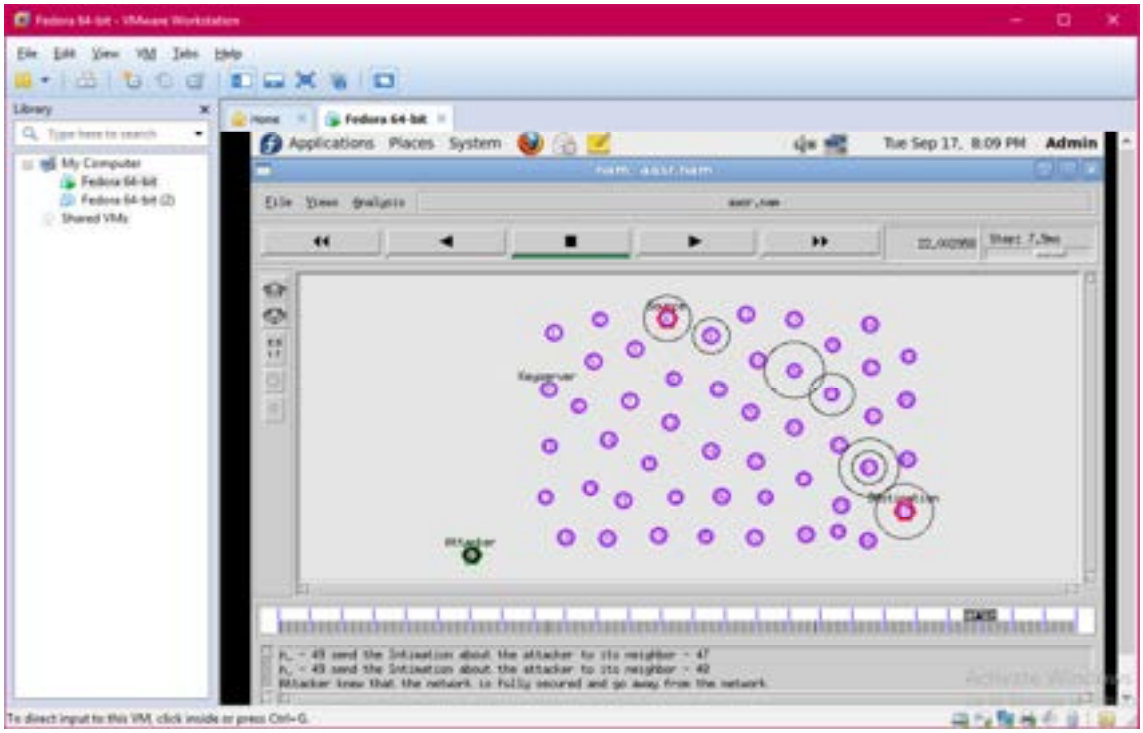
6. An alternative path is found.



7. A centralized node is formed for monitoring the nodes and the attacker nodes are detected in the current path so searching for an alternative path without malicious nodes.



8. The message was sent.



CHAPTER 6

CONCLUSION AND FUTURE ENHANCEMENT

6.1 Conclusion

To solve the security issue in MANETS we implemented new IDS based on enhanced adaptive Acknowledgment (EAACK). In this method every acknowledgment packet is digitally signed before sending in network and accepted only after verification. The limited transmission power and false misbehavior of nodes are completely removed in this scheme. Every acknowledgment packet received are authentic and untainted. This reduces the need for costly secure routing behaviors designed to mitigate the effects of an untrusted environment (and untrusted nodes) on the routing process. By preventing the entry of potentially untrustworthy nodes to the network, and thus the routing process, a MANET may be protected from subversion of its routing services at a lower cost, as malicious nodes are barred from the process entirely. This provides security to all data communicated over a MANET. It specifically targets the attributes of MANETs, it is not suitable for use in other types of network at this time. It sacrifices adaptability to a range of networks, to ensure that MANET communication is protected completely and efficiently. A single efficient method protects routing and application data, ensuring that the MANET provides reliable, confidential and trustworthy communication to all legitimate nodes.

6.2 Future Enhancement

This project can be extended further for many applications in real time environment. Further studies on improving the encryption technique is needed. it is time consuming process for reconstructing the message, which can be reduced further. The optimized routing techniques can be incorporated the finding shortest path.

ABSTRACT

Achieving reliable routing has always been a major issue in the design of communication networks, due to the absence of fixed infrastructure among which mobile ad hoc networks (MANETs) that can take control of the most adversarial networking environment, and the dynamic network topology the nature of open transmission media. In the MANETs these characteristics also more challenging to make the design of routing protocols. The network topology varies so to determining feasible routing paths for distributing messages in a decentralized is a difficult job. Factors such as the extensive distribution of nodes and open medium, variable wireless link quality topological changes, and propagation path loss become pertinent issues and make MANET unprotected to instructions. Thus, it becomes central to develop a systematic intrusion detection scheme to secure Mobile Ad Hoc networks from intruders. In this project, we put forward and applied an efficient IDS mechanism based on Enhanced Adaptive Acknowledgment (EAACK) especially made for MANETs which performs better than the earlier techniques such as AACK, TWOACK and Watchdog.

KEYWORDS: *Mobile Ad hoc Network (MANET), Acknowledgment (ACK), Network Simulator (NS2), Enhanced Adaptive Acknowledgement (EAACK), Misbehavior Report Authentication (MRA), Secure Acknowledgment (S-ACK), Digital Signature Algorithm (RSA)*

1. INTRODUCTION

Wireless networking is the need of hour for many applications because of its easier network expansion, increased mobility improved responsiveness, better access to information, and enhanced guest access. In addition, with the increasing standard of industry and use of lightweight network hardware devices that is even smaller and largely mobile. The wireless communication is enhanced by Mobile ad hoc networks (MANETs) having high degree of node mobility.

Mobile Ad hoc Network (MANETs):

The Wireless cellular system is used in 1980s. The Wireless systems operate with the help of a centralized supporting structure access point. The adaptability of wireless systems limits the presence of a fixed supporting structure. Also known as, in there is no fixed infrastructure the technology cannot work effectively. The Future generation requires the wireless systems easy and quick. In the current system this quick network deployment is not possible. There will be a need for the rapid deployment of independent mobile users for the next generation of the wireless communication systems. Significant examples include establishing efficient, survivable, military networks, dynamic communication for emergency/rescue operations and disaster relief efforts. This network scenarios cannot depend on centralized and organized connectivity, and can be conceived as applications of Mobile Ad Hoc Networks. The Mobile ad-hoc networks networks operate in the absence of fixed infrastructure. It is not possible otherwise in they offer quick and easy network deployment in situations where. The Ad-hoc is a Latin word, it means "for this only." The each node in the mobile ad hoc network is connected by wireless links; every node operates as an end system.

Mobile Ad Hoc Network Applications

The Mobile ad-hoc network (MANET) can be used in crisis situations like military conflicts, emergency medical situation, natural disasters etc.

2. Literature Review

2.1. Detection And Prevention of Attacks on Manets Using Advanced Eaack And Hybrid Key Cryptography

In this paper we study different attacks on Mantes Such as Gray hole Attack Man in Middle attack, wormhole Attack, HTTP GET Food Attack. MANET having decentralized architecture in which all the node communicating in wireless manner. Thus, to increase the scalability of network there is need all node properly work together. MANETs are self-forming, self –maintained and Self-configuring allowing extreme network Scalability, & flexibility, which is often used in military conflict and medical emergency recovery. it oprets on single hop network and multihope network. Mantes is useful in emergency requirements where network range not possible and difficult to install network. Because it supports easy deployment, low cost, faster speed.

MANETS having distributed architecture therefore providing security to MANETS is very difficult. MANETs are an attractive technology used diplomatic and risky or planned applications due to facility provided by MANET's infrastructure. But MANETS moves from security issue. Security is measure problem because it not having central point control, it support dynamic topology, and it having wireless medium. Hence, it is crucial to develop an intrusion detection system in MANETs. In this paper, we aim to develop such an efficient and reliable intrusion detection system (IDS). Elliptic Curve Cryptography (ECC) algorithm is used to provide security to the data that is sent between the nodes. to reduce network overhead caused by digital signature Hybrid key cryptography technique is used. The disadvantage are ambiguous collision occur and receiver collision.

2.2. A Survey on Secure Intrusion Detection System for MANET

MANET (Mobile Ad hoc network) is an IEEE 802.11 framework which is a collection of mobile nodes equipped with both a wireless transmitter and receiver communicating via each other using bidirectional wireless links. MANETs are self-forming, self maintained and self-healing allowing for extreme network flexibility, which is often used in critical mission applications like military conflict or emergency recovery. Unfortunately, the remote distribution and open medium of MANET makes them susceptible to various attacks. For example, due to lack of protection for nodes, malicious attackers can easily capture and compromise the mobile nodes to achieve attacks. Hence, it is crucial to develop an intrusion detection system in MANETs. In this paper, we aim to develop such an efficient and reliable intrusion detection system (IDS).

In this research paper, we have study a novel INTRUSION-DETECTION SYSTEM named EAACK protocol specially designed for MOBILE AD-HOC NETWORKs and compared it against other popular mechanisms in different scenarios through simulations. The demonstrated positive performances against Watchdog, TWOACK, and AACK. We also surveyed some intrusion detection systems that deals with various attacks. Attacker may find some new way to attack the system. Therefore system need to much robust so that it prevents new vulnerabilities and themselves. It is important to develop network security policies and deploy into MANET, this can be good research area. There should be system that learns from the knowledge of previous attacks and able to infer and detect new attacks; this can be potential research area. The drawback of this paper is limited transmission power.

2.3. Performance Enhancement of Intrusion Detection System Using Advance Adaptive EAACK for MANETs

A mobile ad hoc network (MANET) is a self-organizing and self-configuring multi-hop wireless network, where the nodes are free to move randomly. Ad hoc wireless network are self-creating and self-organizing. MANET solves this problem they allow intermediate node to transmit data between two other nodes. To achieve this by MANETs are divided into two types into two types of networks, namely, single-hop and multi-hop. Thus, all nodes are free to move randomly.

Considering the fact that MANET [1][2] is becoming popular among critical mission applications, network security is of most importance. Because of open medium and remote distribution of nodes in MANET they are vulnerable to various types of attacks. Moreover due to distributed nature of market centralized monitoring system is not feasible. In such case, it is crucial to develop an intrusion- detection system (IDS) specially designed for MANETs.

To detect misbehaving nodes with the presence of false misbehavior report and to authenticate whether the destination node has received the reported missing packet through a different route and to achieve this we have to focus on the comparative study of ACK, SACK & MRA scheme so the proposed protocol advance EAACK is compared against popular mechanism such as TWOACK,AACK and EAACK in different scenario through simulation. Simulation parameters that are considered in this paper is packet delivery ratio and delay. The results is positive performances against TWOACK, AACK and EAACK in the cases of link breakage and source maliciousness. The drawbacks are delay and link breakage.

2.4. An Improvised Intrusion Detection System for MANETs

MANET is a collection of mobile nodes. It is more popular these days MANET has a decentralized network infrastructure. Thus all nodes are free to move randomly. A centralized infrastructure, which is often infeasible in mission vital applications like military conflict or emergency recovery. Intrusion detection is the act of detecting surplus traffic on a network or a device. To detect unwanted activity and events such as illegal, traffic that violates security policy, and traffic that violates acceptable use policies. Attack prevention measures, such as validation and encryption, can be used as the first line of defence for reducing the possibilities of attacks. However, these techniques have a restriction on the effects of prevention techniques in general and they are designed for a set of known attacks. They attacks that are designed for circumventing the existing security measures. In this paper we are implementing the method of digital signature with multiple key generation schemes to enhance security by dividing the key into slots and sending it to the receiver

Mobile Ad Hoc Network has always been prone to security attacks. Since the existing methods concentrate only on

detecting the malicious nodes we are not aware of the validity of the acknowledgement packets on which we fully rely on. So to ensure to validate the acknowledgement packets we digitally sign the keys and transmit the keys. We also implement a method of generating multiple key by dividing keys into slots. This leads to maximum network security for the present scenario without the loss of network performance.

3. Proposed system

In traditional networks many intrusion detection systems have been proposed, the routers, gateways or switches are used for network traffic. Hence, it is easy to implement IDS in these networks. In MANETs we do not use such devices. Moreover, due to its openness so both malicious and legitimate users can access. In mobile environment it is very difficult to separate normal and unusual activities. Sometimes the false routing information can be generated by outdated node or from a malicious node due to the arbitrarily movement of nodes. Thus, the available intrusion detection techniques used in simple wired networks cannot be implemented to MANETs directly. Researchers have developed many intrusion detection systems for the MANETs. In the next section, we briefly explain three existing techniques, i.e. Watchdog, TWOACK, and (AACK).

3.1. ACK

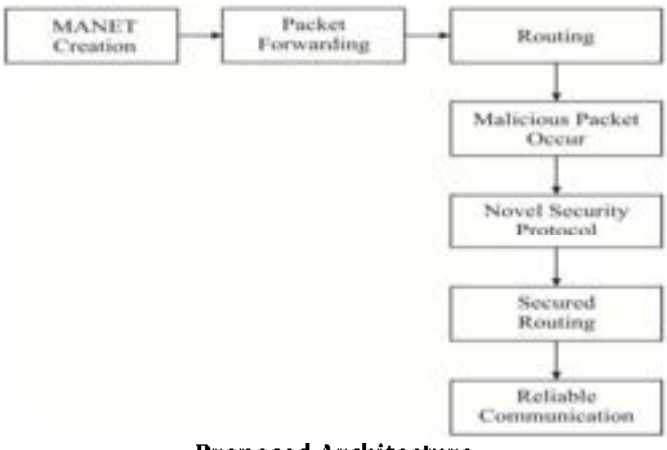
ACK is an end to end acknowledgment scheme. In EEACK it acts as a crossbreed scheme. The transmission from source to destination is successful when there is no misbehaving nodes. Then destination sends an acknowledgement packet to the source.

3.2. S-ACK

In the route the source sends S-ACK packet in the intention of detecting misbehaving nodes. After the packet reaches consecutive three nodes ahead the route the S-ACK sends the acknowledgement back to source. The third node is required to send the S-ACK acknowledgement to first node. S-ACK mode is the easy detection of misbehaving nodes in the limited power for transmission and the presence of receiver collision.

3.3. MRA

Misbehaviour Report Analysis (MRA) is a scheme. It is used to confirm misbehaviour report generated in S-ACK mode. This may be a false one as attacker may interfere in S-ACK scheme generating a false misbehaviour report.



Proposed Architecture

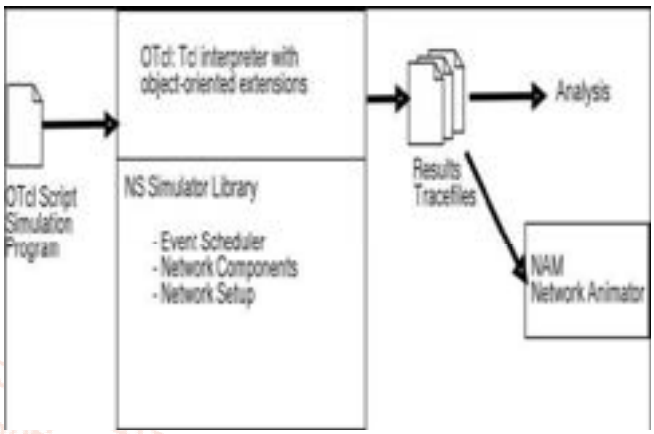
4. Explanation

4.1. The Network Simulator 2.33 (Ns2)

NS2 is developed at UC Berkeley it is a discrete event driven simulator. It is part of the VINT project. The objective of NS2 is to support networking research and education. NS2 is developed as a collaborative environment.

4.2. Structure of Ns2

Network simulator2 is built using object oriented methods in C++ and OTcl (object oriented variant of Tcl), NS2 interprets the simulation scripts written iOTcl.



Simplified User's View Of Ns

A subscriber has to set the different components up in the simulation environment. The user creates his simulation as a OTcl script. The event scheduler as the other component besides network components triggers the events of the simulation (e.g. sends packets, starts and stops tracing). Some parts of Network simulator2 are written in C++ for efficiency reasons.

4.3. Functionalities Of Ns2.33

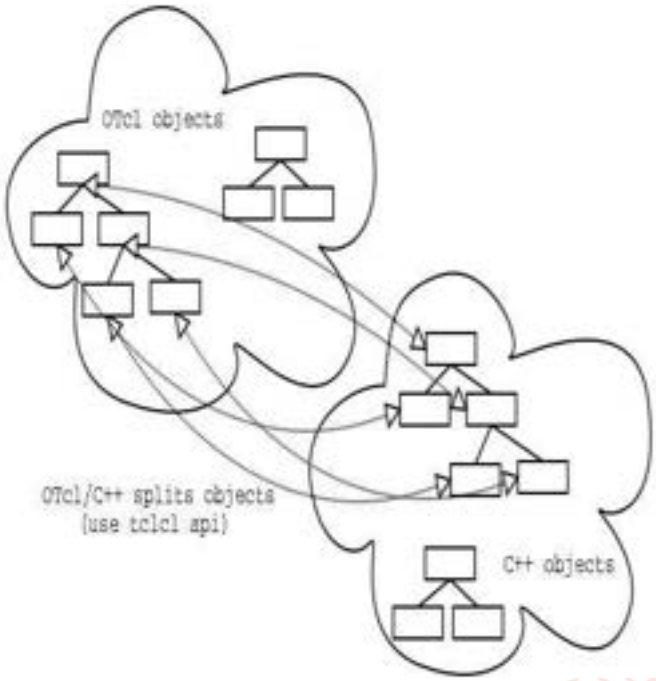
Functionalities for wired, wireless networks, tracing, and visualization are available in network simulator2.

- Support for the wired world include
- Routing DV, LS, and PIM-SM.
- Transport protocols: TCP and UDP for unicast.
- Traffic sources: web, ftp, telnet, cbr (constant bit rate), real audio.
- Different types of Queues: drop-tail, FQ, SFQ, DRR.
- Quality of Service: Integrated and Differentiated Services.
- Emulation.

- Support for the wireless world include
- Ad hoc routing with different protocols, e.g.
- AODV, DSR, DSDV, TORA
- Wired-cum-wireless networks
- Mobile IP
- Directed diffusion
- Satellite
- Senso-MAC
- Multiple propagation models (Free space, two-ray ground)
- Energy models

- Tracing
- Visualization
- Network Animator (NAM)
- Trace Graph

- Utilities
- Mobile Movement Generator



OTcl and C++: the duality

4.4. Mobile Networking In Ns2.33

This section describes the wireless model that was originally ported as CMU's(cracks me up) Monarch group's mobility extension to NS2. In this first section covers the original mobility model ported from CMU/Monarch group. Here we cover the internals of a mobile node, routing mechanisms and network components that are used to construct the network sk for a mobile node. The real CMU model allows simulation of pure wireless LANs or multihop ad-hoc networks.

4.5. The Basic Wireless Model In Ns

The wireless model fundamentally consists of the Mobile Node at the core, with additional supporting features that allows simulations of multi-hop ad-hoc networks.

The Mobile Node object is a split object. A major difference between them, though, is that the Mobile Node is not connected by means of Links to mobile nodes.

4.6. Mobile Node: Creating Wireless Topology

Mobile Node is the basic NS node object. It can be added with functionalities, ability to transmit and receive on a channel. It allows to be used wireless simulation environments, to create mobile.

Implementation Environment

NS2 can be used as the simulation tool. NS2 was chosen as the simulator partly because of the range of features it provides and partly because it has an open source code that can be modified and extended.

Network Simulator (Ns)

NS2 is an object–oriented, discrete event simulator for networking research. Even though the considerable confidence in NS, it is not a polished product yet and bugs are being finded and corrected continuously.

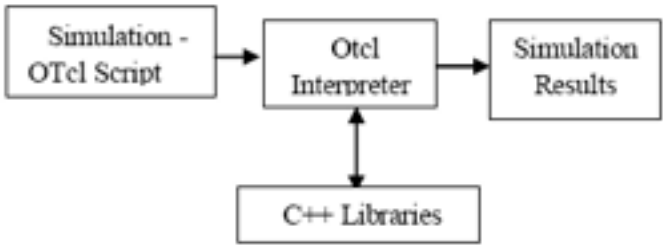
Network simulator2 is written in C++, with an OTcl1 interpreter as a command and configuration interface.

The C++ part, it is fast to run but slower to change, is used for detailed protocol implementation. One of the advantages of this split-language program approach is that it allows for fast generation of large events.

To simply use of simulator, it is sufficient to know OTcl NS can simulate the following:

1. **Topology:** Wired, wireless
2. **Scheduling Algorithms:** RED, Drop Tail,
3. **Transport Protocols:** TCP, UDP
4. **Routing:** Static and dynamic routing
5. **5.Application:** FTP, HTTP, Telnet, Traffic generators

4.7. User's View Of Ns-2



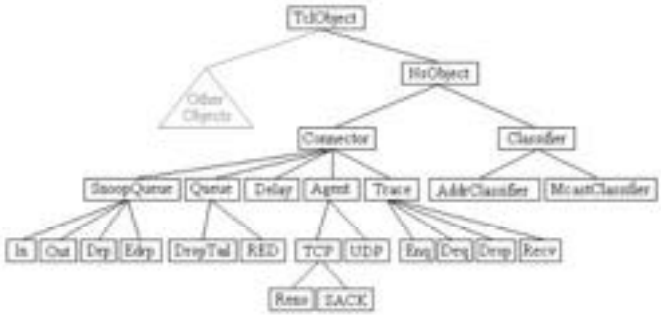
Block diagram of Architecture of NS-2

This section talks about the network simultor components, mostly compound network components. A partial OTcl class hierarchy of NS, which will used to help understanding the basic network components.

4.8. Class Tcl

The class Tcl (Telephone communication limited) encapsulates the actual instance of the OTcl interpreter and provides the methods to access and communicate with that interpreter, code. In this class provides methods for the following operations:

1. Obtain a reference to the Tel instance.
2. Invoke OTcl procedures through the interpret.
3. Store and lookup "Tcl Objects".



OTcl Class Hierarchy

4.8.1. Obtain a Reference to the class Tcl instance

A single instance of this class is declared in - tdcl/Tcl.cc as a static member variable.

4.8.2. Invoking OTcl Procedures

There are different methods to invoke an OTcl command through the instance, tcl.

1. **Passing Results to/from the Interpreter:** When the interpreter invokes a C++ scheme, it expects the result back in the private member variable, tcl-> result.

2. **Error Reporting and Exit:** In this method provides a uniform way to report errors in the compiled code.

4.9. Command Methods: Definition And Invocation

In every Tcl Object that is created, network simulator establishes the instance procedure, cmd{}, as a hook to executing methods through the compiled shadow object.

If there is no instance procedure called distance? the interpreter will invoke the instance procedure unknown{},it defined in the base class Tcl Object. The unknown procedure then invokes

$srmObject cmd distance? (agentAddre To show the operation through the compiled object's command()procedure. The user could explicitly invoke the operation directly.

For example,

```
        Agent/SRM/Adaptive instproc distance?
addr    {
        $self instvar distanceCache_($addr)
        if![info exists distanceCache_($addr)] {
        set distanceCache_($addr) [$self cmd distance? $addr]
        }
        set distanceCache_($addr)
        }
```

The following shows how the command() scheme using SRMAgent::command()

```
        Int ASRMAgent::command (int argc, const char*const*argv) {
        Tcl& tcl = Tcl::instance();
        if (argc == 3) {
        if (strcmp(argv[1], "distance?") == 0) {
        int sender = atoi(argv[2]);
        SRMinfo* sp = get_state(sender);
        tcl.tesultf("%f", sp->distance_);
        return TCL_OK; '
        }
        }
        return (SRMAgent::command(argc, argv));
```

The following observations are made from this code:
The function is called with two arguments. The argument (argc) indicates the number of arguments specified in the command line to the interpreter. The command line arguments vector (argv) consists of argv[0] contains the name of the method, "cmd" and argv[1] specifies the operation. In that this command method is defined for a class with multiple inheritance, one of two implementations can be chosen

1. Either they can invoke one of the parent's command method, and back to the result of that invocation.
2. They can each of the parent's command methods in some sequence, and back to the result of the first invocation that is successful. If none of them are successful, then they should back an error.

4.10. Mobile Networking In Ns

A major difference between them is that a mobile Node is not connected by means of Links to mobile nodes.

The common structure for defining a mobile node in ns2 is described as follows:

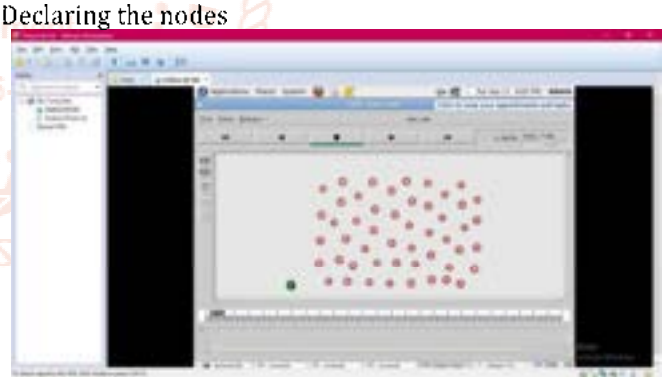
```
$ns node-config -adhocRouting $opt (adhocRouting)
        -IfType $opt (II)
        -macType $opt (mac)
        -ifqType $opt (ifq) -ifqLen $opt (ifqlen)
        -antType $opt (ant)
        -propInstance [new $opt (prop) -phyType $opt (netif)
        -channel [new $opt (chan)]]
        -topoInstance $topo
        -wiredRouting OFF
        -agentTrace ON
        -routerTrace OFF
        -macTrace OFF
```

The above API (application program interface) configures for a mobile node with all the given values of ad hoc-routing protocol, network stack, topography, propagation model, with wired routing turned on or off (required for wired-cum-wireless) and tracing turned on or off at different levels (router, mac, agent).

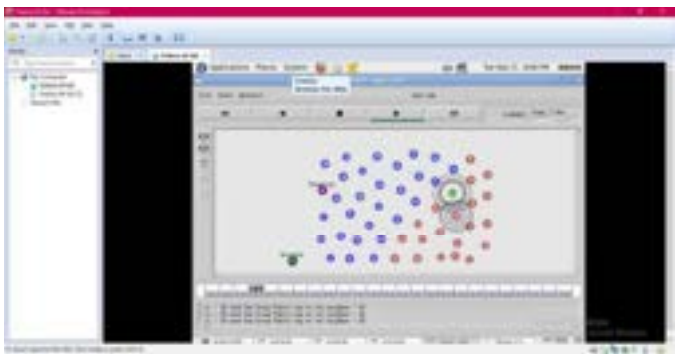
5. Result:

The simulation is conducted is with the Network Simulator (NS). The system is running on laptop with core 2 Duo t7250 CPU and 3GB RAM. The maximum hops allowed in this configuration setting are four. Both the physical layer and the 802.11 MAC layer are included in the wireless extension of NS2. The moving speed of mobile node is limited to 20m/s

Declaring the nodes



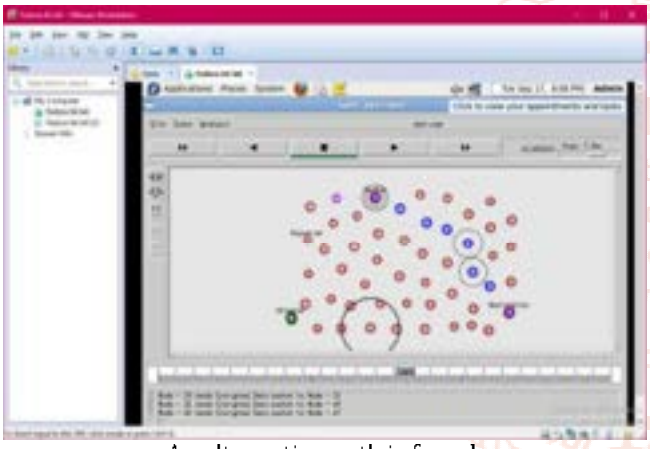
Broadcasting for finding the route for packet transmission.



A path is chosen from source to destination.

Declaring the source and destination nodes

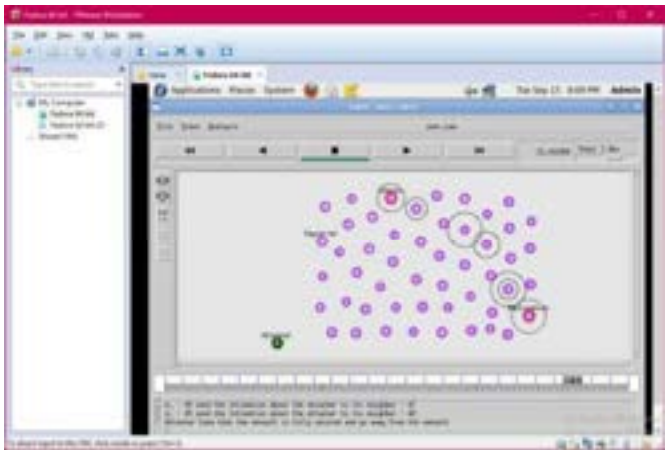
Searching the alternative path



An alternative path is found.

The attacker nodes are detected in the current path so searching for an alternative path without malicious.

The message was sent.



The implementation of the system to detect malicious attackers in MANETs is done and the message was sent without any attacks.

6. Conclusion:

To solve the security issue in MANETS we implemented new IDS based on enhanced adaptive Acknowledgment (EAACK). In this method every acknowledgment packet is digitally signed before sending in network and accepted only after verification. The limited transmission power and false misbehavior of nodes are completely removed in this scheme. Every acknowledgment packet received are authentic and untainted. This reduces the need for costly secure routing behaviors designed to mitigate the effects of an untrusted environment (and untrusted nodes) on the routing process. By preventing the entry of potentially untrustworthy nodes to the network, and thus the routing process, a MANET may be protected from subversion of its routing services at a lower cost, as malicious nodes are barred from the process entirely. This provides security to all data communicated over a MANET. It specifically targets the attributes of MANETs, it is not suitable for use in other types of network at this time. It sacrifices adaptability to a range of networks, to ensure that MANET communication is completely and efficiently protected. A single efficient method protects routing and application data, ensuring that the MANET provides reliable, confidential and trustworthy communication to all legitimate node.

In real time environment this project can be extended further for many applications . To improving the encryption technique further studies is needed. it is time consuming process for reconstructing the message, which can be reduced further. The optimized routing techniques can be incorporated the finding shortest path.

ABSTRACT

Gas leakage is a major problem with industrial sector, residential premises etc. One of the preventive methods to stop accident associated with the gas leakage is to install a gas leakage detection kit at vulnerable places. The aim of this project is to present such a design that can automatically gas booking, detect, alert and control gas leakage.LPG cylinders have become an integral part of every home. Our kitchens are occupied with LPG cylinders which help us make delicious food. But it can be dangerous and life threatening. The aim of this project is to design a safety-oriented system which will alert the user about any threat in the kitchen through mobile and given the buzzer sound. This system will detect leakage of LPG and send an alert message to the user, at the same time it will switch off the gas supply of LPG by switching regulator-switch using BO motor. It is also used to monitoring the high voltage passing through the home appliances and it will reduce the voltage level in the power supply. It ensures safety from any gas leakage accident like explosion. As an additional advantage, this system has a weighing sensor which can measure the weight of the cylinder and regularly update user about gas left in the cylinder and automatically booking the cylinder. This project proposes a system that will make entire LPG cylinder booking procedure automated without human intervention. This system continuously measures the weight of the cylinder and once it reaches minimum threshold it will automatically sends SMS to the authorized LPG Agent so that they can deliver the LPG cylinder in time. Along with the Automated cylinder booking we also designed feature related to the safety of the user in which it continuously monitor the leakage of LPG gas and alerts the user regarding leakage to avoid major accidents which costs human lives mostly.

CHAPTER 1
INTRODUCTION

1.1 **Introduction**

Liquefied petroleum gas is being used for the past decades as industrial fuel and for domestic purpose. It has a characteristic of smokeless burning in the air. The main constituents of LPG are propane and butane and depending on the applications their proportions vary. Gas leakage detection in residential houses has become one of the fundamental issues in the recent times. Accidents mainly occur due to the negligence and technical fault. Electronic and press media have reported many accidents which were caused mainly because of gas leakage in residential houses and industries. A better system needs to be developed to reduce the accidents because of gas leakage. The gas is generally stored in metallic cylinders as its boiling point is lower than ambient temperature. Gas is molecularly heavy than other gases present in the air.

So whenever the gas is leaked it settles closest to the ground level. And unless you provide a powerful exhaust system it cannot be forcefully disposed into open atmosphere. Now-a-days LPG leakage detection in homes, restaurants has been a common issue and the detection systems find applications in the market. Presently they are using load cell to measure the weight of the cylinder. When they find it become empty, consumer will order for a new cylinder. There may be a delay in providing the cylinder for few reasons like we may inform the service provider at the last moment when the gas is empty or there may be a delay in informing the gas provider. So in this system we will use a load cell to measure the amount of gas present in the cylinder and also book the gas automatically when it reaches to a certain level.

This system helps you to upgrade your safety standards, complete statutory requirements on environmental commitments and most important and basic function being prevented accidents and protect life and property from disaster. In the past, it has been a conventional practice to employ combustion apparatus such as a furnace, heater, stove or LPG kit in cars, which utilizes a combustible vapor or gas to produce heat energy when properly ignited. In the use of combustible apparatus in which a combustible gas such as

natural or liquid propane gas is burned in heating boilers, domestic water heaters, ovens, stoves and the like, the apparatus or appliance is generally of an automatic recycling type.

That is to say, the equipment is generally in operation for short periods of time after which is shut down for a short period of time. The equipment has intermediate operation and the appliance is generally started and stopped at the signal of an automatic controller, such as a thermostat, which may be actuated by temperature, pressure, or the like. The LPG Kit installed is many times installed inside the car creating possibilities of large accidents.

This type of appliance/Kits is normally unattended by any operating personnel, since it is automatic in operation and, therefore, one hazard encountered in the use of such an appliance is the possibility that during a standby period or a period in which it is not in operation, a gas leak may occur thereby resulting in a large accumulation of combustible gas which can produce an explosion if the detection is not quickly notice.

CHAPTER 2
LITERATURE SURVEY

2.1 Arduino Based LPG gas Monitoring and automatic Cylinder booking with Alert system

R.NareshNaik, P.SivaNagendra Reddy, S.Nanda Kishore, K.Tharun Kumar Reddy " LPG gas Monitoring and automatic Cylinder booking with Alert system" IOSR Journal of Electronics and Communication Engineering, .Volume 11, Issue 4, Ver. I (Jul.-Aug .2016),

2.1.1 Introduction

There are approximately 30crore LPG users in the country in which mostly 40% of the population. The Several standards have been implemented for the gas leakage detection system. The existing systems provides an alarm system which is mainly meant to detect an Gas leakage in the house and commercial premises. The objective of the proposed system is to continuously measure the weight of the cylinder and as soon as it reaches the minimum threshold it will automatically sends an SMS alert to the user as well as Authorized LPG agent so that they can act accordingly. This system also designed to detect LPG gases such as propane and butane. The allowed level for butane is 600ppm above which it is considered to be of high level and poses a danger. The threshold level of weight of the cylinder is used for automatic cylinder booking.

2.1.2 Techniques

- Arduino board is powerful development platform based on ATMEGA328 microcontroller.
- Bluetooth HC-05 module is used.
- LM35 temperature sensor is used to sense the temperature.

2.1.3 Result

In Arduino Based LPG gas Monitoring & Automatic Cylinder booking with Alert System MQ-4 gas sensor, LM-35 Temperature sensor, and 10 kg load cell (for prototype) as input devices and piezoelectric buzzer, 16x2 LCD display and GSM module used as output devices.

2.1.4 Drawback

- Gas sensor shouldn't be enough sensitive to detect gas leakage.

2.2 Smart LPG monitoring & automatic gas booking system

Shashikumar, PranitaPadole, Shweta salve, Adityasachdev, Prof. M.P. Wankhade5 "smart LPG monitoring & automatic gas booking system" International Research Journal of Engineering and Technology, Volume: 05 Issue: 04 | Apr-2018

2.2.1 Introduction

Today in this present area where technological advances are at its vertex, there is not even a single sector which remains untouched by technology. Technology has not merely established our lives simpler, but also offers a high level of safety and security wherever required. Technological devices are available which provides refuge for all the mankind. In our day to day lives, we all use cooking fuel for cooking our daily meals, but if this fuel gets leaked due to some or the other way and then there is a large possibility of a calamity to occur around. Hazards due to gas leakage are dangerous can cause loss of consciousness or even death. Overall health of a person is badly affected causing dizziness, fatigue, nausea, headache, irregular breathing.

Several standards have been implemented for the gas leakage detection system. There are many existing systems which can detect leakage using different gas sensors. Developed systems have used arduino mega, MQ-2 gas sensor, and some other components. For automatic cylinder booking there is an existing system that does booking using GSM.

2.2.2 Techniques

- Arduino board is powerful development platform based on ATMEGA328 microcontroller.
- Bluetooth HC-05 module is used.
- LM35 temperature sensor is used to sense the temperature.

2.2.3 Result

This monitoring system can be further enhanced by using Ethernet in place Bluetooth module in order to operate from anywhere, which supports the another real-time application. For industrial purposes , robot can be developed for detecting multiple gas concentrations and fire.

2.2.4 Drawback

- Gas sensor shouldn't be enough sensitive to detect gas leakage.

2.3 Gas Leakage Detection and Automatic Gas Booking Alert System using IOT

Anusuya, Kanimozhi, Ruthann, "Gas Leakage Detection and Automatic Gas Booking Alert System using IOT"International Journal of Engineering Research & Technology (IJERT), ISSN: 2278-0181(2019).

2.3.1 Introduction

The main objective of this research is automatic protection from the LPG (Liquefied Petroleum Gas) leakage or reduction of the hazards that can be caused due to unawareness of the user about the gas leakage and also providing an automatic gas booking facility by applying advance communication technology. If there is any gas leakage from storage tank, service station or from the automobile then a buzzer will turn ON and an alert message will be sent to a pre-set mobile number by using GSM (Global System for Mobile communication) technology.

Sound from the alarm as well as message in the mobile number will give valuable suggestion to the users so that they can prevent themselves from dangerous effect of LPG gas leakage. Proposed model notifies alert to people before any leakage from the

gas cylinder and also automatically books for refilling of gas from the gas booking center before the cylinder gets empty. Here we have developed an Arduino based LPG gas detector alarm. If gas leakage occurs, this system detects it and makes an alert by buzzing the buzzer attached with the circuit.

2.3.2 Techniques

- GSM is used to convey the information to the user.Weight sensor is used to measure the gas level of the cylinder.MQ-2 sensor response time is very fast.

2.3.3 Result

This model, gas spillage recognition has been given a most elevated need. MQ2 set in the region of the gas chamber. In the appearance of spillage, the obstruction of the sensor diminishes expanding its conductivity. Relating beat is sustained to microcontroller and at the same time switches on the ringer and fumes fan which we can reset by a manual reset switch.

2.3.4 Drawback

- MQ-2 sensor is very low sensitive and cost is high.
- It doesn't have capability monitor the any short to present in the home appliances.

2.4 LPG leakage detection and smart gas booking

PurvaDuggal, AkshayPawar, PoorvaKalkatte, Prof. RushikeshBhalerao, "LPG leakage detection and smart gas booking"International Research Journal of Engineering and Technology, Volume: 05 Issue: 11 | Nov 2018

2.4.1 Introduction

The smart phones aren't only used for business purpose however they need innumerable uses. Gas Detectors are within the marketplace for a really very long time and are immensely used.In leakage detection module the leakage in pipe is detected using the

MQ-2 sensor which is interfaced with the android application .User gets the notification when leakage is detected in pipe and respected actions can be taken.

There are several existing systems which can discover leakage using completely different gas sensors. Developed systems have used arduino mega, MQ-2 gas device, and some alternative parts. Systems developed until date has either a gas detection module or automatic cylinder booking module. We've got developed a paradigm that has both the options that are of leakage detection and gas booking.

The system detects the escape of the LPG using MQ-2 gas sensor and alerts the consumer regarding the gas escape by sending SMS. Once the system identifies that LPG concentration within the air reaches the specified level then it alert the consumer by sending SMS to registered mobile phone and blinks the light. It should additionally enable the service supplier to look at all such requests and to notify the users once their requests are met.

2.4.2 Techniques

- GSM is used to convey the information to the user.Weight sensor is used to measure the gas level of the cylinder.MQ-2 sensor response time is very fast.

2.4.3 Result

The proposed gas leakage detector is promising within the field of safety. The attempt whereas creating this paradigm has been to bring a revolution within the field of safety against the leak of harmful and toxic gases to minimize and thus nullify any major or minor hazard being caused due to them. Our system is reasoned to assist customers to upgrade their safety norms, act in consequently with minimum needs on environmental problems and largely the basic function being prevented by major disasters and protect life and property from reputed Accidents.

2.4.4 Drawbacks

- MQ-2 sensor is very sensitive.

- Cost is very high.

2.5 Gas Leakage Detection System byUsing ZigBee Technology

Jading, Juwan, Yuan, and Pan, "The Monitoring System of Leakage Accidents in Crude Oil Pipeline based on ZigBee Technology", IEEE Changzhou University, 2011.

2.5.1 Introduction

In recent years, the leakage accidents in the pipeline transportation occur frequently. So how to make the effective detection and accurate localization for pipeline leakage is an important work, which could help maintaining safe running of pipeline transportation. Traditionally, the pipeline leakage monitoring system is realized by communication cable system. The cost of installation and maintenance are very expensive and difficult.

In order to overcome these restrictions, wireless sensor network for monitoring is definitely the best choice in the situation above. ZigBee is a good wireless networking technology with features of low power consumption, low cost and self-organized. For these features the technology is wildly used in the pipeline leakage monitoring application field. The goal in this paper is to propose and develop a pipeline leakage monitoring system for running of pipeline transportation based on ZigBee technology.

2.5.2 Techniques

- ATmega128L is a low power CMOS.MQ-2 gas sensor has high sensitivity to Natural gas, Methane and could be used to detect both Methane and Propane.
- The sensor could be used to detect different combustible gas especially Methane, its low cost and suitable for different application.

2.5.3 Result

The sensor nodes could get into sleep if there is no task or event and wake up as external triggers occur. The routing node chooses a channel after scanning the RF environment for existing networks and then starts the PAN. When the sensor nodes are permitted to join the PAN, the pressure sensors start to collect data and transmit the data package to the routing nodes.

2.5.4 Drawback

- The drawback that there is no control action taken, which need manual control which increase risk to human handling.
- The second method has the disadvantage that if the wiring of the exhaust fan is not proper then it will directly cause the explosion due to the flow of AC.

2.6 Gas Leakage Detection and Auto ON-OFF System.

R.NareshNaik, P.SivaNagendra Reddy, S.Nanda Kishore, K.Tharun Kumar Reddy " LPG gas Monitoring and automatic Cylinder booking with Alert system" IOSR Journal of Electronics and Communication Engineering, .Volume 11, Issue 4, Ver. I (Jul.-Aug .2016),

2.6.1 Introduction

This system helps you to upgrade your safety standards, completely statutory requirements on environmental commitments and most important and basic function being prevent accidents and protect life and property from disaster. In the past, it has been a conventional practice to employ combustion apparatus such as a furnace, heater, stove or LPG kit in cars, which utilizes a combustible vapor or gas to produce heat energy when properly ignited. In the use of combustible apparatus in which a combustible gas such as natural or liquid propane gas.

That is to say, the equipment is generally in operation for short periods of time after which is shut down for a short period of time. The equipment has intermediate

operation and the appliance is generally started and stopped at the signal of an automatic controller, such as a thermostat, which may be actuated by temperature, pressure, or the like. The LPG Kit installed is many times installed inside the car creating possibilities of large accidents. This type of appliance/Kits is normally unattended by any operating personnel, since it is automatic in operation and, therefore, one hazard encountered in the use of such an appliance is the possibility that during a standby period or a period in which it is not in operation, a gas leak may occur thereby resulting in a large accumulation of combustible gas which can produce an explosion if the detection is not quickly notice.

Ideal sensor for use to detect the presence of a dangerous LPG leak in your car or in a service station, storage tank environment. This unit can be easily incorporated into an alarm unit, to sound an alarm or give a visual indication of the LPG concentration. The sensor has excellent sensitivity combined with a quick response time. The sensor can also sense is butane, propane, LNG and cigarette smoke

2.6.2 Techniques

- GSM is used to convey the information to the user.
- MQ2 sensor response time is very fast and it convey the information very fastly.

2.6.3 Result

The leakage is detected by gas sensor and the information is convey to the user. The message "gas is low recharge soon" is sent to the user when the LPG gas reaches to minimum threshold level. So the user comes to know to when to book the cylinder to avoid delay in delivering cylinder. The message "gas is empty recharge immediately" is sent when the weight of the gas is fully empty.

2.6.4 Drawback

- It work only when at 5V power supply is given.
- Its sensitivity depends on Humidity and temperature.

2.7 Automatic gas booking and leakage detection using embedded system with safety guards

G.Rathanasabhapathy1, B.Durga Devi2, N.Gopi Krishnan3, S.Gowsalya4, M.Jagadeesan5,1Assistant Professor, 2,3,4,5UG students

2.7.1 Introduction

The main objective of our project is to continuously measures the weight of the cylinder by load cell and when the weight of the cylinder goes below the set value it sends message to the gas agency for the booking and another message to the owner. It also reduces the human efforts also became easy for illiterate person. When the temperature of the room goes above 50C it turns ON the buzzer and sends message "Your kitchen temperature is very high than normal" to the owner. The main purpose of our project is to avoid accidents due to leakage of LPG as safety is an important part. This system is also detects LPG gases such as butane and propane. The range of MQ6 sensor is from 200-10000 ppm. When the level of butane goes above 600 ppm which is considered as dangerous for human the system sends a message "LPG leakage is detected in your kitchen" to the owner.

Home automation or smart homes (also known as domestic) can be described as introduction of Technology within the home environment to provide convenience, comfort, security and energy efficiency to its occupants. With the introduction of IOT, the research and implementation of home automation are getting more popular. Various wireless technologies that can support some form of remote data transfer, sensing and control such as Bluetooth, WI-FI, RF Id and cellular network have been utilised to embed various levels of intelligence in the home.

2.7.2 Techniques

- MQ-4 gas sensor is used in gas leakage detection equipment.LM35-integrated circuit sensor that can be used to measure the temperature. GSM is used to convey the information to the user.

2.7.3 Result

In this paper we have used automatic gas booking with alert system without human intervention. Our system helps customers to upgrade their safety and protect life and property from reputed accidents. The main objective of our system is to measure the gas present in cylinder when the weight of cylinder is below the fixed load by using weight sensor. The gas agency gets the order of new cylinder and owner received the messages regarding the status .

2.7.4 Drawback

- Gas sensor shouldn't be enough sensitive to detect gas leakage.

2.8 LPG Gas Auto Booking By GSM and Leakage Detection with Auto Switchable Exhaust Fan

Anusuya, Kanimozhi, Ruthann, **"**Gas Leakage Detection and Automatic Gas Booking Alert System using IOT"(International Journal of Engineering Research & Technology (IJERT)), ISSN: 2278-0181(2019).

2.8.1 Introduction

LPG gases have been widely used in home appliances, industry and motor fuel, More than 50% of the heaters use LPG as cooking is well done using LPG , Most important task is detection and identifying LPV (linear parameter varying) model used in the gas industry , Leakage detection is used in household safety ,The main causes of accidents in gas pipeline are corrosion, external interference, construction defects, ground movement and material failure. Transport, through the pipes is the safest but it does not mean that pipes are risk-free .

Leakage detection is classified according to technical nature , Non-technical leakage detection like are hearing, smelling and seeing or looking. Sometimes trained dogs are also used , Technical nature means both hardware and software. Hardware methods mean acoustic, cable sensor, optical, soil monitoring. Software based means continuously

monitoring the state of pressure, flow rate or other pipeline parameters , Low levels of LPG leak can avoid any possible accidents.

2.8.2 Techniques

- Arduino board is powerful development platform based on ATMEGA328 microcontroller.
- Bluetooth HC-05 module is used.
- LM35 temperature sensor is used to sense the temperature.

2.8.3 Result

By testing the system prototype model it is found that when a small amount of LPG is introduced near the gas sensor the system detects the leakage and sends an alert message to the consumer by using the GSM module. Simultaneously the audio-visual indicator is activated and the exhaust fan is switched ON. The system prototype also monitors the gas level of the cylinder, books the new cylinder automatically and also sends an alert message to the consumer to remind about the refilling of the cylinder before the cylinder becomes empty.

2.8.4 Drawback

- MQ-2 sensor is very low sensitive and cost is high.
- It doesn't have capability monitor the any short to present in the home appliances.

2.9 GSM Based Gas Leakage Warning System

Taveras Ismail1, Devoleena Das2, Jyotirmoy Saikia3, Jyotirmoy Deka4, Raj Kumar Sarma5 Assistant Professor, Department of ECE,, Guwahati, India1, Guwahati, India2, 3, 4, 5 Assam Don Bosco University.

2.9.1 Introduction

This type of appliance/Kits is normally unattended by any operating personnel, since it is automatic in operation and, therefore, one hazard encountered in the

use of such an appliance is the possibility that during a standby period or a period in which it is not in operation, a gas leak may occur thereby resulting in a large accumulation of combustible gas which can produce an explosion if the detection is not quickly noticed. Although some sophisticated detector means have been provided, it is contemplated that the indicator means should be simple and economical so that the entire system may be readily incorporated into mobile trailers, campers, boats and other vehicles or living quarters having appliances dependent upon storage of pressurized gas.

Gas leakage detection is not only important but stopping leakage is equally essential. This paper provides a cost effective and highly accurate system, which not only detect gas leakage but also alert (Beep) and turn off main power and gas supplies, and send an SMS. GSM module is used which alert the user by sending an SMS. In order to provide high accuracy gas sensor MQ-6 has been used.

2.9.2. Techniques

- GSM is used to convey the information to the user.Weight sensor is used to measure the gas level of the cylinder.
- MQ-2 sensor response time is very fast.

2.9.3 Result

Gas leakages in households and industries cause risk to life and property. A huge loss has to be incurred for the accident occurred by such leakages. A solution to such a problem is to set up a monitoring system which keeps on monitoring the leakage of any kind of flammable gases and protects the consumer from such accidents. In addition to this, it activates an alarm as well as sends a message to the user.

2.9.4 Drawback

- MQ-2 sensor is very low sensitive and cost is high.
- It doesn't have capability monitor the any short to present in the home appliances.

2.10 Gas Level Monitoring and Auto Booking Using IOT with Leakage Alert

L.Ramanathan, M.AnilKumar,M.KranthiKumar,R.LohithMithra Reddy
SCOPE,VIT University, Tamil Nadu, 632014,India

2.10.1 Introduction

LPG is comprised of Commercial-Propane and Commercial-Butane having immersed too some sun soaked hydrocarbons. On account of its flexible nature of LPG, It is utilized as a part of numerous necessities, for example, household fuel, mechanical fuel, auto-versatile fuel, light and so on and the interest for LPG is consistently expanding step by step. The condensed oil gas is utilized generally in houses,

LPG makes less smoke and does not create much problem to the earth. Gaseous petrol is another generally utilized fuel in houses. The two consumes to create clean vitality, however there is a bona fide chance about the spillage. The gases being 5 times heavier than air don't scramble easily and may provoke suffocation when breathed in additionally the spillage gases when touched off may prompt blast. The quantity of passing's because of the blast of gas barrels has been expanding as of late.

Different techniques for gas booking are available in current framework. The framework demonstrates that some is additional time required to convey LPG in the wake of booking. There is no such office of consistent gas level observing framework. And furthermore there is no arrangement for gas spillage discovery and control activity on gas spillage. We as a whole are extremely occupied in our day by day life and it is hard to know the status of LPG gas chamber. On the off chance that LPG will complete without advising us it can make exceptionally troublesome condition for cooking and so forth. There is no office for gas spillage discovery and control activity.

2.10.3 Techniques

- GSM is used to convey the information to the user.
- MQ2 sensor response time is very fast and it convey the information very fastly.

2.10.3 Result

In micro-controller Based gas Monitoring and Automatic Cylinder booking with notification System MQ-2 gas sensor, LM-35 Temperature sensor, 10 kg stack cell (for model) as info gadgets and Piezoelectric bell, 16x2 LCD show and IOT Terminal utilized as yield gadgets.

2.10.4 Drawback

- The per-unit charge on roaming calls is higher in GSM.
- Initial cost is very high

2.11. Summary of Literature Survey

Table 2.1.Summary of Literature Survey

S.NO	TITLE	TECHNIQUES	DRAWBACK
1.	Arduino Based LPG gas Monitoring and automatic Cylinder booking with Alert system.	MQ-4 gas sensor is used in gas leakage detection eqsuipment.LM35-integrated circuit sensor that can be used to measure the temperature.	MQ-4 gas sensor is very high sensitive and cost is very high.
2.	Smart LPG Monitoring and Automatic Gas Booking System.	Arduino board is powerful development platform based on ATMEGA328 microcontroller.	Gas sensor shouldn't be enough sensitive to detect gas leakage.

3.	Gas Leakage Detection and Automatic Gas Booking Alert System using IOT.	GSM is used to convey the information to the user.Weight sensor is used to measure the gas level of the cylinder.MQ-2 sensor response time is very fast.	MQ-2 sensor is very high sensitive and cost is high. It doesn`t have capability moniter the any short to present in the home appliances.
4.	LPG leakage detection and smart gas booking	GSM is used to convey the information to the user.MQ2 sensor response time is very fast and it convey the information very fastly.	MQ-2 sensor is very sensitive. Cost is very high.
5.	LPG Gas leakagedetection and Alert system.	GSM is used to convey the information to the user.Weight sensor is used to measure the gas level of the cylinder.MQ-2 sensor response time is very fast.	It only gives alarm sound and does not give any information to the user. The gas sensor is very sensitivity.
6.	Gas leakage detection and Auto ON-OFF	Ideal sensor is use to detect the gas leakage.	It only used for detection purpose it cannot give any information about

	Gas system.		the cylinder weight.
7.	Automatic gas booking and leakage detection using embedded system with safety guards	Weight sensor is measured for cylinder weight	It only used for detection purpose it cannot give any information about the cylinder weight.
8.	LPG Gas Auto Booking By GSM and Leakage Detection with Auto Switchable Exhaust Fan	MQ-2 gas sensor is used to detect the gas leakage. It is made of sno2.	It detect only gas leakage and doesn't booking the cyclinder automatically.
9.	GSM Based Gas Leakage Warning System.	MQ-6 sensor is used detect the gas leakage. It is made up of sno2. GSM is used to convey the information to the user . LCD and RF link used to display the fault of the Stepper motor IC used to turn off the gas supplies	Gas sensor shouldn't be enough sensitive to detect gas leakage.
10.	LPG gas auto booking by GSM and leakage detection with auto	MQ-2 gas sensor is used to detect the gas leakage. It is	It only gives alarm sound and does not give any

	switchable exhaust fan.	made of sno2. PIC16F628A 8 bit microcontroller is as the brain of the whole system to control all the processes.It has an inbuilt ADC.	information to the user. The gas sensor is very sensitivity. It does not ON and OFF the gas cylinder while the gas leaking.

CHAPTER 3
THEORETICAL BACKGROUND

3.1 Existing System

This existing project is to sense the LPG Gas leakage in the house and automatically trip an EB main power in RF technology with the help of microcontroller. In this project used for wireless energy transmitter with house security system, using Energy meter and also monitoring it through PC via wireless technology**.** This project is very useful to the EB board because there is no need of employee to take consumed power unit in the every house.

Existing block diagram

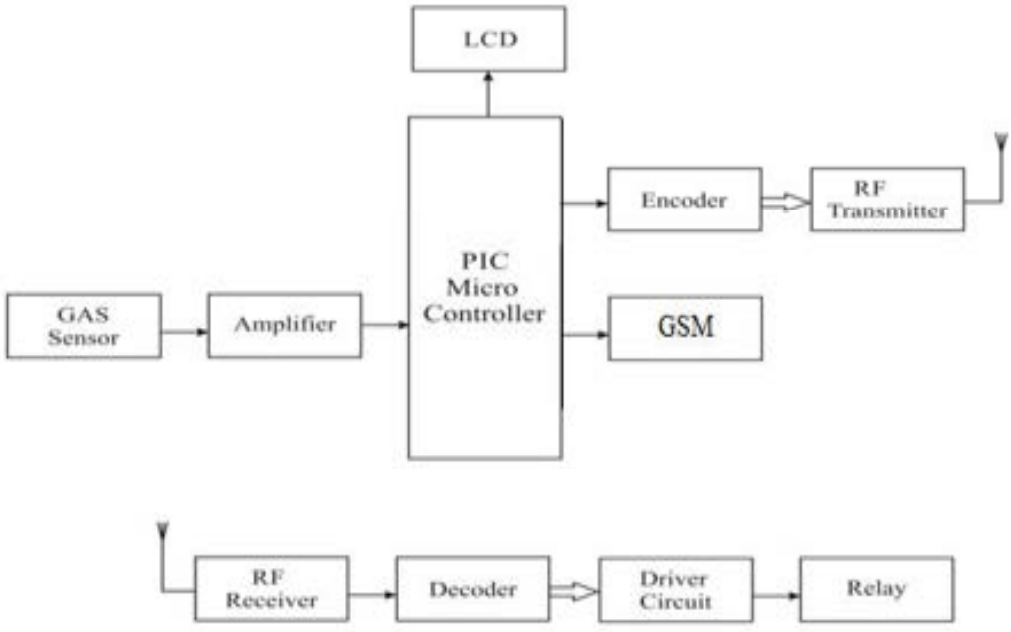

Figure 3.1 Existing System Block Diagram

3.2 Proposed Method

This proposed system used electronic instrument, which is used to measure the LPG gas cylinder weight. Its goes to lower weight means it will send a SMS

automatically. If LPG gas leakage detection find at home it automatically shut down the EB and make the alarm.

Proposed block diagram

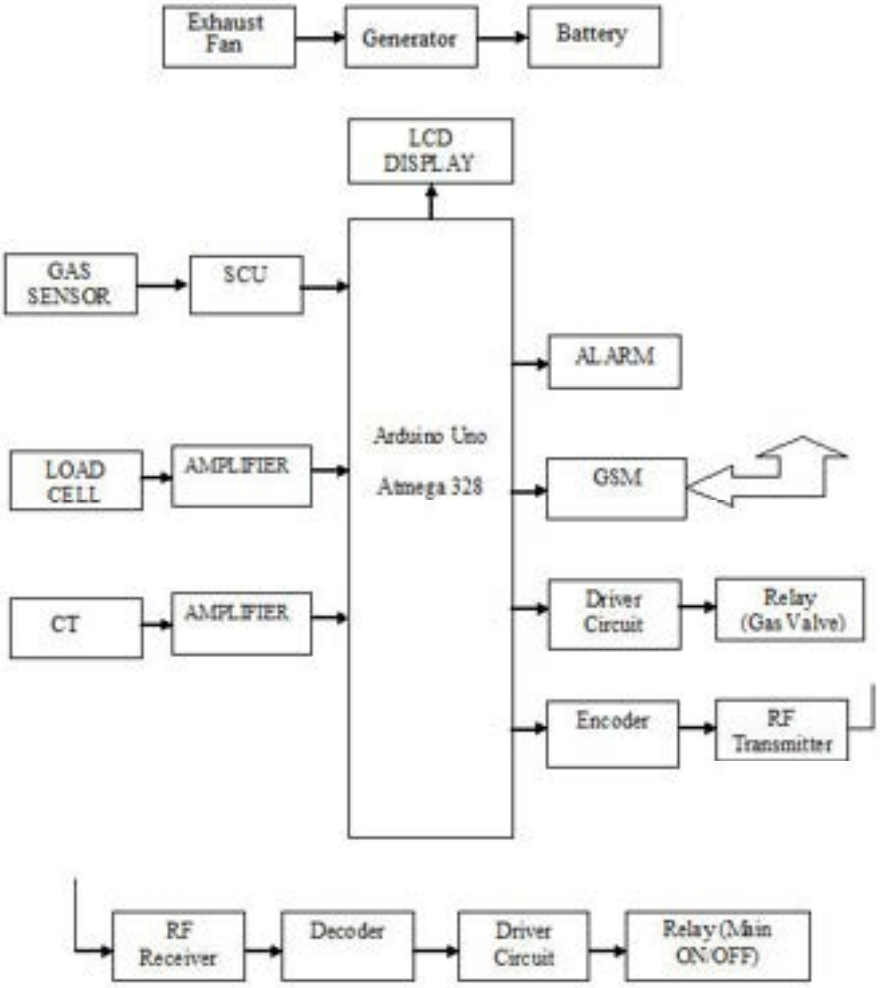

Figure 3.2 Proposed System Block Diagram

Gas leakage is a major problem with industrial sector, residential premises etc. One of the preventive methods to stop accident associated with the gas leakage is to install a gas leakage detection kit at vulnerable places. The aim of this project is to present such a design that can automatically gas booking, detect, alert and control gas leakage. LPG cylinders have become an integral part of every home. Our kitchens are occupied with LPG cylinders which help us make delicious food. But it can be dangerous and life

threatening. The aim of this project is to design a safety-oriented system which will alert the user about any threat in the kitchen through mobile and given the buzzer sound. This system will detect leakage of LPG and send an alert message to the user, at the same time it will switch off the gas supply of LPG by switching regulator-switch using BO motor. It is also used to monitoring the high voltage passing through the home appliances and it will reduce the voltage level in the power supply. It ensures safety from any gas leakage accident like explosion.

As an additional advantage, this system has a weighing sensor which can measure the weight of the cylinder and regularly update user about gas left in the cylinder and automatically booking the cylinder. This project proposes a system that will make entire LPG cylinder booking procedure automated without human intervention. This system continuously measures the weight of the cylinder and once it reaches minimum threshold it will automatically sends SMS to the authorized LPG Agent so that they can deliver the LPG cylinder in time. Along with the Automated cylinder booking we also designed feature related to the safety of the user in which it continuously monitor the leakage of LPG gas and alerts the user regarding leakage to avoid major accidents which costs human lives mostly.

CHAPTER 4
SYSTEM SPECIFICATIONS

4.1 SOFTWARE REQUIREMENTS

- Arduino IDE
- PCB Designing
- Embedded C

4.1.1 ARDUINO SOFTWARE (IDE)

- Writing Sketches
- File
- Edit
- Sketch
- Tools
- Help
- Sketchbook
- Tabs, Multiple Files, and Compilation
- Uploading
- Libraries
- Third-Party Hardware
- Serial Monitor
- Preferences
- Language Support
- Boards

The Arduino Integrated Development Environment - or Arduino Software (IDE) - contains a text editor for writing code, a message area, a text console, a toolbar with buttons for common functions and a series of menus. It connects to the Arduino and Genuine hardware to upload programs and communicate with them.

4.1.2 PCB Designing

Design and Fabrication of Printed circuit boards

4.1.2.1 Introduction

Printed circuit boards, or PCBs, form the core of electronic equipment domestic and industrial. Some of the areas where PCBs are intensively used are computers, process control, telecommunications and instrumentation.

4.1.2.2 Manufacturing

The manufacturing process consists of two methods; print and etch, and print, plate and etch. The single sided PCBs are usually made using the print and etch method. The double sided plate through – whole (PTH) boards are made by the print plate and etch method.

The production of multi-layer boards uses both the methods. The inner layers are printed and etch while the outer layers are produced by print, plate and etch after pressing the inner layers.

4.1.2.3 Software

The software used in our project to obtain the schematic layout is MICROSIM.

4.1.2.4 Panelisation

Here the schematic transformed in to the working positive/negative films. The circuit is repeated conveniently to accommodate economically as many circuits as possible in a panel, which can be operated in every sequence of subsequent steps in the PCB process. This is called penalization. For the PTH boards, the next operation is drilling.

4.1.2.5 Drilling

PCB drilling is a state of the art operation. Very small holes are drilled with high speed CNC drilling machines, giving a wall finish with less or no smear or epoxy, required for void free through whole plating.

4.1.2.6 Plating

The heart of the PCB manufacturing process. The holes drilled in the board are treated both mechanically and chemically before depositing the copper by the electro less copper platting process.

4.1.2.7 Etching

Once a multiplayer board is drilled and electro less copper deposited, the image available in the form of a film is transferred on to the outside by photo printing using a dry film printing process. The boards are then electrolytic plated on to the circuit pattern with copper and tin. The tin-plated deposit serves an etch resist when copper in the unwanted area is removed by the conveyor's spray etching machines with chemical etch ants. The etching machines are attached to an automatic dosing equipment, which analyses and controls etch ants concentrations

4.1.2.8 Soldermask

Since a PCB design may call for very close spacing between conductors, a solder mask has to be applied on the both sides of the circuitry to avoid the bridging of conductors. The solder mask ink is applied by screening. The ink is dried, exposed to UV, developed in a mild alkaline solution and finally cured by both UV and thermal energy.

4.1.2.9 Hot Air Leveling

After applying the solder mask, the circuit pads are soldered using the hot air leveling process. The bare bodies fluxed and dipped in to a molten solder bath. While removing the board from the solder bath, hot air is blown on both sides of the board through air knives in the machines, leaving the board soldered and leveled. This is one of the common finishes given to the boards. Thus the double sided plated through whole printed circuit board is manufactured and is now ready for the components to be soldered.

4.1.3 Embedded C

Embedded C is a set of language extensions for the C Programming language by the C Standards committee to address commonality issues that exist between C extensions for different embedded systems. Historically, embedded C programming

requires nonstandard extensions to the C language in order to support exotic features such as fixed-point arithmetic, multiple distinct memory banks, and basic I/Ooperations. In 2008, the C Standards Committee extended the C language to address these issues by providing a common standard for all implementations to adhere to. It includes a number of features not available in normal C, such as, fixed-point arithmetic, named address spaces, and basic I/O hardware addressing. Embedded C use most of the syntax and semantics of standard C, e.g., main () function, variable definition, datatype declaration, conditional statements (if, switch. case), loops (while, for), functions, arrays and strings, structures and union, bit operations, macros, unions,etc.

4.2 Hardware Requirements

- Arduino UNO
- LCD display
- Gas sensor
- Load cell
- Relay
- GSM modem
- RF transmitter and receiver
- DC motor
- Gas valve
- Generator

4.2.1 Arduino Uno

Arduino/Genuine Uno is a microcontroller board based on the Atmega328. It has 14 digital input/output pins (of which 6 can be used as PWM outputs), 6 analog inputs, a 16 MHz quartz crystal, a USB connection, a power jack, an ICSP header and a reset button. It contains everything needed to support the microcontroller; simply connect it to a computer with a USB cable or power it with a AC-to-DC adapter or battery to get started. You can tinker with your UNO without worrying too much about doing something wrong, worst case scenario you can replace the chip for a few dollars and start over again.

Figure 4.1 Pin diagram of Arduino Uno

"Uno" means one in Italian and was chosen to mark the release of Arduino Software (IDE) 1.0. The Uno board and version 1.0 of Arduino Software (IDE) were the reference versions of Arduino, now evolved to newer releases. The Uno board is the first in a series of USB Arduino boards, and the reference model for the Arduino platform; for an extensive list of current, past or outdated boards see the Arduino index of boards.

Table 4.1 Technical specs

Microcontroller	ATmega328P
Operating Voltage	5V
Input Voltage (recommended)	7-12V
Input Voltage (limit)	6-20V
Digital I/O Pins	14 (of which 6 provide PWM output)
PWM Digital I/O Pins	6
Analog Input Pins	6
DC Current per I/O Pin	20 mA
DC Current for 3.3V Pin	50 mA
Flash Memory	32 KB (ATmega328P) of which 0.5 KB used by bootloader
SRAM	2 KB (ATmega328P)
EEPROM	1 KB (ATmega328P)
Clock Speed	16 MHz

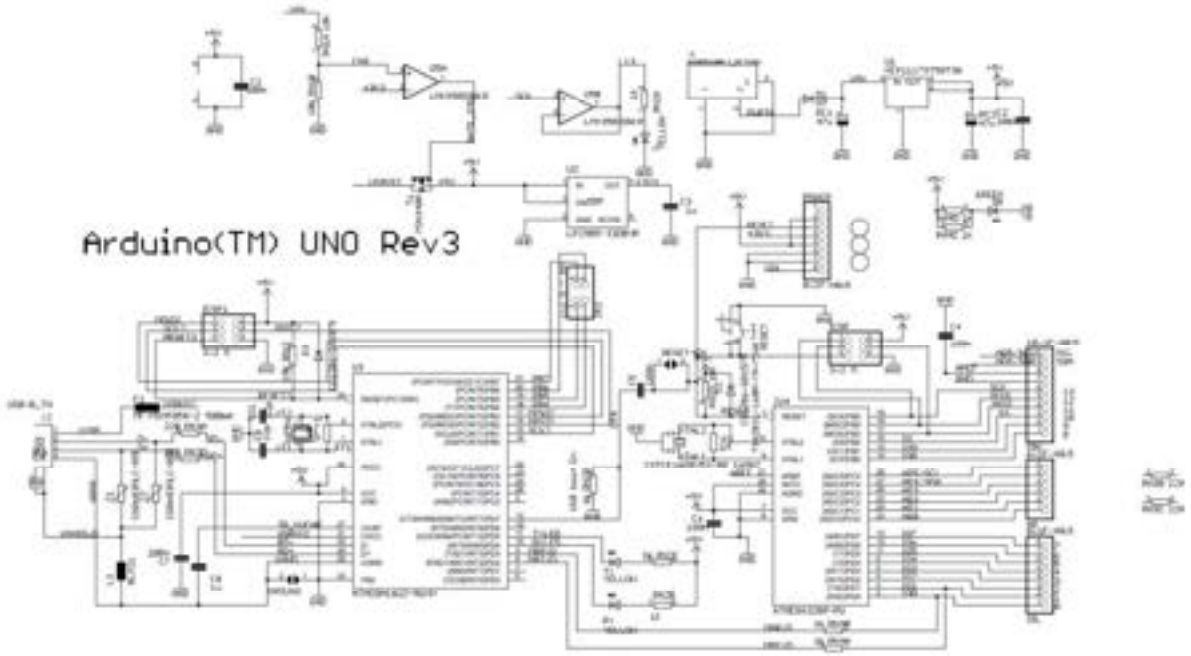

Figure 4.2 Circuit diagram for Arduino UNO

Power

The Arduino/Genuine Uno board can be powered via the USB connection or with an external power supply. The power source is selected automatically.

External (non-USB) power can come either from an AC-to-DC adapter (wall-wart) or battery. The adapter can be connected by plugging a 2.1mm center-positive plug into the board's power jack. Leads from a battery can be inserted in the GND and Vin pin headers of the POWER connector.

The board can operate on an external supply from 6 to 20 volts. If supplied with less than 7V, however, the 5V pin may supply less than five volts and the board may become unstable. If using more than 12V, the voltage regulator may overheat and damage the board. The recommended range is 7 to 12 volts.The power pins are;

- Vin. The input voltage to the Arduino/Genuine board when it's using an external power source (as opposed to 5 volts from the USB connection or other regulated power source). You can supply voltage through this pin, or, if supplying voltage via the power jack, access it through this pin.

- 5V.This pin outputs a regulated 5V from the regulator on the board. The board can be supplied with power either from the DC power jack (7 - 12V), the USB connector (5V), or the VIN pin of the board (7-12V). Supplying voltage via the 5V or 3.3V pins bypasses the regulator, and can damage your board. We don't advise it.
- 3V3. A 3.3 volt supply generated by the on-board regulator. Maximum current draw is 50 mA.
- GND. Ground pins.
- IOREF. This pin on the Arduino/Genuine board provides the voltage reference with which the microcontroller operates. A properly configured shield can read the IOREF pin voltage and select the appropriate power source or enable voltage translators on the outputs to work with the 5V or 3.3V.

Memory

The ATmega328 has 32 KB (with 0.5 KB occupied by the bootloader). It also has 2 KB of SRAM and 1 KB of EEPROM (which can be read and written with the EEPROM library).

Input and Output

See the mapping between Arduino pins and ATmega328P ports. The mapping for the Atmega8, 168, and 328 is identical.

Each of the 14 digital pins on the Uno can be used as an input or output, using pinMode(),digitalWrite(), and digitalRead() functions. They operate at 5 volts. Each pin can provide or receive 20 mA as recommended operating condition and has an internal pull-up resistor (disconnected by default) of 20-50k ohm. A maximum of 40mA is the value that must not be exceeded on any I/O pin to avoid permanent damage to the microcontroller.

- Serial: 0 (RX) and 1 (TX). Used to receive (RX) and transmit (TX) TTL serial data. These pins are connected to the corresponding pins of the ATmega8U2 USB-to-TTL Serial chip.
- External Interrupts: 2 and 3. These pins can be configured to trigger an interrupt on a low value, a rising or falling edge, or a change in value. See the attachInterrupt() function for details.
- PWM: 3, 5, 6, 9, 10, and 11. Provide 8-bit PWM output with the analogWrite() function.

- SPI: 10 (SS), 11 (MOSI), 12 (MISO), 13 (SCK). These pins support SPI communication using the SPI library.
- LED: 13. There is a built-in LED driven by digital pin 13. When the pin is HIGH value, the LED is on, when the pin is LOW, it's off.
- TWI: A4 or SDA pin and A5 or SCL pin. Support TWI communication using the Wire library.

The Uno has 6 analog inputs, labeled A0 through A5, each of which provide 10 bits of resolution (i.e. 1024 different values). By default they measure from ground to 5 volts, though is it possible to change the upper end of their range using the AREF pin and the analog reference() function.

There are a couple of other pins on the board:

- AREF. Reference voltage for the analog inputs. Used with analog reference( ).
- Reset. Bring this line LOW to reset the microcontroller. Typically used to add a reset button to shields which block the one on the board.

Communication

Arduino/Genuine Uno has a number of facilities for communicating with a computer, another Arduino/Genuine board, or other microcontrollers. The ATmega328 provides UART TTL (5V) serial communication, which is available on digital pins 0 (RX) and 1 (TX). An ATmega16U2 on the board channels this serial communication over USB and appears as a virtual com port to software on the computer. The 16U2 firmware uses the standard USB COM drivers, and no external driver is needed. However, on Windows, a .inf file is required. The Arduino Software (IDE) includes a serial monitor which allows simple textual data to be sent to and from the board. The RX and TX LEDs on the board will flash when data is being transmitted via the USB-to-serial chip and USB connection to the computer (but not for serial communication on pins 0 and 1).

A Software Serial library allows serial communication on any of the Uno's digital pins.

The ATmega328 also supports I2C (TWI) and SPI communication. The Arduino Software (IDE) includes a Wire library to simplify use of the I2C bus; see the documentation for details. For SPI communication, use the SPI library.

Automatic (Software) Reset

Rather than requiring a physical press of the reset button before an upload, the Arduino/Genuine Uno board is designed in a way that allows it to be reset by software running on a connected computer. One of the hardware flow control lines (DTR) of the ATmega8U2/16U2 is connected to the reset line of the ATmega328 via a 100 nanofarad capacitor. When this line is asserted (taken low), the reset line drops long enough to reset the chip. The Arduino Software (IDE) uses this capability to allow you to upload code by simply pressing the upload button in the interface toolbar. This means that the bootloader can have a shorter timeout, as the lowering of DTR can be well-coordinated with the start of the upload.

This setup has other implications. When the Uno is connected to either a computer running Mac OS X or Linux, it resets each time a connection is made to it from software (via USB). For the following half-second or so, the bootloader is running on the Uno. While it is programmed to ignore malformed data (i.e. anything besides an upload of new code), it will intercept the first few bytes of data sent to the board after a connection is opened. If a sketch running on the board receives one-time configuration or other data when it first starts, make sure that the software with which it communicates waits a second after opening the connection and before sending this data.

The Uno board contains a trace that can be cut to disable the auto-reset. The pads on either side of the trace can be soldered together to re-enable it. It's labeled "RESET-EN". You may also be able to disable the auto-reset by connecting a 110 ohm resistor from 5V to the reset line; see this forum thread for details.

Revisions

Revision 3 of the board has the following new features:

- 1.0 pinout: added SDA and SCL pins that are near to the AREF pin and two other new pins placed near to the RESET pin, the IOREF that allow the shields to adapt to the voltage provided from the board. In future, shields will be compatible with both the board that uses the AVR, which operates with 5V and with the Arduino Due that operates with 3.3V. The second one is a not connected pin, that is reserved for future purposes.
- Stronger RESET circuit.

4.2.2 LCD Display

Figure 4.3 LCD Display

A **liquid crystal display** (**LCD**) is a thin, flat electronic visual display that uses the light modulating properties of liquid crystals (LCs). LCs do not emit light directly.

They are used in a wide range of applications including: computer monitors, television, instrument panels, aircraft cockpit displays, signage, etc. They are common in consumer devices such as video players, gaming devices, clocks, watches, calculators, and telephones. LCDs have displaced cathode ray tube(CRT) displays in most applications.

They are usually more compact, lightweight, portable, less expensive, more reliable, and easier on the eyes. They are available in a wider range of screen sizes than CRT and plasma displays, and since they do not use phosphors, they cannot suffer image burn-in.LCD's are more energy efficient and offer safer disposal than CRTs. Its low electrical power consumption enables it to be used in battery-powered electronic equipment. It is an electronically-modulated optical device made up of any number of pixels filled with liquid crystals and arrayed in front of a light source (backlight) or reflector to produce images in colour or monochrome. The earliest discovery leading to the development of LCD technology, the discovery of liquid crystals, dates from 1888. By 2008, worldwide sales of televisions with LCD screens had surpassed the sale of CRT units.

4.2.3 GAS Sensors

Electrochemical gas sensors are gas detectors that measure the concentration of a target gas by oxidizing or reducing the target gas at an electrode and measuring the resulting current.

Figure 4.4 Gas sensor

Construction

The sensors contain two or three electrodes, occasionally four, in contact with an electrolyte. The electrodes are typically fabricated by fixing a high surface area precious metal on to the porous hydrophobic membrane. The working electrode contacts both the electrolyte and the ambient air to be monitored usually via a porous membrane. The electrolyte most commonly used is a mineral acid, but organic electrolytes are also used for some sensors. The electrodes and housing are usually in a plastic housing which contains a gas entry hole for the gas and electrical contacts.

Theory of operation

The gas diffuses into the sensor, through the back of the porous membrane to the working electrode where it is oxidized or reduced. This electrochemical reaction results in an electric current that passes through the external circuit. In addition to measuring,

amplifying and performing other signal processing functions, the external circuit maintains the voltage across the sensor between the working and counter electrodes for a two electrode sensor or between the working and reference electrodes for a three electrode cell. At the counter electrode an equal and opposite reaction occurs, such that if the working electrode is an oxidation, then the counter electrode is a reduction.

Diffusion controlled response

The magnitude of the current is controlled by how much of the target gas is oxidized at the working electrode. Sensors are usually designed so that the gas supply is limited by diffusion and thus the output from the sensor is linearly proportional to the gas concentration. This linear output is one of the advantages of electrochemical sensors over other sensor technologies, (e.g. infrared), whose output must be linearized before they can be used. A linear output allows for more precise measurement of low concentrations and much simpler calibration (only baseline and one point are needed).

Diffusion control offers another advantage. Changing the diffusion barrier allows the sensor manufacturer to tailor the sensor to a particular target gas concentration range. In addition, since the diffusion barrier is primarily mechanical, the calibration of electrochemical sensors tends to be more stable over time and so electrochemical sensor based instruments require much less maintenance than some other detection technologies. In principle, the sensitivity can be calculated based on the diffusion properties of the gas path into the sensor, though experimental errors in the measurement of the diffusion properties make the calculation less accurate than calibrating with test gas.[1]

Cross sensitivity

For some gases such as ethylene oxide, cross sensitivity can be a problem because ethylene oxide requires a very active working electrode catalyst and high operating potential for its oxidation. Therefore gases which are more easily oxidized such as alcohols and carbon monoxide will also give a response. Cross sensitivity problems can be eliminated though through the use of a chemical filter, for example filters that allows the target gas to pass through unimpeded, but which reacts with and removes common interferences.

While electrochemical sensors offer many advantages, they are not suitable for every gas. Since the detection mechanism involves the oxidation or reduction of the gas, electrochemical sensors are usually only suitable for gases which are electrochemically active, though it is possible to detect electrochemically inert gases indirectly if the gas interacts with another species in the sensor that then produces a response.[2] Sensors for carbon dioxide are an example of this approach and they have been commercially available for several years.

4.2.4 Load Cell

Load cell is a transducer that is used to convert a force into electrical signal. This conversion is indirect and happens in two stages. Through a mechanical arrangement, the force being sensed deforms a strain gauge. The strain gauge converts the deformation (strain) to electrical signals. A load cell usually consists of four strain gauges in a Wheatstone bridge configuration. Load cells of one strain gauge (quarter bridge) or two strain gauges (half bridge) are also available. The electrical signal output is typically in the order of a few mill volts and requires amplification by an instrumentation amplifier before it can be used. The output of the transducer is plugged into an algorithm to calculate the force applied to the transducer.

Although strain gauge load cells are the most common, there are other types of load cells as well. In industrial applications, hydraulic (or hydrostatic) is probably the second most common, and these are utilized to eliminate some problems with strain gauge load cell devices. As an example, a hydraulic load cell is immune to transient voltages (lightning) so might be a more effective device in outdoor environments.

Other types include piezoelectric load cells (useful for dynamic measurements of force), and vibrating wire load cells, which are useful in geo mechanical applications due to low amounts of drift.

Every load cell is subject to "ringing" when subjected to abrupt load changes. This stems from the spring-like behavior of load cells. In order to measure the loads, they have to deform. As such, a load cell of finite stiffness must have spring-like behavior, exhibiting vibrations at its natural frequency. An oscillating data pattern can be the result of ringing. Ringing can be suppressed in a limited fashion by passive means. Alternatively, a control

system can use an actuator to actively damp out the ringing of a load cell. This method offers better performance at a cost of significant increase in complexity

4.2.5 GSM

A digital communication system used for mobile technology is the Global System for Mobile Communication (GSM), which is the most popular standard for mobile phones today. The GSM system transmits the digital information through the atmosphere by conveying the information to an analog waveform. The GSM Receiver is used to receive the digital data in remote area from work place. The digital data contains information about various parameters measured by the sensors in the work place. A GSM transmitter module is used at the transmitter side which is connected to the PIC controller and a GSM receiving module like mobile phone is used to receive the digital information in remote area.

A GSM modem is a specialized type of modem which accepts a SIM card, and operates over a subscription to a mobile operator, just like a mobile phone. From the mobile operator perspective, a GSM modem looks just like a mobile phone.

For the purpose of this document, the term GSM modem is used as a generic term to refer to any modem that supports one or more of the protocols in the GSM evolutionary family, including the 2.5G technologies GPRS and EDGE, as well as the 3G technologies WCDMA, UMTS, HSDPA and HSUPA.

A GSM modem exposes an interface that allows applications such as nowSMS to send and receive messages over the modem interface. The mobile operator charges for this message sending and receiving as if it was performed directly on a mobile phone. To perform these tasks, a GSM modem must support an "extended AT command set" for sending/receiving SMS messages, as defined in the ETSI GSM 07.05 and and 3GPP TS 27.005 specifications.

A GSM modem can be a dedicated modem device with a serial, USB or Bluetooth connection, such as the Falcom Samba 75 used in this document. (Other manufacturers of dedicated GSM modem devices include Wavecome, Multitech and

iTegno.) To begin, insert a GSM SIM card into the modem and connect it to an available USB port on your computer.

Any phone that supports the "extended AT command set" for sending/receiving SMS messages, as defined in ETSI GSM 07.05 and/or 3GPP TS 27.005, can be supported by the Now SMS & MMS Gateway. Note that not all mobile phones support this modem interface.

Due to some compatibility issues that can exist with mobile phones, using a dedicated GSM modem is usually preferable to a GSM mobile phone. This is more of an issue with MMS messaging, where if you wish to be able to receive inbound MMS messages with the gateway, the modem interface on most GSM phones will only allow you to send MMS messages. This is because the mobile phone automatically processes received MMS message notifications without forwarding them via the modem interface.

It should also be noted that not all phones support the modem interface for sending and receiving SMS messages. In particular, most smart phones, including Blackberries, iPhone, and Windows Mobile devices, do not support this GSM modem interface for sending and receiving SMS messages at all at all. Additionally, Nokia phones that use the S60 (Series 60) interface, which is Symbian based, only support sending SMS messages via the modem interface, and do not support receiving SMS via the modem interface.

When you install your GSM modem, or connect your GSM mobile phone to the computer, be sure to install the appropriate Windows modem driver from the device manufacturer. To simplify configuration, the Now SMS & MMS Gateway will communicate with the device via this driver. If a Windows driver is not available for your modem, you can use either the "Standard" or "Generic" 33600 bps modem driver that is built into windows. A benefit of utilizing a Windows modem driver is that you can use Windows diagnostics to ensure that the modem is communicating properly with the computer.

The Now SMS & MMS gateway can simultaneously support multiple modems, provided that your computer hardware has the available communications port resources.

4.2.6 Relay

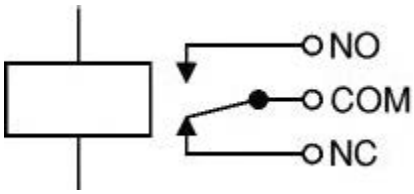
A relay is an electrically operated switch. Current flowing through the coil of the relay creates a magnetic field which attracts a lever and changes the switch contacts. The coil current can be on or off so relays have two switch positions and they are double throw (changeover) switches. Relays allow one circuit to switch a second circuit which can be completely separate from the first. For example a low voltage battery circuit can use a relay to switch a 230V AC mains circuit. There is no electrical connection inside the relay between the two circuits; the link is magnetic and mechanical.

The coil of a relay passes a relatively large current, typically 30mA for a 12V relay, but it can be as much as 100mA for relays designed to operate from lower voltages. Most ICs (chips) cannot provide this current and a transistor is usually used to amplify the small IC current to the larger value required for the relay coil. The maximum output current for the popular 555 timer IC is 200mA so these devices can supply relay coils directly without amplification.

Figure 4.5 Relay

Relays are usually SPDT or DPDT but they can have many more sets of switch contacts, for example relays with 4 sets of changeover contacts are readily available. Most relays are designed for PCB mounting but you can solder wires directly to the pins providing you take care to avoid melting the plastic case of the relay. The animated picture shows a working relay with its coil and switch contacts. You can see a

lever on the left being attracted by magnetism when the coil is switched on. This lever moves the switch contacts. There is one set of contacts (SPDT) in the foreground and another behind them, making the relay DPDT.



The relay's switch connections are usually labeled COM, NC and NO:

- **COM** = Common, always connect to this, it is the moving part of the switch.
- **NC** = Normally Closed, COM is connected to this when the relay coil is **off**.
- **NO** = Normally Open, COM is connected to this when the relay coil is **on**.

4.2.7 ALARM CIRCUIT

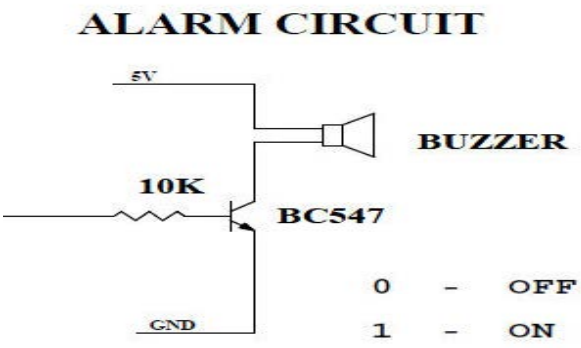


Figure 4.6 Circuit diagram of Alarm circuit.

Circuit description

The circuit is designed to control the buzzer. The buzzer ON and OFF is controlled by the NPN transistor (BC 547). The buzzer is connected in the transistor collector terminal.

When high pulse signal is given to base of the transistors it will be turned on and now alarm get ground so it will be on.

If low pulse is given to the NPN transistor base means it will be off and also alarm goes to the off state.

Table 4.2 Voltage Signal from Microcontroller

Voltage Signal from Microcontroller or PC	Transistor	Buzzer
1	ON	ON
0	OFF	OFF

4.2.8 Encoder and Decoder

An encoder is a device, circuit, transducer, software program, algorithm or person that converts information from one format or code to another, for the purposes of standardization, speed, secrecy, security, or saving space by shrinking size.

A decoder is a device which does the reverse of an encoder, undoing the encoding so that the original information can be retrieved. The same method used to encode is usually just reversed in order to decode.

In digital electronics, a decoder can take the form of a multiple-input, multiple-output logic circuit that converts coded inputs into coded outputs, where the input and output codes are different. e.g. n-to-2^n, binary-coded decimal decoders. Enable inputs must be on for the decoder to function, otherwise its outputs assume a single "disabled" output code word. Decoding is necessary in applications such as data multiplexing, 7 segment display and memory address decoding.

The example decoder circuit would be an AND gate because the output of an AND gate is "High" (1) only when all its inputs are "High." Such output is called as "active High output". If instead of AND gate, the NAND gate is connected the output will be "Low" (0) only when all its inputs are "High". Such output is called as "active low output".

A slightly more complex decoder would be the n-to-2^n type binary decoders. These type of decoders are combinational circuits that convert binary information from 'n'

coded inputs to a maximum of 2^n unique outputs. We say a *maximum* of 2^n outputs because in case the 'n' bit coded information has unused bit combinations, the decoder may have less than 2^n outputs. We can have 2-to-4 decoder, 3-to-8 decoder or 4-to-16 decoder. We can form a 3-to-8 decoder from two 2-to-4 decoders (with enable signals).

Similarly, we can also form a 4-to-16 decoder by combining two 3-to-8 decoders. In this type of circuit design, the enable inputs of both 3-to-8 decoders originate from a 4th input, which acts as a selector between the two 3-to-8 decoders. This allows the 4th input to enable either the top or bottom decoder, which produces outputs of D(0) through D(7) for the first decoder, and D(8) through D(15) for the second decoder.

A decoder that contains enable inputs is also known as a decoder-demultiplexer. Thus, we have a 4-to-16 decoder produced by adding a 4th input shared among both decoders, producing 16 outputs.

4.2.9 RF Transmitter Receiver

Radio frequency (RF) radiation is a subset of electromagnetic radiation with a wavelength of 100km to 1mm, which is a frequency of 3 KHz to 300 GHz,[1] respectively. This range of electromagnetic radiation constitutes the spectral corresponds to the frequency of alternating current electrical signals used to produce and detect radio waves. RF can refer to electromagnetic oscillations in either electrical circuits or radiation through air and space. Like other subsets of electromagnetic radiation, RF travels at the speed of light.

Radio communication

In order to receive radio signals, for instance from AM/FM radio stations, a radio antenna must be used. However, since the antenna will pick up thousands of radio signals at a time, a radio tuner is necessary to tune in to a particular frequency (or frequency range). This is typically done via a resonator (in its simplest form, a circuit with a capacitor and an inductor). The resonator is configured to resonate at a particular frequency (or frequency band), thus amplifying sine waves at that radio frequency, while d

ignoring other sine waves. Usually, either the inductor or the capacitor of the resonator is adjustable, allowing the user to change the frequency at which it resonates.

Special properties of RF electrical signals

Electrical currents that oscillate at RF have special properties not shared by direct current signals. One such property is the ease with which they can ionize air to create a conductive path through air. This property is exploited by 'high frequency' units used in electric arc welding, although strictly speaking these machines do not typically employ frequencies within the HF band. Another special property is an electromagnetic force that drives the RF current to the surface of conductors, known as the skin effect. Another property is the ability to appear to flow through paths that contain insulating material, like the dielectric insulator of a capacitor. The degree of effect of these properties depends on the frequency of the signals.

Radio spectrum

Radio spectrum refers to the part of the electromagnetic spectrum corresponding to radio frequencies – that is, frequencies lower than around 300 GHz (or, equivalently, wavelengths longer than about 1 mm).

Different parts of the radio spectrum are used for different radio transmission technologies and applications. Radio spectrum is typically government regulated in developed countries, and in some cases is sold or licensed to operators of private radio transmission systems (for example, cellular telephone operators or broadcast television stations). Ranges of allocated frequencies are often referred to by their provisioned use (for example, cellular spectrum or television spectrum)

Notes

- Above 300 GHz, the absorption of electromagnetic radiation by Earth's atmosphere is so great that the atmosphere is effectively opaque, until it becomes transparent again in the infrared and optical window frequency ranges.

- The ELF, SLF, ULF, and VLF bands overlap the AF (audio frequency) spectrum, which is approximately 20–20,000 Hz. However, sounds are transmitted by atmospheric compression and expansion, and not by electromagnetic energy.
- The SHF and EHF bands are sometimes not considered to be a part of the radio spectrum, forming their own microwave spectrum.

4.2.10 Power Supplies

4.2.10.1 Introduction

The present chapter introduces the operation of power supply circuits built using filters, rectifiers, and then voltage regulators. Starting with an ac voltage, a steady dc voltage is obtained by rectifying the ac voltage, then filtering to a dc level, and finally, regulating to obtain a desired fixed dc voltage. The regulation is usually obtained from an IC voltage regulator unit, which takes a dc voltage and provides a somewhat lower dc voltage, which remains the same even if the input dc voltage varies, or the output load connected to the dc voltage changes.

A block diagram containing the parts of a typical power supply and the voltage at various points in the unit is shown in fig 19.1. The ac voltage, typically 120 V rms, is connected to a transformer, which steps that ac voltage down to the level for the desired dc output. A diode rectifier then provides a full-wave rectified voltage that is initially filtered by a simple capacitor filter to produce a dc voltage. This resulting dc voltage usually has some ripple or ac voltage variation. A regulator circuit can use this dc input to provide a dc voltage that not only has much less ripple voltage but also remains the same dc value even if the input dc voltage varies somewhat, or the load connected to the output dc voltage changes. This voltage regulation is usually obtained using one of a number of popular voltage regulator IC units.

4.2.10.2 Voltage Regulator

Voltage regulators comprise a class of widely used ICs. Regulator IC units contain the circuitry for reference source, comparator amplifier, control device, and overload protection all in a single IC. Although the internal construction of the IC is somewhat different from that described for discrete voltage regulator circuits, the external

operation is much the same. IC units provide regulation of either a fixed positive voltage, a fixed negative voltage, or an adjustably set voltage.

A power supply can be built using a transformer connected to the ac supply line to step the ac voltage to a desired amplitude, then rectifying that ac voltage, filtering with a capacitor and RC filter, if desired, and finally regulating the dc voltage using an IC regulator. The regulators can be selected for operation with load currents from hundreds of milli amperes to tens of amperes, corresponding to power ratings from milliwatts to tens of watts.

4.2.10.3 Three Terminal Voltage Regulator

Fig shows the basic connection of a three-terminal voltage regulator IC to a load. The fixed voltage regulator has an unregulated dc input voltage, Vi, applied to one input terminal, a regulated output dc voltage, Vo, from a second terminal, with the third terminal connected to ground. For a selected regulator, IC device specifications list a voltage range over which the input voltage can vary to maintain a regulated output voltage over a range of load current.

Fixed Positive Voltage Regulators:

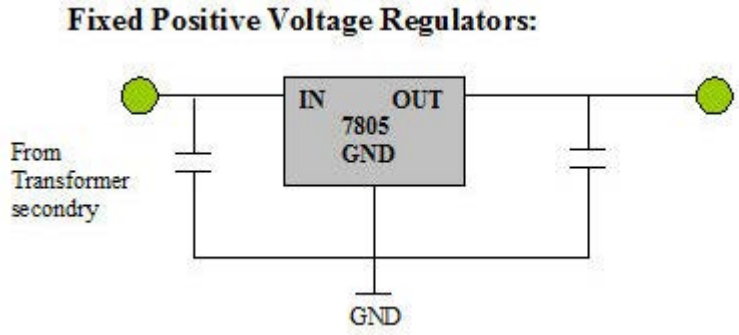

Figure 4.7 Fixed Positive Voltage Regulators

The series 78 regulators provide fixed regulated voltages from 5 to 24 V. Figure 19.26 shows how one such IC, a 7812, is connected to provide voltage regulation with output from this unit of +12V dc. An unregulated input voltage Vi is filtered by capacitor C1 and connected to the IC's IN terminal. The IC's OUT terminal provides a regulated + 12V which is filtered by capacitor C2 (mostly for any high-frequency noise).

The third IC terminal is connected to ground (GND). These limitations are spelled out in the manufacturer's specification sheets.

Positive Voltage Regulators in 7800 series

Table 4.3 Positive Voltage Regulators in 7800

IC Part	**Output Voltage (V)**	**Minimum Vi (V)**
7805	+5	7.3
7806	+6	8.3
7808	+8	10.5
7810	+10	12.5
7812	+12	14.6

CHAPTER 5

RESULT AND DISCUSSIONS

In Arduino Based gas Monitoring and Automatic Cylinder booking with notification System gas sensor, 10 kg stack cell as info gadgets and relay, 16x2 LCD show and GSM Terminal utilized as yield gadgets.

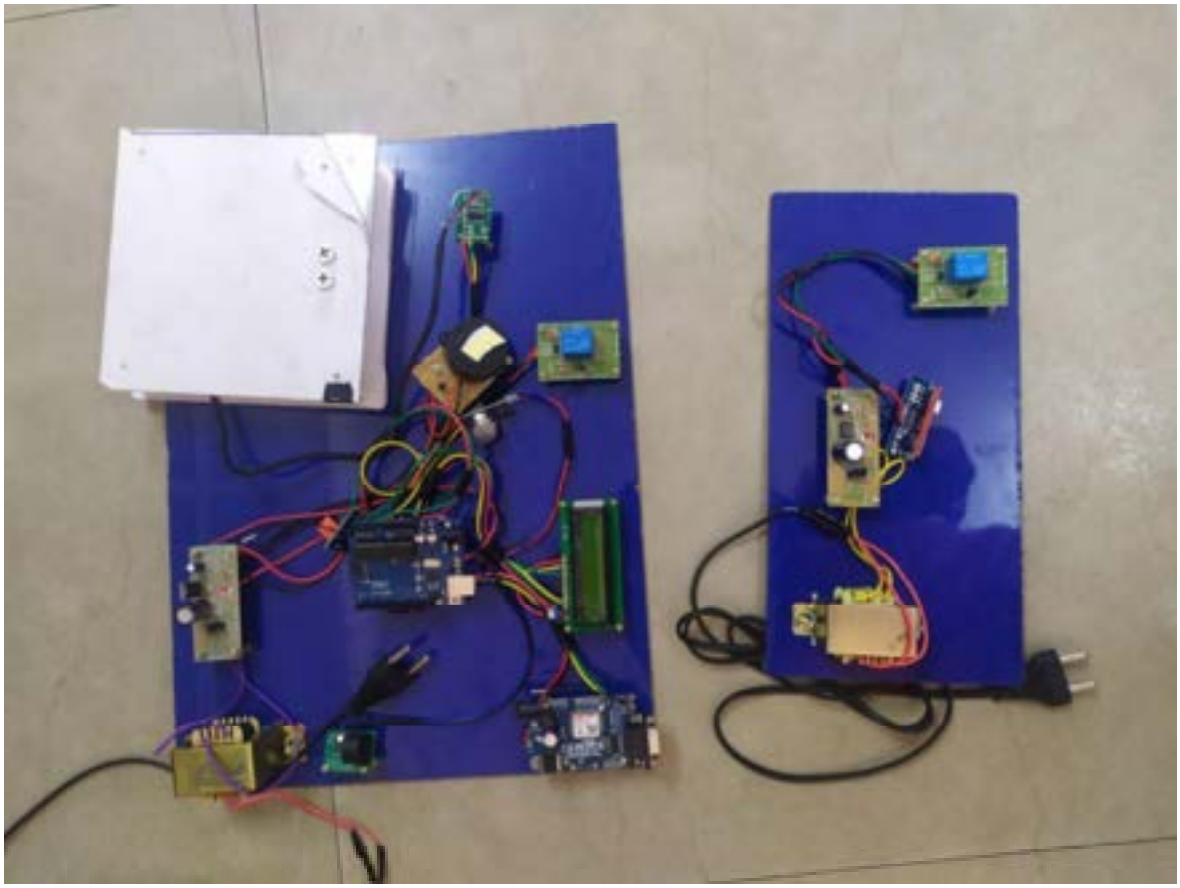

Figure 5.1 A Microcontroller Based LPG Cylinder Booking and Leakage Detection Using GSM

CHAPTER 6

CONCLUSION AND FUTURE ENHANCEMENT

6.1 CONCLUSION

In this paper we have used automatic gas booking with alert system without human intervention. Our system helps customers to upgrade their safety and protect life and property from reputed accidents. The main objective of our system is to measure the gas present in cylinder when the weight of cylinder is below the fixed load by using weight sensor. The gas agency gets the order of new cylinder and owner received the messages regarding the status .Thus the system developed by us will somehow help the LPG Gas consumer to lead a safety life and comfortable life

6.2 FUTURE ENHANCEMENT

Future Scope This monitoring system can be further enhanced by using Ethernet in place Bluetooth module in order to operate from anywhere, which supports the another real-time application. For industrial purposes , robot can be developed for detecting multiple gas concentrations and fire. Instead of load cell sensor we can also be used as pressure sensor which detects the amount of gas in the cylinder and also detects pressure of gas in cylinder pipe, alerting owner via call and Monitoring by using Android device from any remote location.

ABSTRACT

Gas leakage is a major problem with industrial sector and also home applications etc. To avoid the gas leakage is to install a gas leakage detection system at the society. The main aim of this project is used to design that can automatically gas booking system, gas leakage detection system, alert system and control gas leakage. LPG cylinders have become an integral part of every home. Our kitchens are occupied with LPG cylinders which is used to make delicious food. But it can be very dangerous to make problems in our life. The aim of this project is to design a safety-oriented system which will alert the user about any problem in the kitchen through mobile by using GSM and give the buzzer sound by using alert system. This system will detect the gas leakage of LPG and send an alert information to the user, at the same time it will switch off the gas supply of LPG by switching regulator-switch using BO(Battery Operating) motor. It is also used to monitoring the high voltage passing through the home appliances and also industrial sector it will used to reduce the voltage level in the power supply. It also measures safety from any gas leakage accident like explosion. In additional advantage, this system has a load cell used to continuously monitoring the cylinder weight and send information to the user. The project is very helpful to check the entire LPG cylinder booking procedure automated Without human intervention and also Automated cylinder booking we also designed feature related to the safety to the user. And also the LPG Cylinders are produced some heat energy. The heat energy is generating the power by using generator through exhaust fan.

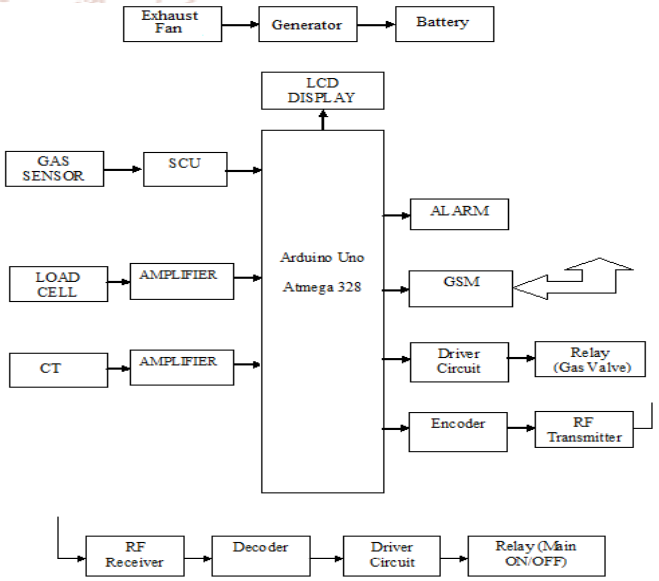
INTRODUCTION

Liquefied petroleum gas is used for industrial applications and domestic purposes. It has a smoke less gassing system. The main constituents of LPG are propane and butane. Gas leakage is a major problem in a residential houses and create fundamental issue on the society. Fire accidents mainly occur due to technical fault on the cylinder. A better systems on need to reduce the accident due to gas leakage. LPG gas is more higher sensitivity compared to gas is present in the air. The weight of the cylinder is continuously measured by load cell and the information is convey to the user by using GSM. The gas leakage is detected by the electro chemical cell and give the buzzer sound and convey the information to the user. The main objective of the project is used to reduce the voltage level in the main power supply. It is used to identify the any short circuit present in the industrial domain and also home appliances.

PROPOSED APPROACH

In proposed system, which is used to measure the LPG gas cylinder weight. When it goes lower level it will intimate to the user through mobile phone automatically. And it will also sense the gas leakage present in the home in addition to its if the gas leakage present in home it will automatically drop the voltage level in the main supply.

BLOCK DIAGRAM



GAS SENSOR

A gas sensor is a device which is used to detect the presence of gases in the atmosphere. In this we have use the electrochemical sensor. The construction of the gas sensor is Gas sensor layer, Heater coil, Electrode Line, Tubular ceramic, Electrode.

Gas sensor: It is used to sensing the gas, the sensing element is made up of Tin dioxide (sno2).

Heater coil: It is made up of Nickel chromium which has high melting point so that it can stay heated up without getting melted.

Features
1. High Sensitivity to LPG
2. Low Sensitivity to alcohol, Smoke.
3. Fast Response Time: <10s.

LCD DISPLAY

A Liquid crystal display is the flat panel display or other electronically modulated optical device. It does not emit the light directly. It consume less power when compare to LED and gas display. LCD is made up of millions of pixels.

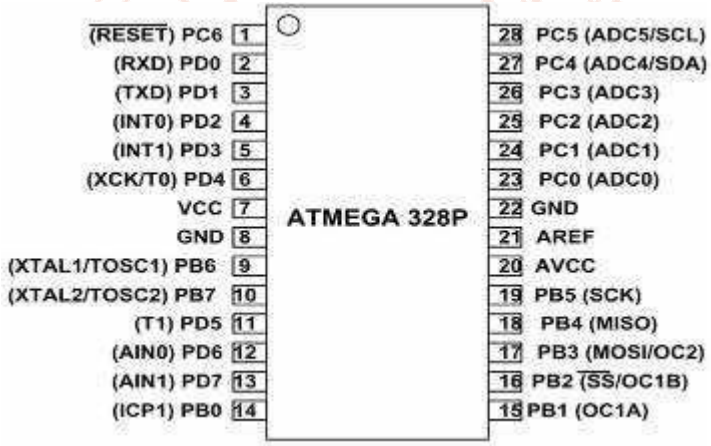
In here we can use the 16*2 display. It is mainly used to display the cylinder weight and current status of the cylinder

BUZZER

It is mainly used to indicate the gas leakage has occurred.

ATMEGA328

Arduino Uno is the 8-bit microcontroller. The microcontroller board is based on the ATmega328. It has 14 digital input pins and output pins and also have 6 analog pins and it has 16MHZ quartz crystal. AT mega memory has 1KB (EEPROM) Electrical Erasable Programmable Read Only Memory. The output voltage is 5V and input voltage is 7-12V. The clock speed is16 MHZ. We can use the IDE (Integrated circuit Environment) software. It is mainly used to allow to write the software and also uploaded on the board. A program written with the IDE for the board is called as sketch.



GSM MODULE

GSM (Global System for Mobile communication) it is a digital mobile network. It is mainly used in mobile phones. GSM phone can sent and receive the data packet while making call.GSM mainly used to transfer the message to mobile phone. It operated at frequency either 900MHZ, 1800MHZ. The system transmits the digital information through atmosphere and convert in to analog waveform.

DRIVER CIRCUIT

It is circuit or components used to control any another circuit or components, such as high power transistor, liquid crystal display. It also control the current flow of the system.

RELAY

Relay is also called as switch. Relay that open and close circuit electromechanically or electronically. Relay are widely used to switch starting coil.

LOAD CELL

Load cell is the type of transducer. It convert force such as tension, compression, pressure or torque into an electrical signal. The load cell is mainly used measure the cylinder weight and also monitoring every day.

RESULT AND DISCUSSION

In this system is used to detect the gas leakage and automatic gas booking system. Electro chemical sensor is used to sense the gas leakage and give alert to the user by using mobile and also buzzer system. The information is displayed on the LCD display in the mobile devices. And also the system is used to reduce the voltage level in the main power supply and it will identify any high voltage is possible to the home appliances and industrial side. This system is very simple and reliable.

CONCLUSION

As we discussed about the microcontroller based LPG cylinder booking and leakage detection using GSM this will be verified. This project is very useful to prevent from fire accident and save the human life.

ABSTRACT

The main objective of this project to dispose the reject material properly and reduce the environmental impacts. In our project done by Tamilnadu Newsprint and Papers Limited (TNPL). This is a Deinking process (DIP). Deinking process is the one in which the ink from the office waste and newspaper and removed in order to prevent it from dispersion into the pulp sodium soap is used for removing the ink. The sodium soap produced in conveyer. The existing method have only one conveyer. It carries the reject material and it create the environmental hazards. But our proposed method has two conveyers. These conveyers are worked with the help of DCS. It reduces the environmental pollution and reduce the need for more manual labour. The conveyer 1 has a magnetic separator which separate the metal, iron and its components. The conveyer 2 has a reject material like polythene and reject material. Those materials are conveyed Baling machine by using the conveyer 2. Finally, these reject materials are bundled with the help of baling machine.

CHAPTER 1

INTRODUCTION

1.1 Introduction

A distributed control system (DCS) refers to a control system usually of a manufacturing system, process or any kind of dynamic system, in which the controller elements are not central in location (like the brain) but are distributed throughout the system with each component sub-system controlled by one or more controllers. The entire system of controllers is connected by networks for communication and monitoring. DCS is a very broad term used in a variety of industries, to monitor and control distributed equipment. Before the beginning of the DCS era there were pneumatic devices that controlled process and engineers manually turned valves on the site. Modeling of the systems was made possible by DCS as it allowed the ability to record and manages process from comfort of a computer screen. Because of DCS we are able to control processes remotely and gain a better understanding of how the process operate and how they can be improved to both increase safety and increase profit possibilities. The input modules receive information from input instruments in the process (or field) and transmit instructions to the output instruments in the field. Computer buses or electrical buses connect the processor and modules through multiplexer or demultiplexers. Buses also connect the distributed controllers with the central controller and finally to the Human–machine interface (HMI) or control consoles.

Figure 1.1 Image of DCS hardware

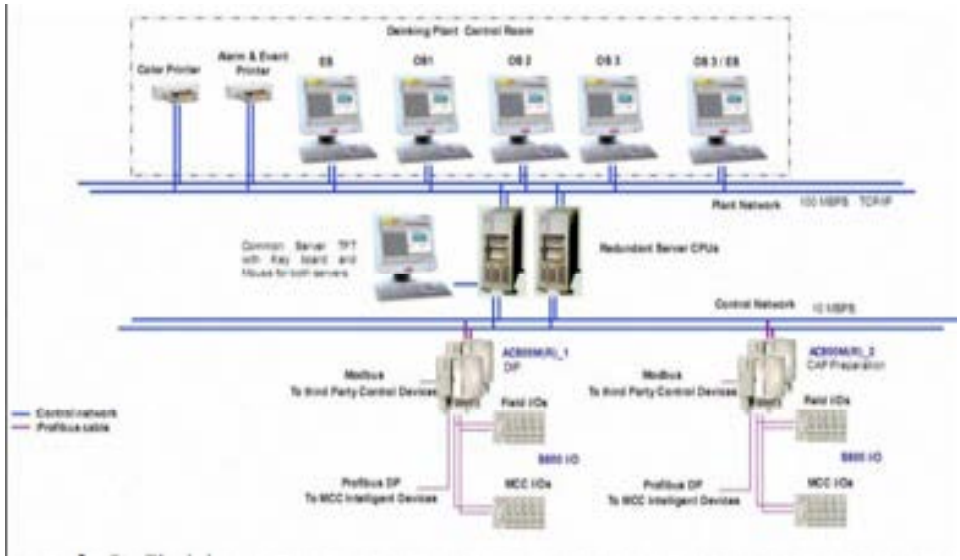

Figure 1.2 DCS structure

1.2 DCS vs PLC

DCS systems are deployed in operations where downtime due to a malfunction may cause material and personnel losses. To prevent them it's possible to include redundant solutions, with in turn are increasing the investments to the control system. Redundancy and sophisticated diagnostics are nowadays standard built-in options for DCS and it's not necessary for them to write a custom program. Downtime is related with online and offline application changes. A typical DCS runs non-stop for years.

In the case of DCS, the center for control is HMI because for the continuous control it's not possible to see the product (it's located in enclosed tangs, pipelines, ...) On the other hand in PLC control used for discrete control, the operator can see the product. Therefore, the operator must have as much information about the process on the screens to know to monitor and control it.

1.3 DCS application

Distributed control systems (DCSs) are dedicated systems used to control manufacturing processes that are continuous or batch-oriented, such as oil refining, petrochemicals, central station power generation, fertilizers, pharmaceuticals, food and beverage manufacturing, cement production, steelmaking, and papermaking. DCSs are connected to sensors and actuators and use setpoint control to control the flow of material through the plant. The most common example is a setpoint control loop consisting of a pressure sensor, controller, and control valve. Pressure or flow measurements are transmitted to the controller, usually through the aid of a signal conditioning input/output (I/O) device. Large oil refineries have many thousands of I/O points and employ very large DCSs.

1.4 Basic configuration of DCS system

There are many manufacturers that have designed and built distributed control systems (DCSs) with a large selection of features and enhancements to choose from. No matter what the control systems platform's structure is the tag name/point name implementation methodology is basically the same. There are some things that can be done before the actual plant implementation is done onsite to make this process more efficient. Once the necessary research and proper investigation of interface circuitry for field instruments is done, the configuration process is more reliable and cost-effective for the client-especially during a plant turnaround with time restraints.The control systems engineer is familiar with the software connections and the main DCS parts through the control system configuration. To understand what type of devices an engineer will be interfacing with, the following considerations are noted:

- **Hardwired inputs:** These physical wires make the connection between the DCS and the field. For example, the analog input signal by voltage, thermocouple type and resistance temperature device.
- **Other field devices such as control valves:** When considering the implementation of control valves, care must be given to the regulatory controller action inside the DCS whether the valves is a fail open or fail close type. The process and I&E engineers verify the information and pass it on to the control systems engineer for correct configuration of controllers.
- **Digital representation:** This is another signal represented by a square wave that is either high or low, on or off. They control the interactions of devices such as pumps, motor starters and solenoid valves. The I&E technician would have to know what device and circuitry to pass this information to the control systems engineer.
- **Tag name/point name configuration:**This configuration is the measuring boundaries that may also be known as 'process variable engineering unit low and process variable engineering unit high.' Based on process engineering and I&E technical information, a value should be determined and given to the control systems engineer.
- **Alarming values must be determined:**This will give the control system an indication that a trip valve has been reached. These valves are significant because this lets the process operator know what adjustments to make to keep the process in a safe condition and protect personnel and equipment.

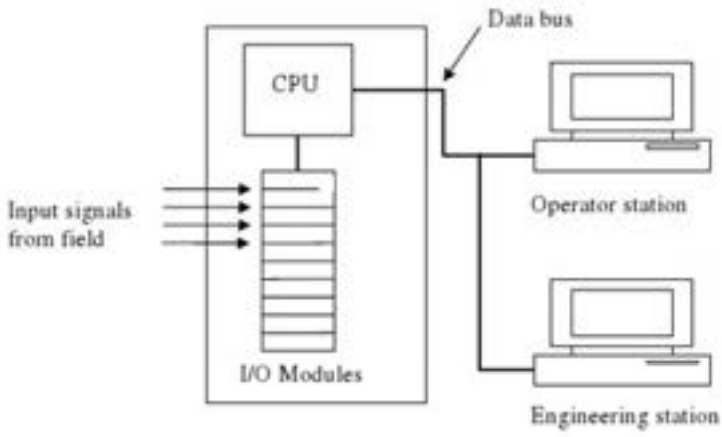

Figure 1.3 Basic configuration of DCS

1.5 Field Control Station (FCS)

It consists of input/output modules, CPU and Communication bus.The last evolution step of PAS which can be characterized as total functional and spatial distribution of functions for processing information is often designated as Field Control Systems(FCS). They are based on intelligent field devices and industrial digital communication systems used on field level(field bus).A series of points whose relative positions and elevations are known. These positions are used in basic data in mapping and charting.

1.6 Operator station

It is basically human interface machine with monitor, the operator man can view the process in the plant and check if any alarm is presents and he can change any setting, print reports..etc. Different station types are available to meet user needs. Experion Console Station is designed for control room operations in large process plants including refining, petrochemicals and mineral processing. Experion Flex Station is an option for less demanding or geographically distributed operations such as Pulp and Paper, Oil and Gas and pharmaceutical production. Flex Stations also support large number of users for casual access such as engineering or maintenance. Different Experion Station types can be used together on one system in any combination. Experion Console Stations can be grouped together to form a single operator workspace for process control and monitoring, event handling, alarm acknowledgement, alarm silencing and display manipulation. Flex stations share a pool of connections to allow a large number of casual users access to the system.Out of the box, state-of-the-art alarm management improves the operator's ability to minimize process interruptions and powerful trending allows the operator to maintain appropriate situational awareness and keep the process within desired limits. Group and detail displays are available to monitor and manage process variables. Configurable pull-down menus and toolbars allow easy, intuitive navigation and fast access to key process data.The HMIWeb solution pack library is available to quickly and efficiently build powerful and high performance custom displays incorporating the process optimization features developed by the Abnormal Situation Management consortium.

1.7 Engineering station

It is used to configure all input & output and drawing and anything required to be monitored on Operator station monitor. Engineering notation or engineering form is a version of scientific notation in which the exponent of ten must be divisible by three (i.e., they are powers of a thousand, but written as, for example, 10^6 instead of 1000^2). As an alternative to writing powers of 10, SI prefixes can be used, which also usually provide steps of a factor of a thousand. Commodore scientific calculators offer the possibility of changing the exponent at will, therefore allowing the full choice of the unit in which the display may be read. This device, however, is limited to displaying only those numeric quantities for which there exists a commonly accepted alphabetic exponent notation. This device is also limited in the range of data that it can display. As an alternative to writing powers of 10, SI prefixes can be used, which also usually provide steps of a factor of a thousand. Commodore scientific calculators offer the possibility of changing the exponent at will, therefore allowing the full choice of the unit in which the display may be read. This device, however, is limited to displaying only those numeric quantities for which there exists a commonly accepted alphabetic exponent notation.

1.8 General Architecture of DCS

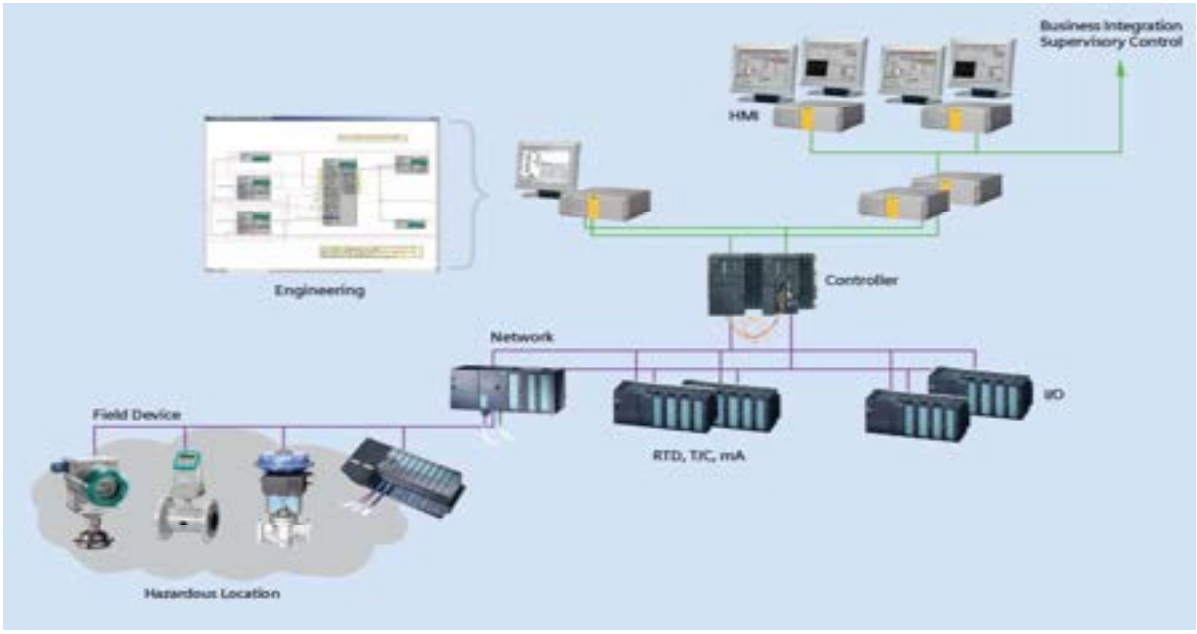

Figure 1.4 General DCS architecture

1.8 Basic elements of DCS

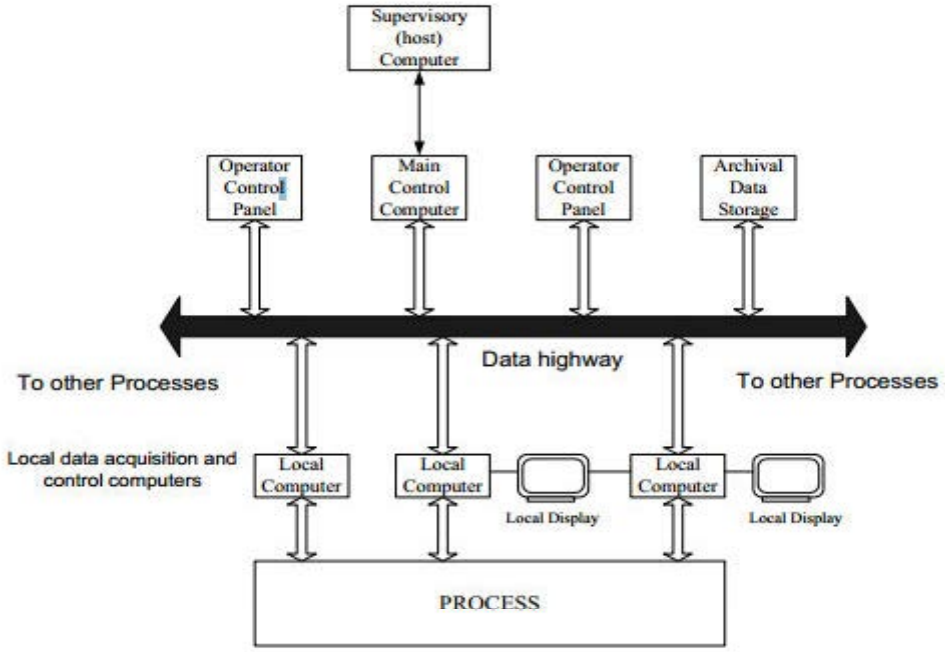

Figure 1.5 The elements of a commercial DCS network

- **Local Control Unit (LCU**):This is denoted as local computer in Figure 3. This unit can handle 8 to 16 individual PID loops, with 16 to 32 analog input lines, 8 to 16 analog output signals and some a limited number of digital inputs and outputs.
- **Data Acquisition Unit**: This unit may contain 2 to 16 times as many analog input/output channels as the LCU. Digital (discrete) and analog I/O can be handled. Typically, no control functions are available.
- **Batch Sequencing Unit:**Typically, this unit contains a number of external events, timing counters, arbitrary function generators, and internal logic.
- **Local Display:** This device usually provides analog display stations, analog trend recorder, and sometime video display for readout.
- **Bulk Memory Unit**:This unit is used to store and recall process data. Usually mass storage disks or magnetic tape are used.
- **General Purpose Computer**: This unit is programmed by a customer or third party to perform sophisticated functions such as optimization, advance control, expert system, etc.

- **Central Operator Display:** This unit typically will contain one or more consoles for operator communication with the system, and multiple video color graphics display units.
- **Data Highway:** A serial digital data transmission link connecting all other components in the system may consist of coaxial cable. Most commercial DCS allow for redundant data highway to reduce the risk of data loss.
- **Local area Network (LAN):** Many manufacturers supply a port device to allow connection to remote devices through a standard local area network

1.10 System Analysis

1.10.1 Existing System

The existing system of our project have only one reject conveyor.It collect reject material and It creates the environmental hazards.

1.10.2 Disadvantage

- It creates more environmental impacts.
- It need more manul power.
- It takes more time and money.

CHAPTER 2

LITERATURE REVIEW

2.1 Sorting of Objects Based on Color Type on A Conveyor Line Using PLC

S. V. Rautu, A. P. Shinde, N. R. Darda,A. V.Vaghule, C. B.Meshram, S.S.Sarawade (Department of Mechanical Engineering, M.E.S. College of Engineering, Pune, S.P. Pune University, India).

2.1.1 Introduction

Automation is the use of control systems for handling different processes and machineries to replace human efforts. Automated systems generally use complex algorithms which increase the cost of the design and the power consumed. But this not only reduces manual efforts, time consumed, but gives more time to work on factors like aesthetics. Using automation also prevents danger which might occur when humans are made to work in hazardous environments. Thus, use of automation is effective in manufacturing industry. Sorting based on colour, weight and type is done in many industries to ensure the quality of the object is consistent and up to the mark. Automated sorting also reduces the labour cost and the production time. The error cased due to human negligence are avoided by the use of automated system by colour based sorting using a colour sensor. Sorting of products in an industry is a tedious industrial process, which is generally carried out manually. Continuous manual sorting creates quality consistency issues. Segregation based on different characteristics like weight, colour, type require different equipment for weighing and then separating. We have proposed an efficient method which uses load cell, inductive sensor and TCS 230 colour sensor for identifying and segregating on the basis of weight, colour and type (metal or non-metal) of object and Siemens 300 Series PLC to control the overall process of sorting two types of objects. We have proposed an efficient method which uses load cell, inductive sensor A circular container, having three partitions is used to collect objects of three different colours. Two conveyor belts were used, each controlled by separate DC motors.

2.1.2 Proposed Method

In this project, we have proposed a Low Cost Automation System for sorting coloured objects on the basis of their colour, weight variation and type(metal or non-metal). The project mainly focuses on sorting 2different weighing non-metallic objects which are available in 3 different coloursusing load cell, TCS230 coloursensor, inductive sensor and DC geared motors interfaced with Programmable Logic Controller (PLC, which is operated using the DC motor. It comprises of a bridge on which the DC motor is mounted to which the flipper is attached. As soon as the PLC receives a signal from the load cell or the inductive sensor for a particular object, the flipper is initiated and if the object has undesired properties than the required ones, it slides the object into the rejection system; or the flipper slides it on the secondary conveyor line if it has the weighs as the weight set for secondary conveyor belt. If neither of the above conditions hold true and the object weighs as per the weight limit set for the primary line, the flipper leaves the object undisturbed and it continues on the primary conveyor line. The system consists of total 2colour sensors, an inductive sensor and a load cell, all used to detect the colour, type and weight respectively.

2.1.3. Drawbacks

- Increase the cost of the design.
- This not only reduces manual efforts.
- Time consumed, but gives more time to work on factors like aesthetics.

2.2 State-of-the-Art Reject Treatment Systems for Recycled Fiber Lines

Avinash P. Kaldate 1, Sachin A. Kulkarn, Assistant Professor, Sinhgad college of engineering, Vadgaon(B.K.), Associate Professor, Sinhgad college of engineering, Vadgaon (B.K.), Pune**.**

2.2.1 Introduction

Waste from paper mills has long been neglected and simply sent to landfills. This situation is changing rapidly due to legal requirements, and even more because of the huge economic benefits that can be accomplished by converting the rejects into valuable

sources of energy or new raw materials. These benefits include avoiding costs for transportation, handling, and disposal saving energy costs by generation of RDF (refuse-derived fuels): burning the reject fraction with high calorific value instead of purchasing fossil fuels, especially as energy and fuel prices are steadily rising income generated from selling various fractions of the reject compound government subsidies and funding By way of example, the following figures show price trends for various fuels and for electricity over the last decade. These trends show clearly that alternatives for energy generation and greater independence from market energy prices are the main drivers for "waste-to-energy" reject treatment. Rejects can be split into two major categories: coarse and fine rejects. While the coarse rejects mainly come from the pulping process, including de-trashing, the fine components originate from the cleaning and screening stages. Both categories – coarse and fine – can be divided into light and heavy rejects. A ballistic separator is applied very early on in the process, either directly after coarse metal separation or even before it. It is recommended particularly in reject systems for drum pulping lines, where the heavy particles enter along with the main reject stream, while these stones and bricks typically end up in the heavy fraction in conventional pulping lines.

2.2.2 Proposed Method

In many mills, both pulping methods are applied and thus, the mills need a reject treatment system that can handle rejects from both. In addition to the rag shredder, a coarse shredder is also recommended for the loose pulping rejects. This homogenizes the reject stream, reduces the size of very large particles and cuts the longish, rag-like components that can come from drum pulping – especially if there are too many wires entering the drum pulper. A first separation stage removes large metal pieces and the bulk of the wires from the rag. After passing through an optional ballistic separator for the pulping rejects, both streams are then compacted and dewatered together. often with additional waste and rejects delivered from external sources. The loose rejects from drum pulping or from wash drums in conventional pulping are often dewatered particle size for the subsequent sorting processes and for the boiler.As an additional step, a sieving unit is recommended. Only the larger particles (larger than approx. 15 to 20 mm) reach the optical sorting stage. nd are finally bunkered. In many cases, one mill location contains several lines. It makes sense to treat those rejects centrally in a single reject system .

2.2.3. Drawbacks

- It cannot be Achieved with certain recycled fractions.
- It consume more power.

2.3 Color/Metal sensing sorting system

Pankaj Agarwal ,Ratnesh Kumar tiwari, Samardeep Banyal, Santosh Kanigicherla, Shivang Chaudhary Department of Electronics and communication, SRM Institute of Management & Technology, SRM University, NCR Campus

2.3.1 Introduction

A robot can be defined as a programmable, self-controlled device consisting of electronic, electrical, or mechanical units. Robot is an integral part in automating the flexible manufacturing system that one greatly in demand these days. Robots are now more than a machine, as robots have become the solution of the future as cost labour wages and customers demand. Robot and automation is employed in order to replace human to perform those tasks that are routine, dangerous, complex and in hazardous area.[6] This article is based on the research project which is a fully automated material handling system to be use in industry. Even though the cost of acquiring robotic system is quite expensive but as today's rapid development and a very high demand in quality with International Standard Organization (ISO) standards, human are no longer capable of such demands [14]. Research and development of future robots is moving at a very rapid pace due to the constantly improving and upgrading of the quality standards of products. This paper aims at fully automated material handling system. This can be done by using sensors interfaced with Micro Controller Unit. It synchronizes the movement of robotic arm to pick the objects moving on a conveyor belt. It aims in classifying the coloured objects which are coming on the conveyor by picking and placing the objects in its respective pre-programmed place. Thereby eliminating the monotonous work done by human, achieving accuracy and speed in the work. This robot involves colour sensors that senses the object's colour and sends the signal to the microcontroller. This paper aims at fully automated material handling system. This can be done by using sensors interfaced with Micro Controller Unit.

2.3.2 Proposed Method

The pick and place robotic arm with conveyor belt is a system that detects the object on the conveyor belt, picks that object from source location and places at desired location based on colour identified or metal/nonmetal. For detection of object, firstly infrared sensors are used which detect presence of object as the transmitter to receiver path for infrared sensor is interrupted by placed object. Also the colour of the object is detected by the colour sensor. Its metallic nature is detected by the metal detector. Now As soon as robotic arm receives the signal from the controller, it picks with end effectors and places it on the respective destination depending on the respective colour of the object that is red, green or blue. If another object causes interrupt, it again does the same job. The system uses AT89S52 Micro Controller Unit as its controller for performing different operations by the robot. An Infrared sensor is an electronic device that measures infrared (IR) light radiating from objects in its field of view. IR sensors are often used in the construction of IR-based motion detectors apparent motion is detected when an infrared source with one temperature, such as a human, passes in front of an infrared source with another temperature, such as a wall. It is the same principle in all Infra-Red proximity sensors. The basic idea is to send infra red light through IR-LEDs, which is then reflected by any object in front of the sensor.

2.3.3 Drawbacks

- It has less quality.
- They have low efficiency.
- poor consistency.
- It can be operate only less flexibility.

2.4 Automatic waste segregator

International Journal of Innovative Technology and Exploring Engineering (IJITEE) ISSN: 2278-3075, Volume-8 Issue4S, February 2019.

2.4.1 Introduction

The rising population of India poses serious threats with regard to the availability of living space, utilization of natural resources and raw materials, education and employment. But another serious peril that follows is the escalating amount of waste

generated each minute by an individual. Every city is grappling with the menace of ever increasing waste. An astounding 0.1 million tonnes of waste is generated each day in our country. Sadly, only 5% of this colossal amount of waste is recycled. In India, the collection, transportation and disposal of MSW are unscientific and chaotic. Uncontrolled dumping of waste on outskirts of towns and cities has created overflowing landfills which are not only impossible to reclaim because of the haphazard manner of dumping but also has serious environmental implications. When viewed on a larger scale, the poor recovery rate has impeded the growth of the country as well as the economy of the nation. One possible solution for this problem could be segregating the waste at the disposal level itself. We have thus come up with an Automatic waste segregator that categorizes the waste as wet, dry or metal. An 8051 microcontroller forms the heart of the system. Inductive proximity sensor is used to detect if the waste is a metal. Wet and dry waste can be distinguished based on their weight. A high speed blower system is used to blow dry waste off the belt while most of the wet waste remains. It then falls off as the belt rotates and is collected later. This cost effective system is particularly suitable for installation in apartments and colonies.

2.4.2 Proposed Method

The open close mechanism acts as a regulator to control the waste that falls on the belt. A 12V DC geared motor receives inputs from microcontroller to monitor the clockwise and anti clockwise motion of the motor. This mechanism is initiated only if the IR sensor detects a waste in its vicinity. An inductive proximity sensor based on the eddy current principle suitable for detecting buried conductive targets has been used. Three 12V inductive proximity sensors are used to detect if the incoming waste is metallic or not. This is fed as input to the microcontroller. As and when the inductive proximity sensors detect a metallic waste, a slider movement is initiated which sweeps the waste away after it falls on the belt. Permanent magnets within the metallic bin aid in sorting magnetic metals from non-magnetic ones. Dry and wet separation is based on their weight. Due to its high density and weight, wet waste refuses to be blown off even in the presence of a high speed blower. This technique is made use of to distinguish wet and dry waste. A relay will control the on and off of a high speed AC blower. As blower blows, the belt halts and dry waste is thrown out into the dry bin via a collecting chamber. Wet waste stays on the belt. It then falls off due to gravity at the end of the belt as it rolls. Permanent magnets within the metallic bin aid in

sorting magnetic metals from non-magnetic ones. Dry and wet separation is based on their weight. Due to its high density and weight, wet waste refuses Dry and wet separation is based on their weight. Due to its high density and weight, wet waste refuses to be blown off even in the presence of a high speed blower. It then falls off as the belt rotates and is collected later. This cost effective system is particularly suitable for installation in apartments and colonies.

2.4.3. Drawbacks

- Segregation of waste consumes more time.
- Segregation is very complex.

2.5 Automatic Broke Feeding System for the Finishing House Pulper in Paper Machine

V. Ravichandran 1, Aravinth S.A.S 2, Dinesh M 2, Midhun Johny 2, Mohanasundaram K.S Asst. Prof., Department of EEE, Nandha Engineering College, Erode, India 2 UG scholar, Department of EEE, Nandha Engineering College, Erode, India.

2.5.1 Introduction

Paper mill is a factory that makes paper from vegetable fibers, wood pulp, old rags and other materials. Large scale paper mills produce nearly 4,00,000 tons of paper annually. The non ending demand for papers makes it necessary to minimize the losses and improve the efficiency of paper machine. Hence all paper mills recycle the wastes produced in each stage of paper production. Once such recycling process is broke feeding in finishing house pulper. About 10% of paper wastes called brokes are produced daily due to improper paper size ,creases, etc. These wastes are converted back to pulp and send to pulp tower from where it will return to the initial stage to get converted back to paper. This will improve the production of the paper mill. This broke feeding process is carried out manually, by collecting all the brokes and then making it to pulp by mixing it using agitator. The pulp is then pumped to the pulp tower. By automating the broke feeding the productivity of the paper mill can be increased. The collection of brokes cannot be automated. Hence the brokes are collected manually. The rest of the process can be automated using PLC. The broke feeding section has hydraulic lift, broke cage, broke remover, conveyor belt and an agitator. The sensors used are load cell and proximity sensor. Paper mill is a factory that makes paper from vegetable fibers, wood pulp, old rags and other materials. Large scale paper mills

produce nearly 4,00,000 tons of paper annually. The non ending demand for papers makes it necessary to minimize the losses and improve the efficiency of paper machine. Hence all paper mills recycle the wastes produced in each stage of paper production. Once such recycling process is broke feeding in finishing house pulper. About 10% of paper wastes called brokes are produced daily due to improper paper size ,creases, etc.

2.5.2 Proposed Method

In a paper mill, there are several paper cutting machines and pulp mixer. They produced 1500 MT of paper per day. About 10% of this production will be considered as waste, due to incorrect GSM (paper size), paper cutting, etc. This waste papers are called as brokes. These kinds of wastes are recycled by the industry. Workers collects the whole broke, broke is nothing but the paper waste. This broke is brought to the finishing house pulper section. The brokes are then lifted to put the broke into the pulper. Then tap is opened till the water reaches the prescribed level. Next the mixeris started. The whole process is done manually now. At least 3 workers are needed for this continuous process and it s also time consuming. This is the existing system for recycling the brokes in a paper mill. Fig 3 shows the existing broke feeding method in a paper mill. The brokes are collected from various stages of the paper machine. As the opening of the mixer is on the top the brokes are lifted using a lift. Then the brokes are transferred to the mixer manually. Also small paper wastes from various stages are bought to the mixer by pulp vessel. After the brokes are filled in the mixer, water is filled. Only 70% of the mixer is filled with water to avoid spilling. Then the agitator is turned ON. After thirty minutes the brokes will become pulp and will be transferred to pulp tower using a pump. Also small paper wastes from various stages are bought to the mixer by pulp vessel. After the brokes are filled in the mixer, water is filled. Only 70% of the mixer is filled with water to avoid spilling. Then the agitator is turned ON. After thirty minutes the brokes will become pulp and will be transferred to pulp tower using a pump.

2.5.3 Drawbacks

- It also reduces the time taken for broke recycling.
- It reduces 2 men’s workload.

2.6 Potential benefits of recovered paper sorting by advanced technology

"Gheorghe Asachi" Technical University of Iasi, Faculty of Chemical Engineering and Environmental Protection, 71, Dimitrie Mangeron Blvd., 700050 Iasi, Romania.

2.6.1 Introduction

Quality is the major prerequisite for extending the use of recovered paper (RP) as a raw material for paper and board manufacturing. Several studies related to furnish quality focus on recovered paper from household collection, which is the main source with potential for further increasing the recycling rates. The first part of the paper analyses the role of household collection for future development of paper recycling and trends of RP quality in Europe. Many studies have demonstrated that an extended household collection is always detrimental to RP quality. Without the adequate actions of all actors from the recycling chain, quality decrease could jeopardize the sustainability of paper recycling. In this context, many researches on the improvement of recovered paper quality are being carried out in Europe. A representative example for this research field is FP7 project – SORT IT (Recovered Paper SORTing with Innovative Technologies), whose objectives of RP quality improvement and expected benefits are analysed briefly in the second part of this paper. In the survey on the general parameters influencing the future competitiveness of paper recycling in Europe, the partners of COST Action E48 were asked to rank the importance of different means in improving paper collection efficiency in their country. The general results, expressed as average levels of 19 countries, show15 that advanced sorting of recovered paper is, after the collection system, the second most important area for extending the limits of paper recycling in European countries.

2.6.2 Proposed Method

Due to its low price, recovered paper is a very attractive fibre raw material for paper and board manufacturing. Generally, mixed grades (1.01, 1.02) are sorted to obtain more homogenous and higher quality grades (deinking grade 1.11 and packaging grade 1.04), traded at higher prices. Therefore, until recently, a low manufacturing cost was the most important driving force for substituting virgin pulp with the recycled pulp obtained from recovered paper processing. The benefits of substituting recycled for virgin fibre are

generally greater for higher grades (especially for paper made from chemical pulp) than for lower grades, such as newsprint, liner and fluting for corrugated boxes, and hygienic paper. Actually, the use of recycled fibre pulp in producing high grades is limited to about 10%, the main causes of this limitation being the high quality demand for fibre pulp quality and the quality decrease of the recovered paper available for recycling. tending the use of recovered paper as a raw material, and the major threat – if sufficient quality cannot be assured. A considerable amount of research related to furnish quality is carried out in Europe, most of it focusing on the recovered paper from household collection. Generally, mixed grades (1.01, 1.02) are sorted to obtain more homogenous and higher quality grades (deinking grade 1.11 and packaging grade 1.04), traded at higher prices. Unfortunately, today's sorting technologies cannot overcome the low and variable quality of recovered paper input. As documented below, the trend of quality decrease for mixed grades is translated into both deinking and packaging grades obtained by mixed grades sorting. Several studies of the SORT IT project30 evidenced the following composition ranges for grade 1.04: non-paper components from 1.5 to 3%; non-recyclable paper and board from 3 to 6%; graphic papers from 5 to 30%.

2.6.3 Drawbacks

- Energy consumption is less.
- lower contamination of recovered paper grades.

2.7 Development of Automatic Smart Waste Sorter Machine

Mahmudul Hasan Russel1* , Mehdi Hasan Chowdhury1 , Md. Shekh Naim Uddin1 ,Ashif Newaz1 , Md. Mehdi Masud Talukder2 Department of Electrical and Electronics Engineering1 , Department of Mechanical Engineering2 Chittagong University of Engineering and Technology (CUET) Chittagong-4349, Bangladesh.

2.7.1 Introduction

Modern world meets lots of challenges that includes Smart waste management system. It is become matter of big concern if proper disposal system is not managed. Managing waste effectively and recycling efficiently, a nation can ahead one step forward. In this work, an automatic sorter machine is developed which can sort out the wastes in various categories to make waste management easier and efficient. It can be possible to sort

out metal, paper, plastics and glass by developing an electromechanical system using microcontroller and operational amplifier. For sorting metal and glass conventional sensors are used and for sorting paper and plastics a sensor using LASER and LDR is developed. A weight sensor and counter is used to find out the amount of sorted materials. By using the proper recycling system, the curse of waste will turn into blessings for the civilization. The sorting procedure will make recycling more efficient. By means of this waste sorter, the conventional waste management system will be transformed into SMART system. This SMART system will help to make our environment more suitable for living, reducing global warming and making the world healthier. From the beginning of the human civilization, people used various methods of waste disposal to get rid of unwanted material. Sometimes it was buried in the land, thrown in the sea, fed to the animal or burnt. Getting rid of unwanted material is always a major concern for the modern society.By means of this waste sorter, the conventional waste management system will be transformed into SMART system. This SMART system will help to make our environment more suitable for living, Trash has played a tremendous role in history. The Bubonic Plague, cholera and typhoid fever, to mention a few, were diseases that altered the populations of Europe and influenced monarchies.

2.7.2 Proposed Method

The system activates when the IR detects some sorts of material is being put on the system tray. Then at first the weight sensor activates and find out the weight of the trash, then the metal sensor and glass sensor starts their actions. If metal sensor detects the material as metal, then a servo motor will put that trash in the bin 3 (which is dedicated for metals). If the glass sensor detects glass then it will perform same action and put the trash in bin 4. If both sensors fail to detect then the LASER and LDR activates. If the LASER passes through the trash then it is decided as a transparent and moves to bin 2. If the LASER fails to pass then the material is decided as Paper and move to bin. The sorting system consists of Light Dependent Resister (LDR), LASER, Infrared (IR) transmitter and receiver, Metal Sensor (Capacitive proximity sensor E2K-C) glass sensor (Omron E3SCR67C), Weight Sensor (MLC900 micro weight sensor) and a Liquid Crystal Display (Alpha-numeric 16*4 LCD). The whole program is run by a microcontroller (PIC 16f877A). The Servo motor is controlled by sending a pulse of variable width by the microcontroller. The control wire is

used to send this pulse. The parameters for this pulse are that it has a minimum pulse, a maximum pulse, and a repetition rate. Given the rotation constraints of the servo, neutral is defined to be the position where the servo has exactly the same amount of potential rotation in the clockwise direction as it does in the counter clockwise direction. It is important to note that different servos will have different constraints on their rotation but they all have a neutral position, and that position is always around 1.5 milliseconds (ms). If the LASER passes through the trash then it is decided as a transparent and moves to bin 2. If the LASER fails to pass then the material is decided as Paper and move to bin. The sorting system consists of Light Dependent Resister (LDR), LASER, Infrared (IR) transmitter and receiver, Metal Sensor (Capacitive proximity sensor E2K-C) glass sensor (Omron E3SCR67C), Weight Sensor (MLC900 micro weight sensor) and a Liquid Crystal Display (Alpha-numeric 16*4 LCD).

2.7.3 Drawbacks

- Reduction of Cost is high.
- It doesn't have Primary Recycling and Reusing Unit.

2.8 Fiber Recovery from Waste Paper: A Breakthrough in Re-Pulping Technology

Jerry Aue, Energy Center of Wisconsin Keith Picard, Fiber Recycling Technologies, Inc. Kevin Grabner, Energy Center of Wisconsin Alan Button, Buttonwood Consulting, LLC

2.8.1 Introduction

Paper mills and converters produce large quantities of waste paper. Paper trim from the process, roll ends, off-quality product and overruns are all sources of waste. Where feasible, process scraps are re-pulped and blended back into the feedstock. Converting paper to its final product sometimes produces wastes that are difficult if not impossible to re-pulp with conventional technology. For example, many paper products are laminated with plastic. Many mills either process laminated waste paper into pellets for boiler fuel or pay to have the wastes land filled. This paper describes a new technology that cost-effectively recovers quality fiber from papers currently being sent to landfill. Fiber Recycling Technologies, Inc. (FRT) has developed a low-energy, mechanical re-pulping method that gently separates fibers while leaving contaminants largely whole, so that fiber can be readily screened from

contaminants. Trials were run on a range of recovered papers and landfill waste, including poly-laminated paper trimmings, multilaminated food packaging, and unsorted municipal solid waste. Success from the trials encouraged FRT to start a commercial re-pulping operation using their own technology. This expanding new business re-pulps high-grade landfill waste papers, creating 18 new jobs. Recovered papers can use considerably less energy in pulping than wood-based pulp, so making secondary fibers competitive with virgin ones can save significant energy. A 20- ton per day FRT pulper now operating commercially annually saves about 7,000 tons of waste fiber from being land filled, and requires 11 to 30 kWh per ton for pulping. By comparison, refiner-mechanical pulping of virgin wood requires about 1,972 kWh per ton (Martin, N., et al 2000). Other mechanical and kraft pulping processes have similar or greater energy intensities.

2.8.2 Proposed Method

The U.S. pulp and paper industry is made up of three primary types of producers: 1) pulp mills, which manufacture pulp from solid wood or other materials, primarily wastepaper; 2) paper mills, which manufacture paper from wood pulp and other fiber pulp; and 3) paperboard mills, which manufacture paperboard products from wood pulp and other fiber pulp. In 1994, virgin wood pulps accounted for 68% of paper production by weight, with used paper covering the remaining 32%, when 82.46 million tons of paper were produced in the U.S. (Martin, N., et al 2000). More than 5.3 million tons of paper and over one million tons of paperboard are produced annually in Wisconsin (Wisconsin Paper Council 2003). Since recovered papers can use considerably less energy in pulping than wood-based pulp, making secondary fibers competitive with virgin ones can save significant energy in the mill (Martin, N., et al 2000). As the United States paper industry approaches its 50% recovered paper target, getting that last couple of percent has gotten difficult. While there is potentially significant additional recovered paper tonnage, the paper industry faces a difficult challenge to collect and process much of this material in an economically attractive fashion. Among the obstacles to increasing the recovered paper percentage are papers with difficult to remove and separate contaminants and quantities of particular recovered paper grades that are too small to justify separating and/or marketing. Difficult to process recovered papers include those with coatings and laminations (such as plastic or foil) that

are easily fragmented and difficult to remove in conventional cleaning and screening operations.

2.8.3 Drawbacks

- Paper rapidly with low specific energy usage.
- Pulp properties were comparable to a highly efficient.

2.9 A critical review on waste paper sorting techniques

M. O. Rahman A. Hussain H. Basri . Received: 20 September 2012 / Revised: 10 January 2013 / Accepted: 23 February 2013 / Published online: 4 April 2013 Islamic Azad University (IAU) 2013

2.9.1 Introduction

Efficient waste paper recycling has a significant role in the sustainable environment. Recyclable waste paper as a fundamental ingredient of municipal solid wastes (MSWs) is indeed an ‘‘urban ore’’. Waste papers are considered as the solid recovered fuel which is recovered from MSW. Recyclable waste papers are segregated into various grades to produce high-quality products. Moreover, sorted paper streams save energy, chemicals, and water, as well as reduce sludge and rejects. Information technology is widely integrated with the waste management industry into its operations such as recycling, reuse, segregating based on categories and so on. This review article focuses on the life cycle of waste paper and existing waste paper sorting techniques. In the paper industry, many types of sensors are used in different mechanical and optical waste paper sorting systems. Such sensors include lignin, gloss, stiffness, mid-infrared, infrared, and color sensors. In this review, also described the effectiveness of different waste paper sorting systems, and finally, recommended appropriate waste paper. Paper comprises a network of plant fibers laid down as a flat sheet that is made from a suspension of plant tissues in water, known as pulp. Etymologically, ‘‘paper’’ is derived from ‘‘papyrus,’’ the Ancient Greek word for Cyperus papyrus. The plant fiber of waste paper is reusable for six to seven times (Villanueva and Wenzel 2007). Hence, the demand for recyclable waste paper is rapidly increasing in the global market of pulp production. Although the total production capacity of all Malaysian paper mills reaches 1,300,000 tons/year, consumption remains higher than production

capacity (Asia Pro Eco Program 2006). The Malaysian pulp and paper industry is heavily dependent on imported fiber, particularly virgin pulp. Hence, the industry has to find a new source of fiber to strengthen and retain the quality of secondary fibers given the growing use of recycled paper in Malaysia.

2.9.2 Proposed Method

In recycled pulp production, pulp from recyclable waste paper is manufactured by grinding collected waste paper in water. After deinking and the removal of impurities, the pulp is ready for paper production. Waste paper fibers are worn down or downgraded when they undergo recycling. Hence, fibers may be recycled for only six to seven times (Villanueva and Wenzel 2007). Moreover, the addition of virgin pulp is necessary to retain the total stock of paper during recycled paper production from collected waste paper. Waste paper pulping generally requires less energy per ton of pulp than pulping processes that use virgin fibers. In addition, this process saves virgin fiber inputs in paper production. Compared with the chemical pulping of wood from virgin sources, waste paper pulping generates no wood wastes nor dissolved chemicals for energy generation. Consequently, when waste paper utilization is increased, the availability of biomass energy is reduced, and the dependence on purchased energy, such as fossil fuels, increases. The vendor–customer entity is considered the initial source of waste paper. The end user of the finished paper/paper products stores the paper in a bin or in a collection area for recycling after use. The vendor–customer represents the bin or collection area. The dealer collects the waste paper from vendor–customers. The collected waste paper contains both relevant and non-relevant waste. The dealer supplies the collected waste paper to the godown owner. At this stage, the recyclable and non-recyclable waste papers are segregated. Thereafter, the recyclable waste papers are sorted into categories according to the demand of the paper manufacturer or of the paper industry for appropriate pricing. The supplier collects the relevant waste paper for recycling from the godown owner and supplies it to the paper industry or manufacturers.

2.9.3 Drawbacks

- Paper consumption is less.
- It produces a low-quality product.

Summary of Literature Review

The summary of literature review is given in the table 2.1 contains the title of the paper,techniques used and its drawback.

Table 2.1 Summary of literature

S.NO	TITLE	OBJECTIVE	DRAWBACK
1.	potential benefits of recovered paper sorting by advanced technology	It is used to recovered paper (RP) as a raw material for paper and board manufacturing	▪ Energy consumption is less. ▪ lower contamination of recovered paper grades
2.	colour/metal sensing sorting system	To increase the manufacturing capacity for industries and eliminate the manual based tasks and operations.	▪ Less quality & efficiency. ▪ poor consistency & flexibility**.**
3.	Sorting of Objects Based on Color, Weight and Type on A Conveyor Line Using PLC	To sort objects depending upon the color. To design easy and simplified operational system.	▪ Paper consumption is less. ▪ It produces a low-quality product
4.	A critical review on waste paper sorting techniques	Recyclable waste papers are segregated into various grades to produce high-quality paper.	▪ Paper consumption is less.

			▪ It produces a low-quality product
5.	Automatic waste segregator	It deals with the minimization of blue-collar method utilization for exclusion of waste into an automated panache.	▪ Segregation of the waste consumes time
6.	Automatic broke feeding system for the finishing house pulper in paper machine	The ultimate aim of this project is to automate and control the above process by designing a control system using Programmable Logic Controller.	▪ It also reduces the time taken for broke recycling. ▪ It reduces 2 men's workload
7.	Development of Automatic Smart Waste Sorter Machine.	In this work, an automatic sorter machine is developed which can sort out the wastes in various categories to make waste management easier and efficient.	▪ Reduction of Cost is high. ▪ It doesn't have Primary Recycling and Reusing Unit.
8.	State of the art reject treatment systems for recycled fibre lines	mechanical dewatering and compacting, cutting and shredding to set the desired particle size, sorting of unwanted materials and impurities.	▪ It cannot be Achieved with certain recycled fractions.

9.	Fiber recovery from waste paper a breakthrough in re-pulping technology	Converting paper to its final product sometimes produces wastes that are difficult if not impossible to re-pulp with conventional technology.	▪ Paper rapidly with low specific energy usage. ▪ Pulp properties were comparable to a highly efficient.

CHAPTER 3

PROPOSED SYSTEM

3.1 Proposed system

In this proposed method ,the waste paper is obtained from the waste products. It has two reject conveyors. The two reject conveyors are connected in serious connection. The two reject conveyors are operated in based on time.The reject conveyor I consist of metal separator which is used to separate the metal from the reject wastage. Then the reject waste material are passed through the bailing machine with the help of reject conveyor II. The reject conveyor II carries the waste materials such as polythene and etc. The metal separator attracks the metals and iron components. The obatained metals are passes to the scrap yard .In this scrap yard this metals are melted and its used to reproduce the another metal product. The polythene papers are send to the kiln and its used in cement plant for raise the temperature. The reject conveyor II having the waste papers which is passes to the bailing machine. After receiving the bailing machine the papers are compressed and its bundled with the help of iron strip. Then the reject conveyor I and reject conveyor II works at simultaneously before filling the bailing machine. When the bailing machine was filled the reject conveyor II works based on the timer, we set the run time and stop time.

3.2 Block diagram

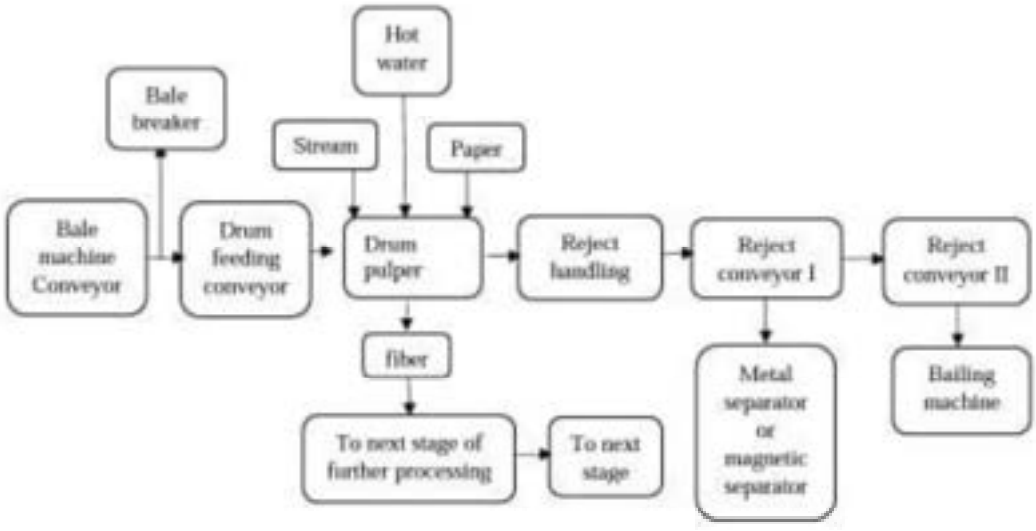

Figure 3.1 Block diagram of proposed system

3.2.1 Bale machine conveyor

A baler, most often called a hay baler is a piece of farm machinery used to compress a cut and raked crop (such as hay, cotton, flax straw, salt marsh hay, or silage) into compact bales that are easy to handle, transport, and store. Often, bales are configured to dry and preserve some intrinsic (e.g. the nutritional) value of the plants bundled. Different types of balers are commonly used, each producing a different type of bale – rectangular or cylindrical, of various sizes, bound with twine, strapping, netting, or wire.Industrial balers are also used in material recycling facilities, primarily for baling metal, plastic, or paper for transport.A type of baler that produces small rectangular (often called "square") bales was once the most prevalent form of baler, but is less common today. It is primarily used on small acreages where large equipment is impractical, and also for the production of hay for small operations, particularly horse owners who may not have access to the specialized feeding machinery used for larger bales. Each bale is about 15 by 18 by 40 inches (38 cm × 46 cm × 102 cm). The bales are usually wrapped with two, but sometimes three, or more strands of knotted twine. The bales are light enough for one person to handle, about 45 to 60 pounds (20 to 27 kg), depending upon the crop and pressure applied (can be 100 lbs for a 16"x18" 2-string bale). Many balers have adjustable bale chamber pressure and bale length, so shorter, less-dense bales can be produced for ease of handling.

3.2.2 Bale breaker

In order to transport recyclable materials economically over long distances after the first treatment stage, they are pressed into bales of different sizes. These bales must be broken up after transport in order to feed the recyclable materials to the following processing steps. Work safety has the highest priority today. Removing wires from wrapped bales is a dangerous operation when carried out manually. For this reason, our customers have entrusted us with the development of the bale breaker. These machines can process the following types of bales without any problems,

- Mixed Plastic Bales
- Paper Bales
- Bottle Bales

3.2.3 Feeding Conveyor

Feeding Conveyor as a solution in the material handling equipment. Our range of conveyor are designed and manufactured to give high durability and efficient performance. Our range of conveyors is rich in reliability and thus helps in the reduction of the maintenance and cost of the equipment. Made from Mild steel plates, our Material Feeding Conveyors are useful in the functioning of the oil mill plants. These are used in the feeding of seeds and cakes. Our conveyors are available in various sizes, capacities and specifications. These sizes vary from 6 inches to 15 inches. Our company also offers customization facility to our clients as per their needs and requirements.

In our conveyor, the screw is enclosed in a flexible or rigid plastic tube, or a rigid steel tube, which is driven by an electric motor and is normally, located at the discharge end of the conveyor. Also, a removable clean-out cap is placed to cover the intake end of the conveyor tube, thus enabling the conveyor for rapid emptying and flushing tube. It also helps in the disassembling and washing down of the components. Thus, making our range of conveyors more appropriate for the related industries.

3.2.4 Drum pulper

Pulpers play an important role in recovered paper stock preparation. The pulpers mechanically break down the recovered paper under simultaneous addition of water. The pulping system significantly affects both the cost-effective designing of the entire stock preparation line and also the finished stock quality. All pulping systems slush down the paper completely, without damaging fibers and without breaking down nonpaper components. Minimum investment and operating costs and also minimum energy consumption are further important requirements. The function of the pulper is to gently slush the recycled paper raw material into a pumpable pulp, which is suitable for processing in stock preparation while facilitating the efficient removal of contaminants from the pulp. The design of the pulping and detrashing equipment should satisfy a number of process requirements presented as follows:

- Slush down the recycled paper to individual fibers without causing any fiber damage and reducing fragmentation of contaminants enabling efficient removal in the downstream cleaning and screening processes

- An efficient detrashing system for removing contaminants in the first stage of the stock preparation process
- Undertake ink detachment
- Effective blending of chemicals

To meet these process requirements, several pulping and detrashing systems have been developed and operated successfully.Vat-type pulpers often with batch operation are being used in many deinking plants. Recovered paper and water are charged to the vat, repulped, and afterwards drained from the vat. A batch process consumes more energy. Power demand peaks when the pulper is charged with paper. A batch pulper has a higher downtime because it is offline when being unloaded. Installing continuous drum or dry pulpers will reduce energy consumption. This may also reduce water use and associated water heating requirements.

3.3 Deinking Process

Deinking chemicals are generally added to the pulper (Lassus 2000). During pulping the recovered paper is slushed into a pulp at high consistency. The combination of chemical and mechanical action is favourable. Additionally, by dosing early in the process to the pulper the reaction time is increased as well as the more effective dosage of some chemicals as the result of a high consistency. Figure shows a schematic layout of a typical deinking process for the production of pulp for graphical grade paper. Often all deinking chemicals are added to the pulper, but sometimes some or all of the deinking aid can also be added to the flotation cell.Schematic layout of a deinking process for the production of deinked pulp for graphical grades showing possible addition places for deinking and bleaching chemicals. A variety of deinking aids exist. In traditional alkaline deinking these aids are often composed of fatty acids and/or non-ionic surfactants. Sodium hydroxide (NaOH) is also added for reasons such as ink detachment and ink dispersion. It is commonly believed that ink detachment is improved using sodium hydroxide both because of fibre swelling effects as well as chemical hydrolysis of some bonds between the substrate and some ink species. The pH at the exit of the pulper is often between 8.5-10.5 when deinking a newspaper/magazine furnish.

3.3.1 Neutral and low alkali deinking

A new trend for certain processes and mills in the deinking of newspaper and magazine based raw materials is to move away from traditional alkaline deinking and towards lower pH levels which are commonly referred to as "true neutral" deinking (pH about 6.8-7.2) and "reduced or low alkali" deinking (pH about 7.2-8.8). Often these desires are driven by chemical cost savings and/or environmental factors. In true neutral deinking only surfactant, usually a blend of different synthetic surfactants, is added to the pulper.

3.3.2 Surfactants

Surfactants are surface active agents. This chemically unique species have a dual character. This character consists of hydrophilic and hydrophobic portions of the chemical structure. In an aqueous environment, the hydrophilic portion is water loving and relatively polar while the hydrophobic part of the surfactant is water hating and relatively non-polar (Figure 2). Surfactants can be non-ionic, anionic, or cationic. For the anionic and cationic species the hydrophobic part normally includes a hydrocarbon chain (-CH2-CH2-) and the hydrophilic part includes a variety of chemical functionalities. These can include entities such as an amine group (-NH3), a carboxyl (-COOH), sulphonate (-SO3), or sulphate (-SO4) group among others. Non-ionic synthetic surfactants generally contain blocks or units of various alkoxylates, most commonly derived from either ethylene or propylene oxides.

3.3.3 Fatty acids

Fatty acids have been used to produce fatty acid salts (soaps) for centuries. These soaps have been used to remove dirt from different surfaces. Saturated fatty acids, such as stearic acid (18 carbons) or palmitic acid (16 carbons) are solid at room temperature while unsaturated fatty acids, like linoleic acid (18 carbons with two double bonds at the 9 and 12 positions) can be liquid . Fatty acid products are normally mixtures of several fatty acids with different structure.

CHAPTER 4

SYSTEM SPECIFICATION

4.1 Hardware Specification

- Motor(3phase)
- Conveyors
- Magenetic Seperator
- Bailing Machine
- Selector Switch

4.1.1 Motor(3 Phase)

A 3 phase motor is a motor which uses a 3 phase AC supply to work 3 phases means three circuit are used in which current lag from each other by 120 degree.

4.1.1.1 Stator

Stator of three phase induction motor is made up of numbers of slots to construct a 3 phase winding circuit which is connected to 3 phase AC source. The three phase winding are arranged in such a manner in the slots that they produce a rotating magnetic field after 3Ph. AC supply is given to them.

4.1.1.2Rotor

Rotor of three phase induction motor consists of cylindrical laminated core with parallel slots that can carry conductors. Conductors are heavy copper or aluminum bars which fits in each slots & they are short circuited by the end rings. The slots are not exactly made parallel to the axis of the shaft but are slotted a little skewed because this arrangement reduces magnetic humming noise & can avoid stalling of motor.

4.1.1.3 Working of Three Phase Induction Motor

The stator of the motor consists of overlapping winding offset by an electrical angle of 120°. When the primary winding or the stator is connected to a 3 phase AC source, it establishes a rotating magnetic field which rotates at the synchronous speed. Secret behind

the rotation, according to Faraday's Law an emf induced in any circuit is due to the rate of change of magnetic flux linkage through the circuit.

As the rotor winding in an induction motor are either closed through an external resistance or directly shorted by end ring, and cut the stator rotating magnetic field, an emf is induced in the rotor copper bar and due to this emf a current flows through the rotor conductor. Here the relative speed between the rotating flux and static rotor conductor is the cause of current generation; hence as per Len's Law theYIOP rotor will rotate in the same direction to reduce the cause i.e. the relative velocity.

Thus from the working principle of three phase induction motor it may observed that the rotor speed should not reach the synchronous speed produced by the stator. If the speeds equals, there would be no such relative speed, so no emf induced in the rotor, and no current would be flowing, and therefore no torque would be generated. Consequently the rotor can not reach the synchronous speed. The difference between the stator (synchronous speed) and rotor speeds is called the slip. The rotation of the magnetic field in an induction motor has the advantage that no electrical connections need to be made to the rotor. Thus the three phase induction motor is,

- Self-starting.
- Less armature Reaction and brush sparking because of the absence of commutators and brushes that may cause sparks.
- Robust in construction.
- Economical.
- Easier to maintain.

Figure 4.1 3 phase motor

If the speeds equals, there would be no such relative speed, so no emf induced in the rotor, and no current would be flowing, and therefore no torque would be generated. Consequently the rotor can not reach the synchronous speed If the speeds equals, there would be no such relative speed, so no emf induced in the rotor, and no current would be flowing. The difference between the stator (synchronous speed) and rotor speeds is called the slip. The rotation of the magnetic field in an induction motor has the advantage that no electrical connections need to be made to the rotor.

Table 4.1 Specification of motor

Parameter	Specification
Power	7.5 HP
Connetion	220V Double star
Coil	1-7
Line Voltage	208-230/460
Current	3.2-3/1.5
Magnetic Core Length	2"1/2

4.1.2 Conveyor

A conveyor belt is the carrying medium of a belt conveyor system (often shortened to belt conveyor). A belt conveyor system is one of many types of conveyor systems. A belt conveyor system consists of two or more pulleys (sometimes referred to as drums), with an endless loop of carrying medium the conveyor belt that rotates about them. One or both of the pulleys are powered, moving the belt and the material on the belt forward. The powered pulley is called the drive pulley while the unpowered pulley is called the idler pulley. There are two main industrial classes of belt conveyors; Those in general material handling such as those moving boxes along inside a factory and bulk material handling such as those used to transport large volumes of resources and agricultural materials, such as grain, salt, coal, ore, sand, overburden and more. Belt conveyors can be used to transport product in a straight line or through changes in elevation or direction. For conveying Bulk Materials like Grains, Ore, Coal, Sand etc., over gentle slopes or gentle curvatures, a

troughed belt conveyor is used. The trough of the belt ensures that the flowable material is contained within the edges of the belt. However, in this case the idler frame completely surrounds the conveyor belt helping it to retain the pipe section, while pushing it forward. In the case of travel paths requiring high angles and snake-like curvatures, a Sandwich Belt is used.

The trough is achieved by keeping the idler rollers in an angle to the horizontal at the sides of the idler frame. A Pipe Conveyor is used for material travel paths that require sharper bends and inclines up to 35 degrees. A pipe conveyor features the edges of the belt being rolled together to form a circular section like a pipe. Like a Troughed Belt Conveyor, a Pipe Conveyor also uses idler rollers. However, in this case the idler frame completely surrounds the conveyor belt helping d. In the case of travel paths requiring high angles and snake-like curvatures, a Sandwich Belt is used.

Figure 4.2 Conveyor

The sandwich belt design enables materials carried to travel along a path of high inclines up to 90 degree angles, enabling a vertical path as opposed to a horizontal one. This transport option is also powered by idlers.

Table 4.2 Specification of Conveyor

Parameter	**Specification**
Horizontal Length	148.5m
Width	650mm
Rated Capacity	100t/h
No of plies	3
Total thickness of belt	14.1mm
Belt speed	1.25 m/s

4.1.3 Magnetic Seperator

A magnetic separator is a device that uses a magnet to remove impurities and other magnetic materials from metal. Magnetic separators can be used before, during and after the production of a material and can be adjusted to attract different types of magnetic materials at different intensity levels.Although its use is almost always industrial in nature, a magnetic separator is used for a wide variety of applications. Magnetic separators can be ferromagnetic or paramagnetic and can vary in size from a table version to a large, heavy drum used in recycling and other manufacturing applications.

A magnetic separator consists of a powerful magnet that is placed or suspended from a ceiling or device. Materials can be passed over a table top magnetic separator, while suspended magnetic separators often hang over a material to remove its impurities. Magnetic separators can also be cylinders through which objects pass. The material that purifies a magnetic separator can be in the form of parts, a finished product or even a liquid metal. With this, a magnetic separator is characterized by,

- To be an excellent machine to separate magnetic materials from concentrates.
- Removes natural magnetic minerals such as magnetite, as well as steel filings from metal processing material and iron particles.
- Remove magnetic like gold concentrates, because it allows gold to recover much more easily.

Figure 4.3 Magnetic separator

Magnetic cell separation is on the rise. It is currently being used in clinical therapies, more specifically in cancers and hereditary diseases researches. Magnetic cell separation took a turn when, Zborowski, an Immunomagnetic Cell Separation (IMCS)

pioneer, analyzed commercial magnetic cell separation. Zborowski uncovered crucial revelations that were then used, and are still used today, in the human understanding of cell biology. Today, the manufacture of therapeutic products concerning cancers and genetic diseases, are being innovated due to these discoveries. Zborowski uncovered crucial revelations that were then used, and are still used today,Magnetic separation techniques are also used in microbiology. In this case, binding molecules and antibodies are used in order to isolate specific viable organisms, nucleic acids, or antigens. Magnetic separation techniques are also used in microbiology. In this case, binding molecules and antibodies This technology helps isolating bacterial species to identify and give diagnostics of genes targeting certain organisms. When magnetic separation techniques are combined with PCR (polymerase chain reaction), the results increase in sensitivity and specificity.

Table 4.3 Specification of Conveyor

Parameter	Specification
Size	1200mm and 916mm
Length	3000mm
Operating Temperature	250 Degree C
Magenet size	400*400*100mm

4.1.4 Bailing Machine

A baler, most often called a hay baler is a piece of farm machinery used to compress a cut and raked crop (such as hay, cotton, flax straw, salt marsh hay, or silage) into compact bales that are easy to handle, transport, and store. Often, bales are configured to dry and preserve some intrinsic (e.g. the nutritional) value of the plants bundled. Different types of balers are commonly used, each producing a different type of bale – rectangular or cylindrical, of various sizes, bound with twine, strapping, netting, or wire.

Industrial balers are also used in material recycling facilities, primarily for baling metal, plastic, or paper for transport. Due to the ability for round bales to roll away on a slope, they require specific treatment for safe transport and handling. Small round bales can typically be moved by hand or with lower-powered equipment. Large round bales, due to

their size and weight (they can weigh a ton or more) require special transport and moving equipment.

The most important tool for large round bale handling is the bale spear or spike, which is usually mounted on the back of a tractor or the front of a skid steer. It is inserted into the approximate center of the round bale, then lifted and the bale is hauled away. Once at the destination, the bale is set down, and the spear pulled out. Careful placement of the spear in the center is needed or the bale can spin around and touch the ground while in transport, causing a loss of control. When used for wrapped bales that are to be stored further, the spear makes a hole in the wrapping that must be sealed with plastic tape to maintain a hermetic seal.

Alternatively, a grapple fork may be used to lift and transport large round bales. The grapple fork is a hydraulically driven implement attached to the end of a tractor's bucket loader. When the hydraulic cylinder is extended, the fork clamps downward toward the bucket, much like a closing hand. To move a large round bale, the tractor approaches the bale from the side and places the bucket underneath the bale. The fork is then clamped down across the top of the bale, and the bucket is lifted with the bale in tow. Grab hooks installed on the bucket of a tractor are another tool used to handle round bales, and be done by a farmer with welding skills by welding two hooks and a heavy chain to the outside top of a tractor front loader bucket.

Figure 4.4 Bailing machine

The rounded surface of round bales poses a challenge for long-haul, flat-bed transport, as they could roll off of the flat surface if not properly supported. This is particularly the case with large round bales their size makes them difficult to flip, so it may not be feasible to flip many of them onto the flat surface for transport and then re-position

them on the round surface at the destination. One option that works with both large and small round bales is to equip the flat-bed trailer with guard-rails at either end, which prevent bales from rolling either forward or backward. Another solution is the saddle wagon, which has closely spaced rounded saddles or support posts in which round bales sit. The tall sides of each saddle prevent the bales from rolling around while on the wagon, as the bale settles down in between posts. so it may not be feasible to flip many of them onto the flat surface for transport and then re-position them on the round surface at the destination. One option that works with both large and small round bales is to equip the flat-bed trailer with guard-rails at either end, which prevent bales from rolling either forward or backward. Another solution is the saddle wagon, On 3 September 2010, on the A381 in Halwell near Totnes, Devon, UK an early member of British rock group ELO Mike Edwards was killed when his van was crushed by a large round bale. The cellist, 62, died instantly when the 600-kilogram (1,300 lb) bale fell from a tractor on nearby farmland before rolling onto the road and crushing his van. . so it may not be feasible to flip many of them onto the flat surface for transport and then re-position.

Table 4.4 Specification of Bailing machine

Parameter	Specification
Bale Size	12 *15*T
Bale Weight	25-30Kg Ferrous

4.1.5 Selector Switch

Selector switches are available in a variety of styles including illuminated, non-illuminated, and non-illuminated key operated. Styles offered range from maintained or spring return, incandescent or LED, and 3-50 amps. Work with a selector switch specialist to determine the best product for your application.This product overview focuses mainly on the construction and functionality of Non-Illuminated Selector Switches. The Non-Illuminated Selector Switch is represented in both the Selector Switch Diagram as well as

the Selector Switch Video Overview. Selector switches use cams in combination with contact blocks to provide a wide range of circuit openings and/or closings. In the following diagram, "X" designates a closed circuit (energized or "on") for a particular selector switch position, and "O" to designate an open circuit (not energized or "off"). The Non-Illuminated Selector Switch is represented in both the Selector Switch Diagram as well as the Selector Switch Video Overview. Selector switches use cams in combination with contact blocks to provide a wide range of circuit openings and/or closings. In the following diagram, "X" designates a closed circuit (energized or "on") for a particular selector switch position, and "O" to designate an open circuit (not energized or "off").. The fork is then clamped down across the top of the bale, and the bucket is lifted with the bale in tow. Grab hooks installed on the bucket of a tractor are another tool used to handle round bales, and be done by a farmer with welding skills by welding two hooks and a heavy chain to the outside top of a tractor front loader bucket.

Figure 4.5 Reject Conveyor II switch

Contact blocks are an integral part of selector switches. The contact block can have normally open (NO) and/or normally closed (NC) configurations. twice the

functionality to a switch because one switch operates two circuits. You can add multiple contact blocks to increase functionality. For example, you can mount 4 dual circuit blocks to a 30mm pushbutton for a total of 8 circuits. Dual circuits offer two contacts in a single contact block. The combinations include,

- 1 normally open and 1 normally closed contact
- normally open contacts
- normally closed contacts

Combinations with special delayed opening or early closing contacts.Dual circuit contact blocks save space in enclosures and add twice the functionality to a switch because one switch operates two circuits. a single circuit is an efficient, inexpensive way to get the job done.For example, you can mount 4 dual circuit blocks to a 30mm pushbutton for a total of 8 circuits.

Figure 4.6 Selector Switch

The automotive sector plants produced by BRIZIO BASI use multiple technologies, for: fluid treatment (brake systems, engine, etc.), Each system is designed by the engineers of BRIZIO BASI according to customer needs, and is entirely made at our factory. Contact blocks are an integral part of selector switches. The contact block can have normally open (NO) and/or normally closed (NC) configurations. Single circuits contain a contact block of either one normally open or one normally closed circuit. For applications that need only one contact, a single circuit is an efficient, inexpensive way to get the job done. Dual circuits offer two contacts in a single contact block. Indicating lights are part of selector switches. Setting a selector switch is how we tell machines how to operate.

Indicating lights tell us what the machine is do or failing to do. When a light is connected to a machine process, and the light is on, the machine shows that it's working. Contact blocks are an integral part of selector switches. The contact block can have normally open (NO) and/or normally closed (NC) configurations. Single circuits contain a contact block of either one normally open or one normally closed circuit. For applications that need only one contact, a single circuit is an efficient, inexpensive way to get the job done.

Table 4.5 Specification of Selector switch

Insulation Resistance	100 M ohms (min)
Contact Resistance	100 m ohms (max)

4.2 Software Specification

4.2.1 800 XA Control Software AC 800M Engineering

AC 800M control applications can be created in any of the five IEC 61131-3 dialects by using Engineering workstation, and then be downloaded to controllers using the Control Builder. Control applications can be distributed and executed on several controllers and communicate with each other on Control Network using named variable communication. Parts of the application can be downloaded to different controllers .The functionality range for control applications is wide, from binary control to closed loop control, with advanced functions like auto tuning PIDs, fuzzy control, etc. Pre-defined process objects like motor objects,valve objects, etc. are available. It is possible to build user-defined function blocks, and also to hide its content in order to protect the intellectual property. User-defined serial protocols can be developed in structured text with the support of special functions needed. The rich function block library includes several types of control loops, including advanced control and auto- tune capabilities as well as integration for ABB drives and motors. The controller communication by means of Ethernet includes on board RNRP redundancy along with a broad set of communication modules to connect to third-

party devices. A superior redundancy concept allows for fast switch-over times and topologically separated CPU-modules. Several CPU modules are available, varying in terms of processing power, memory size and redundancy support. Priority controlled, time-based tasks allow the highest stability control tasks.Supporting standard IEC 61131-3 programming languages, Compact Control Builder is the tool for engineering the control code and the hardware layout of AC 800M. It creates logic, sequential and analog control-intensive automation solutions for all existing controllers in the automation system to be handled in one database. The flash memory card allows loading applications without the need to utilize the engineering tool to support OEM and remote solutions.The AC 800M for Compact Control Builder is a family of PACs built as rail - mounted modules, consisting of CPUs, communication modules, power supply modules and various accessories. There are 7 CPUs to choose from, ranging from medium processor power and low cost to high processor power and support for full redundancy. Compact Control Builder is the tool for engineering the control code and the hardware layout of AC 800M. It creates logic, sequential and analog control-intensive automation solutions for all existing controllers in the automation system to be handled in one database.

4.2.2 Benefits

- Full modularity and flexibility for all environments for future expansion of control applications
- Compact Control Builder software offers a wide range of powerful control solutions and reusable libraries for efficient configuration
- Robust design and redundancy options in all critical areas of the controller and its components eliminates single-point failures and secures maximum availability
- Supports a broad range of I/O products that can be integrated into a spectrum of industrial processing applications.

4.2.3 The programming languages

4.2.3.1 Function Block Diagram

Function Block is a graphical language for depicting signal and data flows by means of library-stored software elements and interconnecting signals. Function block programs are easy to develop and, thanks to the resulting graphical diagrams, also easy to

read. Many specific types of functional block diagrams have emerged. For example, the functional flow block diagram is a combination of the functional block diagram and the flow chart. Many software development methodologies are built with specific functional block diagram techniques. An example from the field of industrial computing is the Function Block Diagram (FBD), a graphical language for the design of programmable logic controllers. The functional block diagram can picture,

- Functions of a system pictured by blocks
- input and output elements of a block picured with lines
- the relationships between the functions, and
- the functional sequences and paths for matter and or signals

4.2.3.2 Structured Text

Structured text (ST) is a high-level programming language. It has a comprehensive range of constructs for assignments, function calls, expressions, conditional statements, iterations, etc. ST lends itself well to writing advanced, compact - yet easily understandable - programs thanks to its logical and structured layout. It has a comprehensive range of constructs for assignments, function calls, expressions, conditional statements, iterations, etc. ST lends itself well to writing advanced, compact - yet easily understandable - programs thanks to its logical and structured layout.

4.2.3.3 Ladder Diagram

Ladder diagram (LD) is a graphical language based on relay ladder logic. Hence it is suitable for those who prefer to define interlocks and control actions in terms of relay contacts and coils, and other functions as "black boxes".

4.2.3.4 Sequential Function Chart

Sequential function chart (SFC) is a graphical language for depicting the sequential behavior of a control system. It is used for defining time- and event-driven control sequences.

4.2.3.5 Instruction List

Instruction list (IL) is a low-level, execution-efficient PLC language where each statement corresponds to a single or only a few processor instructions. It has a structure similar to Assembler. Instruction List (IL) is one of the 5 languages supported by the initial versions of IEC 61131-3 standard, and subsequently deprecated in the third edition. It is designed for programmable logic controllers (PLCs). It is a low level language and resembles assembly. All of the languages share IEC61131 Common Elements. The variables and function call are defined by the common elements so different languages can be used in the same program.Program control (control flow) is achieved by jump instructions and function calls (subroutines with optional parameters).The file format has now been standardized to XML by PLCopen. Many vendors whilst incorporating the full IEC 61131-3 requirements have additional vendor specific calls/function blocks to suit their hardware such as reading or writing to I/O. Siemens PLC instruction list language is known as "Statement List" or "STL" in English, and "Anweisungs-Liste" or "AWL" in German, Italian and Spanish. The user of a Simatic development package may choose between German and International mnemonics to represent instructions. For example, "A" for "AND" or "U" for "UND", "I" for "Input" or "E" for "Eingang". It was from the automotive industry in the USA that the PLC was born. Before the PLC, control, sequencing, and safety interlock logic for manufacturing automobiles was mainly composed of relays, cam timers, drum sequencers, and dedicated closed-loop controllers. Since these could number in the hundreds or even thousands, the process for updating such facilities for the yearly model change-over was very time consuming and expensive, as electricians needed to individually rewire the relays to change their operational characteristics.

4.2.4 Program Changes

4.2.4.1 Configuration and Downloading

Applications can either be loaded into the target controller(s) by non-volatile Flash memory cards or over a serial link or The former approach is suitable for smaller and more standardized As it is based on IEC61131-3 and various standard fieldbus options are included, you will experience more freedom in designing your application.Ethernet network into battery backed-up RAM. The former approach is suitable for smaller and more

standardized duties where users can be spared involvement in the application software development and handling process.

4.2.4.2 Program Structure

You are gaining engineering productivity as there is only one tool covering the entire range of AC500 PLCs, from the compact AC500-eCo, the scalable AC500 including the safety PLC to the high availability and extreme conditions variants. Applications can either be loaded into the target controller(s) by non-volatile Flash memory cards or over a serial link or Ethernet network into battery backed-up RAM. The former approach is suitable for smaller and more standardized As it is based on IEC61131-3 and various standard fieldbus options are included, you will experience more freedom in designing your application.

4.2.4.3 Advantages

- Easy and fast programming in all IEC61131-3 languages plus CFC.
- Parameterization of all PLC I/O, network and fieldbus modules with specific device editors.
- Diagnostics is set up automatically for online monitoring of inputs and outputs.
- Debugging & diagnostics with multiple, comprehensive watch lists.

CHAPTER 5

SIMULATED RESULT

5.1 Simulated Result

In industries DCS controller, Separate conveyor ,waste material selection, metal separator are install physically on field. Using the control builder we creating the powerful control solution.It's done in a Windows based environmental,offering a wide range of control functionality for ABB's industrial controller AC800M.

CHAPTER 6

CONCLUSION AND FUTURE ENHANCEMENT

6.1 Conclusion

In here we have introduced the another reject conveyor for controlling the reject material levels during increase waste material. The reject conveyor II is plays the major role in our project. Here the reject handling conveyor II is used to saving the time and controlling the environmental impacts and reducing the more manual power and it's furtherly used some other purpose like cementplant,scrap yard.

/874 
Figure 6.1 Reject Handling System

6.2 Future Enhancement

Future implementation of this reject handling system can be further enhancement of increasing the capacity of conveyor I and conveyor II, which is used to handle the reject materials properly and also now we bundle the reject material with the help of human being. In future may be we will make automatic Bailing machine which is used to handle the reject material automatically.

ABSTRACT

The main objective of this project to dispose the reject material properly and reduce the environmental impacts. This is a Deinking process (DIP). Deinking process is the one in which the ink from the office waste and newspaper and removed in order to prevent it from dispersion into the pulp sodium soap is used for removing the ink. The sodium soap produced in conveyer. The existing method have only one conveyer. It carries the reject material and it create the environmental hazards. But our proposed method has two conveyers. These conveyers are worked with the help of DCS. It reduces the environmental pollution and reduce the need for more manual labor. The conveyer 1 has a magnetic separator which separate the metal, iron and its components. The conveyer 2 has a reject material like polythene and reject material. Those materials are conveyed Baling machine by using the conveyer 2. Finally, all the reject materials are bundled by using the baling machine.

I. INRODUCTION

A distributed control system is a computerized control system for a process. It has many control loops. A distributed throughout the system with each component sub-system controlled by one or more controllers. The control systems is connected to the communication medium. It is used to monitoring the networks. DCS is a broad term. It is used in many types of application. Its monitor and control the distributed components. Beginning of the DCS devices that controlled process and turned valves on the site modeling of the system is made by DCS and it allow the ability to record and managing process. Because DCS is used to control process control remotely and gain of how they can be improved to both increase safety and profit and how the process operates the possibilities. Transmit information is used to find the output of the instrumentation in field. In this process we are using electrical buses and multiplexer buses. It connects to the processor and modules and multiplexer buses are connected to the central controller to distributed controller. It is used in HMX (human-machine interface). DCS system are deployed in operations may cause material and personnel losses. Increasing the investments to the control system to prevent the possible to include redundant solution. Redundancy are nowadays standard built in options for DCS and also its not necessary for them to write a custom program. It is related with online and offline applications changes. A DCS acts to run non-stop for gears. DCS (distributed control system) systems denoted as dedicate systems. It is used to manufacturing processes. central station power generation is used to generate the power. It is also used to more application like cement production, paper making and steel making. The most popular example is a setpoint control loop which consist of pressure sensor, controller and control valve. The flow measurements are transmitted in signal controlling of input/output(I/O) device.

II. PROPOSED SYSTEM

In this proposed method, the waste paper is obtained from the waste products. It has two reject conveyors. The two reject conveyors are connected in serious connection. The two reject conveyors are operated in based on time. The reject conveyor I consist of metal separator which is used to separate the metal from the reject wastage. Then the reject waste material is passed through the bailing machine with the help of reject conveyor II. The reject conveyor II carries the waste materials such as polythene and etc. The metal separator attracts the metals and iron components. The obtained metals are passes to the scrap yard. In this scrap yard this metal is melted and its used to reproduce another metal product. The polythene papers are sent to the kiln and its used in cement plant for raise the temperature. The reject conveyor II having the waste papers which is passes to the

bailing machine. After receiving the bailing machine, the papers are compressed and its bundled with the help of iron strip. Then the reject conveyor I and reject conveyor II works at simultaneously before filling the bailing machine. When the bailing machine was filled the reject conveyor II works based on the timer, we set the run time and stop time

III. HARDWARE IMPLEMENTATION

A. MOTOR (3PHASE)

A electric motor converts the electrical energy into mechanical energy which has different types of loads. A.C (Alternating Current) motors operates on a power supply which has classified into

- Synchronous motor
- Single phase motor
- 3phase motor

When a 3phase induction motors are most widely used for industrial applications mainly because they do not require any starting device.

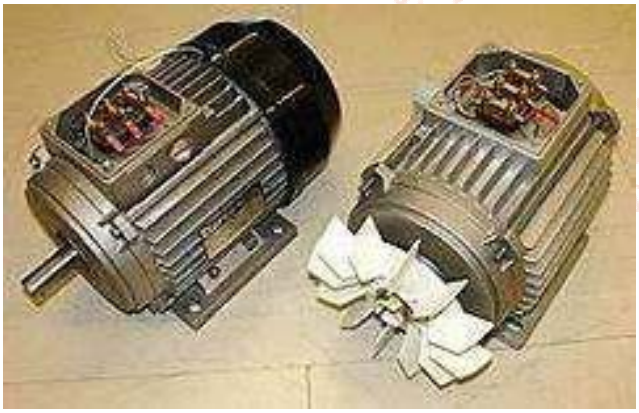

Fig2. Motor (3Phase)

In an 3phase induction motor, the rotor current is introduced by the magnetic field, instead of electrical connection. The principle of this motor is based on the production of RMF. (rotating magnetic field) which is used to rotates the motor at synchronous speed. The direction of rotation of the motor is depends on the sequence of supply lines and these lines are connected to the stator. Motors are commonly configured to have 2,4,6 or 8 poles.

Synchronous speed of rotation = (120*supply frequency) / Number of poles on the stator

B. CONVEYOR

A conveyor belt is used to carrying medium of a belt conveyor system. The many types of conveyor based upon the work. A belt conveyor is one of the conveyors. In this belt conveyor system having of two or more pulleys. It's carries the medium conveyor belt that rotates. These two pulleys are more powered. It moving the belt and these material passes to the forward direction. There are two types of pulley available one is Powered pulley another one is Unpowered pulley.

This Powered pulley is known as drive pulley and Unpowered pulley is known as idler pulley. This material is used to transport large volume resources. Finally, it produced agriculture material like sand, ore, coal, salt, grain and etc., Transport product through changes in elevation or Its direction by using belt conveyor. It produces the bulk materials like grains, coal, sand and ore etc.,

Fig3. Conveyor

C. MAGNETIC SEPERATOR

A magnetic separator is a device which is used to remove the impurities and magnetic materials. It can be used to make the production of a materials and It can be adjusted to attract different types of materials at different intensity levels. It is use almost industrial in nature. A magnetic separator is used for variety of application. It can be ferromagnetic or paramagnetic and It can vary in size. Heavy drum used in recycling and more manufacturing application.

Fig4. Magnetic Separator

D. BAILING MACHINE

A bailing machine is used to bundle the waste material with help of humans. A baler is called hay baler is used to compress a cut and raked crop. The compact baler is easy to handle. Transport and store bales to preserve by using some intrinsic valve plants are bundled. Each of the plants producing a different type of bale which is find out in cylindrical of various size, strapping. the different types of balers are used in this method of bailing machine Due to this ability for bales. They require specific treatment for safe transport and handling.

Fig5. Bailing Machine

E. SELECTOR SWITCH

Selector switches are available in various of styles and also it has illuminated, non-illuminated key operated. The styles offered range from maintained or sprains return and 3-50 amps. The selector switch work with specialist to determine the best product for your application. In this product is mainly focus on the construction and functionality of non-illuminated selector switches.

Fig6. Selector Switch

IV. SOFTWARE IMPLEMAENTATION

A. 800 XA CONTROL SOFTWARE AC 800M ENGINEERING

AC800M control application can be created in any of the five IEC 61131-3 dialects using the control bulider. It can be downloaded to controllers using the control builder. It can be distributed and excuted on several controllers and control network using named variable communication. Part of the application can be downloaded to different controllers. The fuctionality range for control application is wide and it's control to closed loop control with more advanced functions like fuzzy control, auto tunning PID, etc., Predefined process objects like valve objects, motor objects, etc., User define function block are possible to build and also to protect the intellectual property. User define serial protovals can be developed in structured text and it's support the special fuctions needed.

It have several type of control loops, including advanced control and auto tune capabilities as well as integration for ABB drives and motors. The controller communication is an ethernet. It's includes on broad RNRP redundancy. This broad set of communication modules is connect to third party devices. Superior redundancy allows for fast swich-overtimes. In this superior redundancy topologically seperated CPU modules and It have several CPU modules available. It varying the terms of processing power, memory ize and redundancy support.

Fig7. Control Builder Logic 1

V. CONCLUTION

In here we have introduced another reject conveyor for controlling the reject material levels during increase waste material. The reject conveyor II is playing the major role in our project. Here the reject handling conveyor II is used to saving the time and controlling the environmental impacts and reducing the more manual power. Then the reject material passes to the bailing machine and it's furtherly used some other purpose like cement plant, scrap yard.

ABSTRACT

The main objective of the project is to stabilize the gun against the disturbances and to position the gun precisely against the target as well as to control the rate of the gun. All ac electrical gun control system is composed of permanent magnetic synchronous machine driven control system and ball-screw by replacing the complicated electro hydraulic systems. At the same time, the variable-structure system sliding modes makes the gun control system to have higher performances using the only rate flexure gyroscope. Elevation axis model of a barrel stabilization system is constructed. The nonlinearities which are considered in the model are orifice flow characteristics, coulomb friction, hard-stop limits, kinematics of the system and unbalance on the barrel. A Simulink model for the servo valve, actuation system and barrel is constructed. Servo valve identification is made via the actual test data. Compressibility of the hydraulic fluid is taken into consideration while modeling the actuation system. Friction model is simulated for different cases. Controller of the system is constructed by two PIDs, one for each of the velocity and the position loops. Velocity feed forward can reduce the time to make a quick move by the system. The disturbance is evaluated from a given road profile and disturbance feed forward is applied to the system.

CHAPTER 1

INTRODUCTION

1.1 Introduction

Weapons used in the battlefield are demanded to be lighter, more mobile, easily controllable and able to shoot with a high accuracy. One of these weapons used in land is the Main Battle Tank (MBT). MBT is probably the most important weapon because of its being mobile, armoured and having heavy-fire capacity. Developments of MBT are parallel to the improvements in heavy weaponry, Weapon Control Systems (WCS) and hull mobility. Heavy weapons have became more effective with the improvements in material science and chemistry. Mounting of these weapons to the hull produces some problems. Control systems become more important while the system become larger and more complex. Drive technology and control systems determine the size of the MBT. Hull mobility depends on the vehicle technology to overcome the problems of cross-country movement. Mobility demands in battlefield lead to the requirement of firing while moving instead of stopping at each time the MBT engages a target. This demand can be achieved by WCS by minimizing the tank's hull movement effects on the barrel.

This is followed by the use of hydraulic drive systems. After electrical motors were used for slewing the barrel, rapid and precise control has been satisfied. Improvements in traversing the turret were applied to the powered control of the elevation control of tank guns. This adoption has led to the stabilization of the barrel.

1.2 Stabilization of Barrel on a Main Battle Tank

Motion of vehicles causes some unwanted movements on the barrel. These movements must be minimized in order to hit a target while moving.

Gunners are expected to minimize this effect especially in elevation by rotating the barrel in the opposite direction of the hull's motion. But the frequency of this kind of motion varies from 0 to 3- 4 Hz while the response of the human operators is not more than 0.5 Hz.

In this situation, the effects of vehicle motion on the barrel can be minimized by stabilization systems which are designed to maintain the barrel position according to the earth. Figure 1 and Figure 2 illustrate the problem in detail.

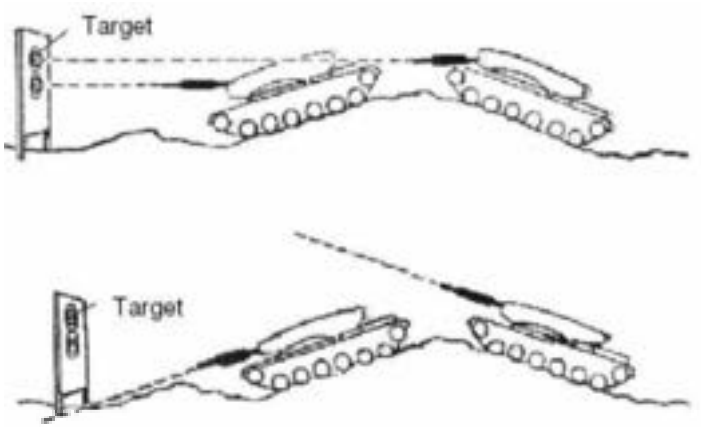

Figure 1.1 Barrel Motion in Elevation

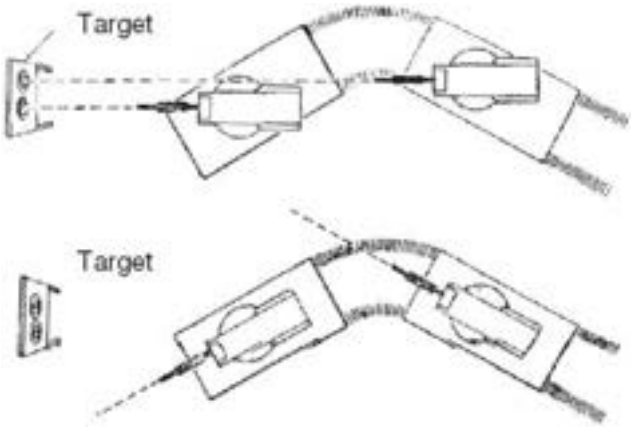

Figure 1.2 Barrel Motion in Azimuth

In 1998, Purdy enhanced the stabilization ratio by using the hull rate gyroscope for feed forward. This study gave the results of the simulations of linear and nonlinear model with and without disturbance feed forward and nonlinear model with feed forward and friction compensation. In another study in 1999, Purdy made a simple elevation model and examined the out of balance effect on WCS. These studies deal about the electrical drive technology. They also have no model in a computer program revealed in the publications.

Systems aimed to do this stabilization basically closed loop servo systems which control the movement of the barrel relative to the earth by using gyroscopes and feedback signals produced by them. Simplest stabilization systems are assigned to cope with the elevation changes and made up of a single closed loop system with a rate gyroscope mounted on the barrel to sense its angular velocity.

For the existing gun systems without making substantial modifications, MRS could be useful in controlling the deflections of gun barrels with estimation/prediction algorithms. The vibration levels could be cut into half by the use of optimised vibration absorbers for an existing gun. A new gun system with a longer barrel can be as accurate as the one with a short barrel with the appropriate structural modifications.

Tank stabilizer is a control system keeping the bore axis in the desired sighting angle. For the control problem of the stabilizer in the case of uncertain parameters, the adaptive control method is introduced to design the vertical tank stabilizer with the nonlinear dynamic model of vertical stabilizer given in the paper. In the design, the multiple parameter uncertainties of the hydraulic servo system are fully considered and the linear feedback control is used to improve the asymptotic stability of the system. The vertical stabilizer of tank is simulated in MATLAB/Simulink environment.

CHAPTER 2

LITERATURE REVIEW

2.1 Hydraulics Control System

2.1.1 Introduction

The stabilization of the barrel on a MBT in elevation axis is considered. Only the elevation axis is considered because it is affected much more than the azimuth axis from the road profile. Since a stabilization system improve an ability of hitting targets while the tank is moving without stopping, the effects of disturbances on the barrel should be taken into account.

Sometimes modelling so many details becomes harmful instead of being helpful as the system may not be settled with the desired accuracy because of the problems mentioned above. While modelling, critical case is to determine the modelling criteria and assumptions. While constructing the elevation axis model, the following assumptions are made:

- There is a stable source of hydraulic fluid supply at constant pressure.
- Effects of hydraulic fluid inertia are negligible.
- Gage pressures are used.
- No temperature change exists.
- There is no leakage.

2.1.2 System Model

In this study, the "system" will represent the union of the servo valve, the actuator and the barrel. Hull dynamics is not included in the system mentioned in this study. While it is assumed that road profile is known and correctly transformed via the gyroscopes on the hull, it is included in the system

as disturbance representing the hull motion.

2.1.3 System Identification
